Fort Irwin
Desert Tortoise Protection Project Report

January 5, 2009

During fiscal year 2008, USDA APHIS Wildlife Services entered into an agreement with Fort Irwin Army National Training Center. The main objective of Wildlife Services efforts was to protect the threatened and endangered desert tortoises from predation by coyotes in the Southern Expansion Area of the Fort Irwin Desert Tortoise Translocation Project.

On May 19, 2008, an initial site visit was made by Wildlife Services employees. Wildlife Services met with Fort Irwin employees to discuss the goals and expectations of the desert tortoise protection project but was denied permission to lethally remove coyotes until further notice. On May 20, 2008, Wildlife Services was given permission to lethally remove coyotes and began setting equipment and spotlighting to initiate tortoise protection from depredating coyotes. Fourteen padded foothold traps were set to target depredating coyotes. On May 21, 2008, an additional seven traps were set. On May 22, 2008, all foothold traps were removed. Due to adverse weather, no coyotes were removed at this time.

On July 29, 2008, Wildlife Services was again contacted by Fort Irwin and requested to submit an estimate for two weeks of predator control. Wildlife Services wrote a cost estimate for a two week time period and filed the appropriate NEPA paperwork to conduct predator control. On August 12, 2008 Wildlife Services met with the Deseret Tortoise Recovery group to discuss protection of the species, and it was determined at this time that the recovery group was not ready to initiate predator control.

On August 18, 2008, a second site visit was made and equipment was set. From August 18th through the 26th, twenty-seven padded foothold traps were set. Two coyotes were removed during this two week control effort, one with padded foothold traps and the other by calling and shooting. One bobcat was captured in a padded foothold trap but was released unharmed upon discovery. On August 29, 2008, Wildlife Services completed the two week desert tortoise protection protect.

Wildlife Services personnel spent a total of 253 hours conduction predator control efforts and associated administrative duties. A total of 182 trap nights, 10 call stands and three nights of spotlighting were conducted in an effort to remove coyotes in areas in and adjacent to desert tortoise translocation plots. A trap night is defined as one trap set for one night. Two traps set for one night would be considered two trap nights, etc. A call stand is an attempt to lure a predator to a specific location with the use of distress sounds in an attempt to remove an offending animal. Spotlighting is done by shining a spotlight from a vehicle in an attempt to locate the eye shine of a predator and lethally removing that predator once positive identification can be made.

On October 29, 2008, Wildlife Services met with the Desert Tortoise Recovery group and it was determine that a four year agreement be set to protect the desert tortoise

from depredating coyotes. Wildlife Services has put together all necessary paperwork and posted the position in order to fulfill this agreement.

During the 2009 fiscal year, Wildlife Services would like Fort Irwin, the Desert Management Group and the BLM Barstow Field Office to continue to monitor and report all depredation losses and coyote activity. Feel free to contact the San Luis District Supervisor, Eric Covington, at (661) 765-2511 with any questions concerning the Fort Irwin Desert Tortoise Protection Project.

Eric Covington
District Supervisor
USDA Wildlife Services

The Desert Tortoise Recovery Office (Service 2014) used these annual density estimates to evaluate range-wide trends in the density of desert tortoises over time. This analysis indicates that densities in the Northeastern Mojave Recovery Unit have increased by approximately 13.6 percent per year since 2004, with the rate of increase apparently resulting from increased survival of adults and subadults moving into the adult size class. The analysis also indicates that the populations in the other 4 recovery units are declining: Upper Virgin River (-5.1 percent), Eastern Mojave (-6.0 percent), Western Mojave (-8.6 percent), and Colorado Desert (-3.4 percent; however, densities the Joshua Tree and Piute Valley conservation areas within this unit seem to be increasing). The following figure shows linear trends in the log-transformed densities in each desert tortoise conservation area by recovery unit. Data for the Upper Virgin River Recovery Unit are from 1999 to the present; data for all other recovery units are from 2004 to the present.

(I did not include your figure here but it will be in the biological opinion.)

Allison (2013) also evaluated changes in size distribution of desert tortoises since 2001. In the Western Mojave~~, Eastern Mojave,~~ and Colorado Desert recovery units, ~~the median size of large individuals has increased, indicating less recruitment of younger (therefore smaller)~~the relative number of juveniles to adults indicates that juvenile numbers are declining faster than adults. In the Eastern Mojave, the number of juvenile desert tortoises is also declining, but not as rapidly as the number of adults (Allison, *personal communication*). ~~In the Western Mojave and Colorado Desert recovery units, the relative number of smaller desert tortoises is about half what it was in 2001. Taken together, these trends suggest fewer small desert tortoises are reaching sexual maturity, which may be explained because they comprise a smaller proportion of the population or possibly because their survival rates are relatively lower than those of adults. Either possibility indicates that smaller size classes, like adults, are affected by ongoing threats; however, because most small desert tortoises die before reaching 180 millimeters in length, we do not know whether the reduced number of small animals has directly contributed to the observed declining trends in adults. For instance, a small increase in adult mortality would have a much larger effect on adult densities. None of these demographic rates have been measured in parallel with this study, so we cannot point to specific demographic rates that are associated with these overall population declines.~~In the Upper Virgin River Recovery Unit, trends in juvenile numbers are similar to those of adults, while in the Northeastern Mojave Recovery Unit, the number of juveniles is increasing, but not as rapidly as are adult numbers in that recovery unit (Allison, *personal communication*). It is clear that juvenile numbers, like adult densities, are responding in a directional way, with increasing, stable, or decreasing trends, depending on the recovery unit where they area found.

As an aside, we have been including the following section in which we attempt to bring anthropogenic impacts into the acreages provided by habitat model. In the March 2014 white paper, how did you use the model? I.e., did you cut the acreage off at 0.5? Do your numbers of desert tortoises reflect the loss of shown in Xian? I was going to use the table in the March paper but I am concerned that we could be driving people (and ourselves) crazy if we are using all sorts of different methodologies. The explanation under the table says we used "all" modeled habitat. To me, that implies we went all the way down to 0.1 and included impervious surfaces. I think that would greatly inflate the estimated number of desert tortoises that are out there. Which makes me wonder what value we used in the following table that has been in all our biological opinions. Hmmm.

The following table depicts acreages of habitat (as modeled by Nussear et al. 2009) within various regions of the desert tortoise's range and of impervious surfaces as of 2006 (Xian et al. 2009). Impervious surfaces include paved and developed areas and other disturbed areas that have zero probability of supporting desert tortoises.

Comment [A1]: I used these same numbers from columns 2 and 3. I applied estimated 2004 and 2012 densities for each recovery unit to the area in column 2 – area in column 3. The exception is that your table only has one recovery unit for both the Northeastern Mojave and Eastern Mojave; this was contemplated at one time, but the 2011 recovery plan has 5, not 4 recovery units. In the table, I indicate the numbers I used for the 2 separate RUs.

Regions[1]	Modeled Habitat (acres)	Impervious Surfaces within Modeled Habitat	Percent of Modeled Habitat that is now Impervious
Western Mojave	7,582,092	1,864,214	25
Colorado Desert	4,948,900	494,981	10
Northeast Mojave	7,776,934	1,173,025	15
Northeastern Mojave	3,013,677	378,497	
Eastern Mojave	4,763,257	794,546	
Upper Virgin River	232,320	80,853	35
Total	20,540,246	3,613,052	18

[1]The regions do not correspond to recovery unit boundaries; we used a more general separation of the range for this illustration.

Attachments: Questions to Linda about incorporating March 2014 into a BO_lja.docx

---

OK, I read your attachment and have provided some tracked changes. I no longer use the analysis of shifts in size of juveniles and just stick with trends in the proportion of juveniles relative to adults. Since this was only briefly touched on in the March 2014 paper, I added some Allison (pers comm) statements, if you really want them. I assume you should stick with the sentences that don't use the Allison (pers. comm.) citation, but provide them for your reading pleasure.

Finally, your concern about how I calculated areas for each recovery unit turns out to be unwarranted. I used exactly the same numbers as in your table (we both work with Cat, after all!), although your table is based on only 1 recovery unit for both the Northeastern and Eastern Mojave recovery units. That was once considered but we went back to 5 recovery units for the 2011 recovery plan revision. (I added numbers to the table to show you how we now split out areas for Northeastern and Eastern Mojave RUs.)

Again, let me know if any questions,

Linda

> Hi Ray and Ray,
>
> I will get to the attachment you sent, but wanted to answer a couple of the embedded questions now.
>
> How did I get the population estimates for 2004 and 2012? The trend estimates give me specific density estimates for each year and in each recovery unit. I focused on the earliest starting year common to all recovery units (we had earlier data for Upper Virgin River, but for all RUs by 2004) and the latest year covered by our estimates (2012). To apply these tortoise densities for each recovery unit to areas outside of TCAs, I estimated the area of potential habitat based on Nussear et al. (2009). Their model assigns probability of occupancy to 100 ha grid cells. We only considered areas assigned a probability of occupancy > 0.5 as potential habitat (Liu et al. 2005), and removed any area identified as an impervious surface due to human construction activities (Fry et al. 2011). So density X area = population estimate. That this is extrapolating outside of the area I actually sampled, and there are actually probably fewer tortoises outside of TCAs than this method indicates, but this is a reasonably way to describe overall population changes. For instance, it shows how a population increase in the relatively small NE Mojave Recovery Unit does little to compensate for the absolute number of tortoises that must be gone when we apply the population trend for the Western Mojave to such a relatively large area.
~~~~~~~~~~~~~~~~~~~~~~~~~~~~

What summary information should be used for juvenile trends? I would definitely use the MOG summary sheet, not the earlier summary, although I haven't been able to find a copy of what I gave you. Until early 2014, I was trying to use nonparametric statistics to describe juvenile trends, but "*non*-parametric" means I can't estimate the *parameter* (the change in juvenile relative abundance). So I was able to describe whether trends went up or down, but not by how much - not very useful for wildlife conservation. Please use only my recent summaries because these will be consistent with the path forward from here.

I'll look at that attachment you sent now, but if you have questions about the stuff above, let me know,

Linda

> Greetings. We have a couple more biological opinions almost ready to roll out. In them, we are summarizing the March 2014 trend white paper and using that summary to replace the info you gave us before in an email on trends. That led me to wonder if we should use the short discussion in the March 2014 paper about recruitment to replace other info that we received from you via email during the Stateline consultation. Last, I am wondering how you derived the overall numbers of desert tortoises from the March 2014 paper.
>
> I attached this rewrite; can you take a look to see if it makes sense, please? I did not try to do anything in terms of summarizing the table showing the overall numbers of desert tortoises; I have too many questions to start on that yet.
>
> I will be out this week except for a brief time on Monday morning. Maybe I can catch you to discuss before I take off. Could you please send your thoughts to Ray V also? We are hoping to move his biological opinion out the door a bit wheile I am on leave.

The Other Ray

P.S. Is it too early on Monday for me to ask questions like this?

AVIAN MORTALITIES AT SOLAR FACILITIES

Amedee Brickey

April 14, 2014

Background

- CA/NV Desert – Few facilities prior to 2009
- Solar Development driven by:
  - Financing incentives (Grants, Loans Guarantee, Tax Breaks)
  - State RE Portfolio Standards

Background

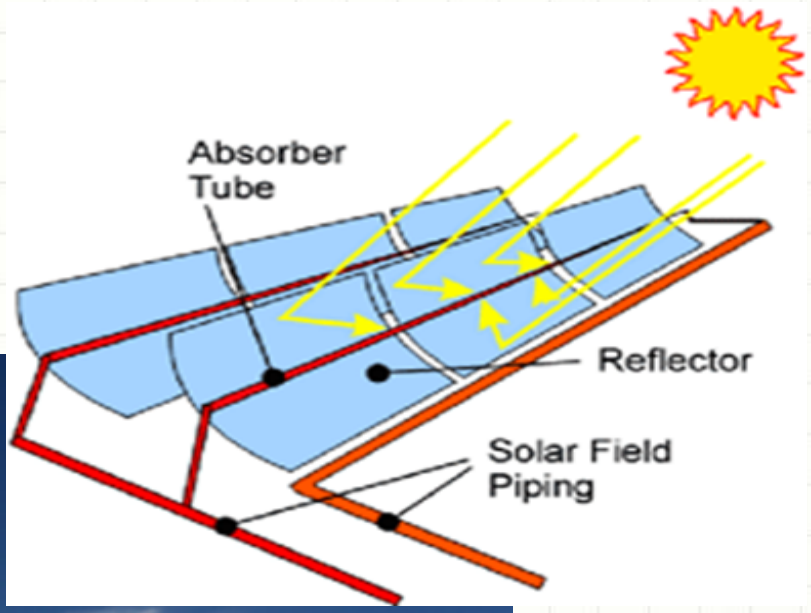
- Older Solar Facilities (prior to 2009)
  - Mostly on private land
  - No systematic mortality monitoring
  - No reporting requirements

California RE Action Team

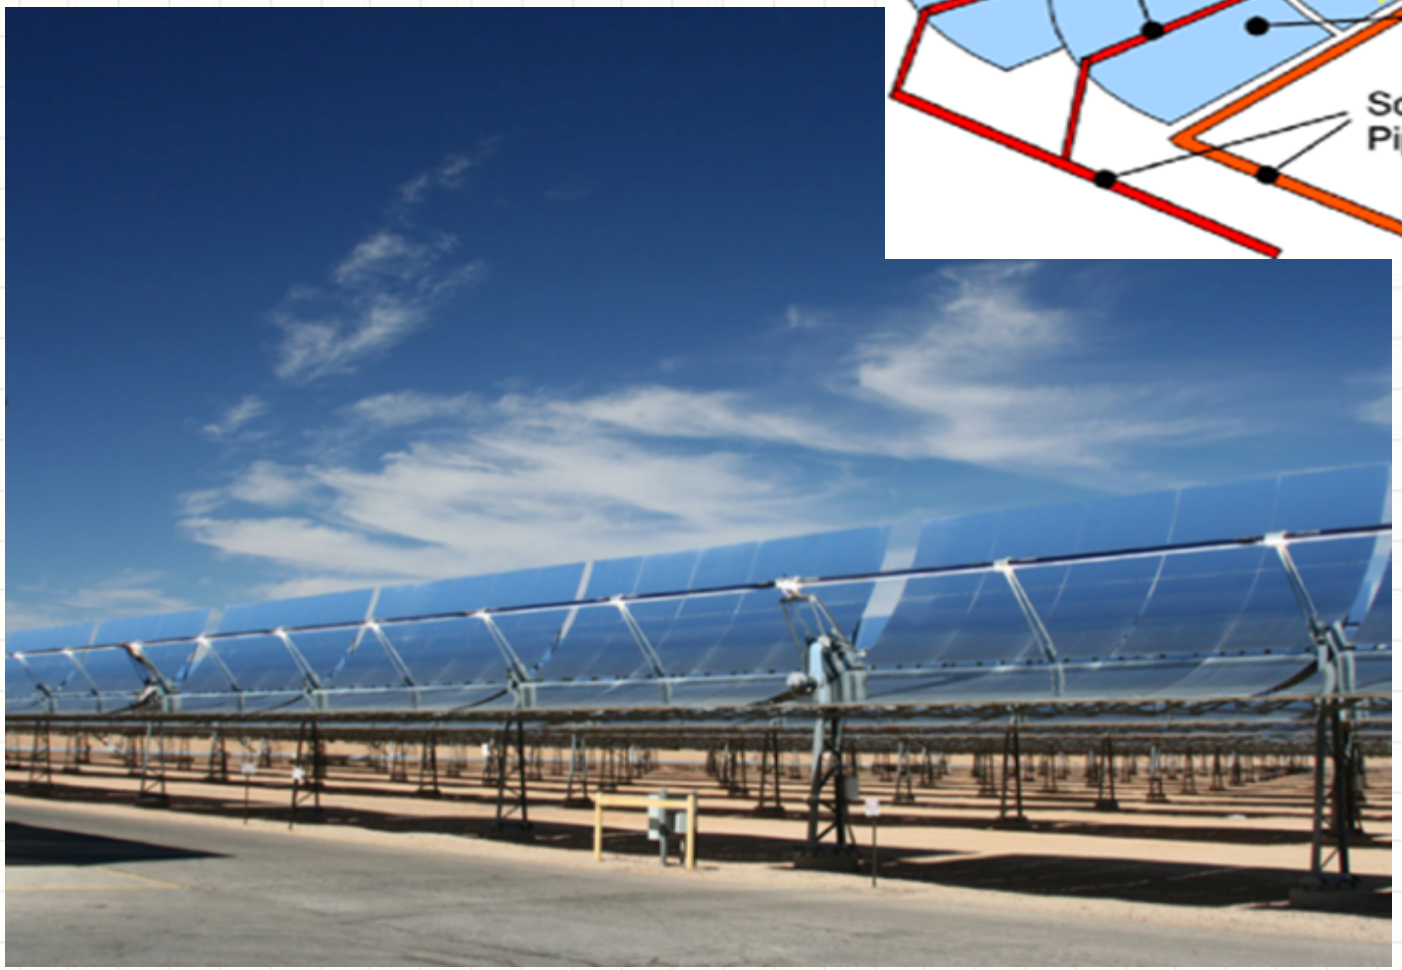
- Renewable Energy Action Team (REAT)
  - Established in 2009
  - Streamline agency review and permitting
- FWS worked with BLM and CEC
  - Require development of ABPP/BBCs
  - Agency review of documents

Project-level Avian Plans

- ABPP/BBCS include:
  - Measures to avoid take during construction
  - Systematic mortality monitoring
  - Reporting requirements
  - Some include adaptive management



Mortality Information



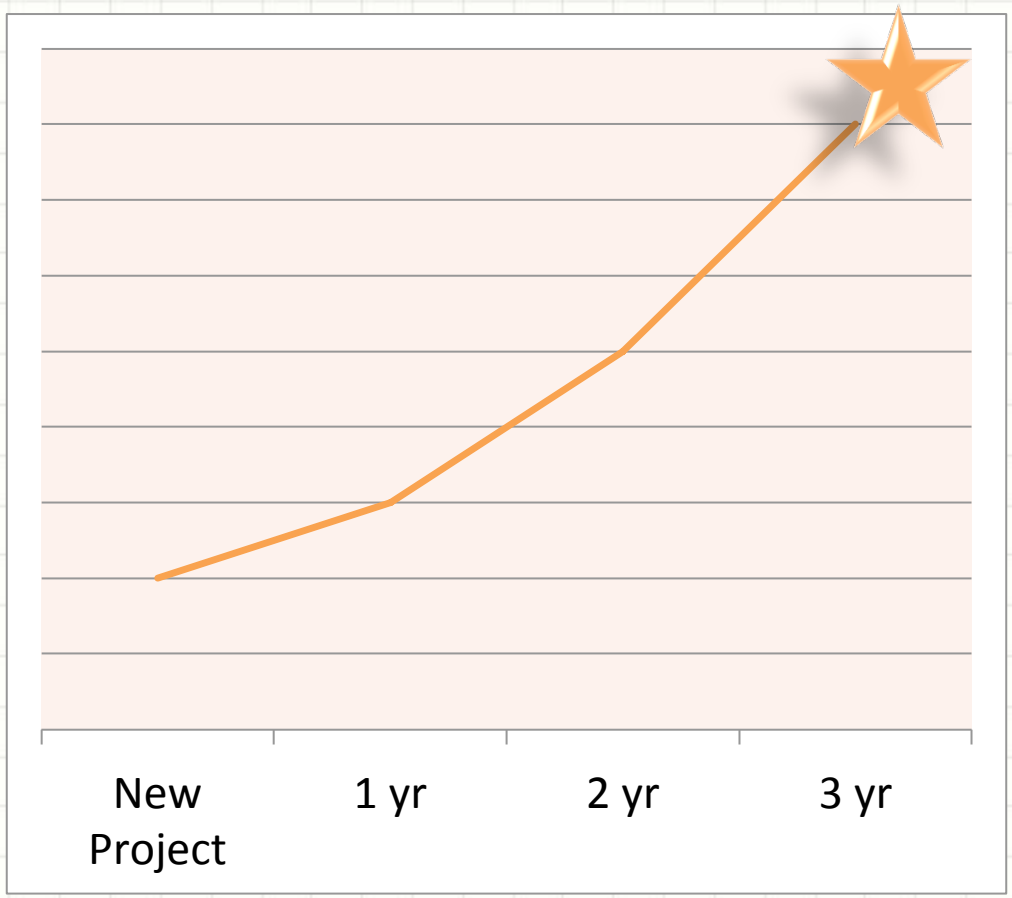
- Database created to track injury and mortality
- Collisions will panels and other project features
  - All 3 solar technology types
  - Wide range of avian species affected

Photovoltaic

Parabolic Trough

Power Tower

Concentrated Solar Flux Effects



- ISEGS fully operational for less than 6 months
- Incidental reporting (raptors, passerines, humming birds, butterflies, etc.)
- First quarterly report expected in May 2014

Concentrated Solar Flux Effects

Why - Cause and Effect

Our learning curve

It may take 2-3 years to answer some questions

Status

- Meetings with Solar Developers
  - September 2013
    - Discussed avian mortality concerns
  - February 2014
    - Discussed avian mortality data summary
    - Discussed research needs
    - Encouraged developers to get organized and help collect needed information to address avian collisions.

Summary

- Collaboration between industry and agencies will be needed to address the avian mortality issue.
- A framework that includes funding for research, adaptive management, and the eventual development of best management practices.
- Other stakeholders will need to be included.

QUESTIONS?

From: Tera Baird
To: kmarsden@blm.gov
Subject: 10a1A Permit/McCoy Project
Date: 06/29/2012 01:41 PM

Kim:

Here is some info about attaching transmitters, marking (notching) and/or performing health assessments on desert tortoises located on the NextEra McCoy project under an existing 10a1A permit prior to the issuance of a BO. After discussing this issue with members of the DTRO here is what we decided:

1. Conducting disease testing early in the process under a recovery permit would be useful information and help us develop better translocation plans
2. The latest version of the translocation guidance indicated that it would be possible to conduct "pre-project" activities under a recovery permit
3. Alice Karl has an existing recovery permit, but she will need to amend it to cover work at NextEra Mcoy. Her current permit only allow her to search for lost tortoises with transmittters from a previous study and to remove those transmitters.

DEPARTMENT OF THE ARMY
HEADQUARTERS, UNITED STATES ARMY GARRISON
FORT IRWIN, CA 92310-5000

REPLY TO
ATTENTION OF:

IMNT-PWE

25 February 2012

Diane Noda
US Fish and Wildlife Service
Ventura Fish and Wildlife Office
2493 Portola Rd, Ste. B
Ventura, California 93003

SUBJECT: Biological Opinion Annual Reporting

Dear Ms. Noda,

The United States Army Garrison (USAG) Fort Irwin is submitting the attached annual reports per requirements outlined in two active biological opinions. These biological opinions (BO) are:

1. Attachment 1: Reinitiation of Formal Consultation on the Army's Current Mission at the National Training Center, Fort Irwin, California (1-8-95-F-16R).

2. Attachment 2: Proposed Off-Road Vehicle Area, U.S. Anny National Training Center, Fort Irwin, San Bernardino County, California (1-8-00-F-78).

The attached reports provide information in accordance with the reporting requirements outlined in each of the biological opinions. The annual report for BO #8-8-11-F-38R, Proposed Addition to Maneuver Training Lands at Fort Irwin, California, including information required by USFWS Permit TE-102235-5, will be submitted seperately.

Should you have any questions regarding these reports please contact Clarence Everly, Natural Resources Program Manager, at (760) 380-3740, or clarence.a.everly.civ@mail.mil.

Sincerely,

Muhammad A. Bari
Acting Director of Public Works
Fort Irwin, California

Attachment 1

Biological Opinion # 1-8-95-F-16R

Re-initiation of Formal Consultation on the Army's Current Mission at the National Training Center, Fort Irwin, California

a. Abstract

Each Federal agency shall insure that any action authorized, funded, or carried out by such agency is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of habitat of such species which is determined by the Secretary, after consultation, to be critical, unless such agency has been granted an exemption. In fulfilling the requirements of this paragraph each agency shall use the best scientific and commercial data available. Pursuant to submission of a biological assessment identifying the potential effects of military training activities on threatened, endangered and sensitive species, within the original boundaries of Fort Irwin and the National Training Center, the US Fish and Wildlife Service rendered a biological opinion. The Service stated in its opinion that the effects of military training activities described were not likely to jeopardize the continued existence of the desert tortoise or adversely modify critical habitat. The opinion further requires Fort Irwin submit an annual report summarizing:

1. the number of desert tortoises moved by authorized biologists
2. the number of desert tortoises killed or injured providing the specific information for each tortoise described in term and condition 12 of the opinion
3. any new ITAM program data
4. recommendations for modifying the terms and conditions to enhance desert tortoise protection
5. acreage disturbed, if any, below the UTM 90 line

Fort Irwin conducted fifty-six (56) survey and monitoring efforts in support of projects on the installation during the reporting period. As a result of these activities, two (2) live desert tortoises were observed during construction project actions; fourteen (14) potential or suspected tortoise burrows, one (1) caliche cave and one (1) summer pallet were cleared for occupancy of tortoises. Fourteen (14) tortoise skeletal remains were also recorded (unknown cause of mortality).

In 2012 there were a total of 40 (13 live, 27 carcass) incidental desert tortoise observations within the original boundaries of Fort Irwin.

b. Introduction

The National Training Center (NTC) at Fort Irwin is the army's premier Combat Training Center (CTC) training 10 brigade combat teams each year in exercises called rotations. Rotations last from 28 to 35 days each and involve approximately 6,500 soldiers and Department of the Army civilians. Training at Fort Irwin is designed to replicate combat conditions to provide soldiers the skills and experience needed in order to accomplish their assigned tactical missions.

c. Results

Table 1 is a summary listing of all reported live desert tortoise encounters within the original Fort Irwin boundary for calendar year 2012. In addition to recording these observations, DPW Natural Resources biologists, in accordance with term and condition 9 of the biological opinion, marked three (3) previously un-marked tortoises encountered within the original boundaries of Ft Irwin using a uniquely numbered Floy tag. The purpose of this program is to allow for a passive system of monitoring Fort Irwin tortoises encountered by personnel throughout the installation. ID numbers of animals thus marked are included in Table 1. A total of seventeen (17) tortoises have been tagged since the program's inception in spring of 2010. Since tagging began, no tortoises tagged under this program have been sighted again in the training area.

In 2012, there were a total of forty (40) incidental observations of desert tortoises within the original boundaries of Fort Irwin as reported to DPW (see Figure 1). Thirteen (13) of these observations were of live tortoises. Of the live sightings, eight (8) involved observation of a desert tortoise with no further action taken. Five (5) incidents involved relocating a desert tortoise out of harm's way. Three of these tortoises were tagged with a uniquely-numbered Floy tag. One non-desert tortoise incident involved the capture of an escaped pet Russian tortoise (*Agrionemys horsfieldii*) recovered near the housing area on garrison. This animal tested sero-positive for *Mycoplasma agassizii* and was transferred to Dr. Kristin Berry of USGS Riverside, for further testing. Results of testing on this individual will be included in the CY 2013 report.

09/05	549220	3907220	unk / unk	None noted	Walking	none
09/12	534988	3890755	Adult/ male	NTC1176	Walking to burrow	relocated

Of the forty (40) incidental observations of desert tortoises twenty-seven (27) involved the discovery of tortoise skeletal remains. The increased number of desert tortoise carcasses reported this year (27) over past years is due, in part, to increased cooperation with UXO-removal contractors on Fort Irwin. Field personnel understand the importance of their reporting all tortoise observations, live and dead, during the course of carrying out their regular duties. Additionally, surveys for a proposed alternative energy project by the Fort Irwin main gate resulted in discovery of 13 desert tortoise skeletal remains. A summary of desert tortoise carcasses/skeletal remains found is provided in Table 2 below. Time since death, when provided, was estimated using methods discussed in the proceedings from a workshop on tortoise shell – skeletal remains conducted by Dr. Kirstin Berry (Berry 2002). Of the two most recently-deceased animals, one showed evidence of having drowned in a wash during late summer precipitation events and the second is potentially due to vehicle strike or other major trauma which caused complete separation of the anterior portion of the body.

Table 2. Desert tortoise carcasses recorded on Fort Irwin in 2012.

10/25	532523	3890438	> 4 years	None noted	Severe trauma to plastron – possible vehicle strike

Summary of 2012 Survey and Monitoring Efforts within the original boundaries of Fort Irwin

Table 3, below, presents a consecutive summary of all 2012 construction-related tortoise survey and monitoring efforts conducted within the original boundaries of Fort Irwin. All construction-related survey and monitoring efforts for the year resulted in two (2) live tortoise encounters. Fourteen (14) potential tortoise burrows were identified and cleared of any occupancy by tortoises. Fourteen (14) tortoise skeletal remains consisting of disarticulated bone were observed. Based on the condition of the skeletal remains, time since death and cause of death could not be determined.

d. New ITAM Program Data

There is no new ITAM program data to report at this time.

e. Recommendations

We have no recommendations or modifications to suggest at this time to improve or enhance desert tortoise protection.

f. Acres disturbed below the UTM 90 line

One-hundred-twenty-two kilometers (249 acres) of unauthorized tactical vehicle track were documented below the 90 Gridline in the SEA in late January/early February of the reporting year. Fifteen (15) burrows identified as potential tortoise burrows were impacted; four incidents of other tortoise sign, including fecal scat and carcasses (incl. in Table 2), were also recorded in the impacted area. No live tortoises were found to be injured or killed as a result of this disturbance (US Army 2012). As of April, 2012 the portion of the Southern Expansion Area (SEA) below the 90 Grid Line was opened to military training activities. All remaining tortoises that were identified for translocation have been transferred to a USGS disease research facility (known as the Western Expansion Disease Enclosure or WEDE) in the Western Expansion Area of Fort Irwin.

Attachment 2

Biological Opinion # 1-8-00-F-78

Proposed Off-Road Vehicle Area, U.S. Army National Training Center, Fort Irwin, San Bernardino County, California

INTRODUCTION

Fort Irwin established an ORV Area for military personnel and their dependents to use in their leisure time. There was no authorized area for this type of activity on Fort Irwin. As a result, some soldiers and/or their dependents used various areas of the installation for ORV activity. The availability of a single, officially sanctioned location for ORV use will ensure that other areas of the installation are not further damaged by this type of activity, thereby protecting the desert tortoise and other sensitive species. The established ORV Area is the only authorized area on post upon which this activity is allowed. Established in 2003, the ORV area encompasses approximately 70 acres. It is completely enclosed by triple strand smooth wire and tortoise proof fencing.

Pursuant to a review of the current status of the desert tortoise, the environmental baseline for the action area, the effects of the proposed Outdoor Recreation Vehicle (ORV) Area and cumulative effects, the US Fish and Wildlife Service rendered a biological opinion. The Service stated in its opinion that the ORV Area, as proposed, is not likely to jeopardize the continued existence of the desert tortoise. The opinion further requires Fort Irwin submit an annual report summarizing:

1. Compliance with NTC and Fort Irwin Regulation 350-3 detailing the amount of use occurring at the ORV Area
2. Types and occurrences of violations, such as breaches of the perimeter fence
3. Corrective measures taken to prevent further violations if any occurred

RESULTS

The Fort Irwin OHV area has been closed since October, 2011 due to a lack of maintenance funding. Fort Irwin has no current plans to re-open the facility at this time. There were no patrons to report and zero days of operation resulting in no reports of desert tortoise encounters within the boundaries of the OHV area.

Tortoise fencing surrounding the facility was inspected quarterly. There were no breaches of the OHV area perimeter fence found during the year. No violations of the NTC and Fort Irwin Regulation 350-3 were reported or observed.

Subject: Biological Opinion for the Operations and Activities at Fort Irwin, California

Dear ~~Mr. Bari~~Colonel Braga:

This document transmits the U.S. Fish and Wildlife Service's (Service) biological opinion regarding the effects on the federally threatened desert tortoise (*Gopherus agassizii*) and its critical habitat, in accordance with section 7 of the Endangered Species Act (Act) of 1973, as amended (16 U.S.C. 1531 et seq.), ~~of~~for all identified existing and future similar actions that are likely to occur on Fort Irwin. This document also describes the criteria by which the U.S. Army will determine whether its actions are likely to adversely affect the desert tortoise or its critical habitat and our concurrence with actions that are undertaken within the framework of these criteria.

Comment [c1]: Recommend deleting the word "similar". "Similar" used with the phrase "likely to occur" appears redundant at best or implies a limitation on the projects contemplated in the consultation and that limitation is unclear.

This biological opinion is based on information in our files and discussions with your staff during the course of consultation. A complete record of this consultation can be made available at the Ventura Fish and Wildlife Office.

Consultation History

In response to a request for formal consultation from the Army, dated November 14, 201~~4~~3, for the construction and operation of a solar facility, staff from the Army and Service discussed the basic concepts of this base-wide consultation. The Army and Service agreed to consult formally on future base-wide operations and activities rather than the single solar project. Based on these discussions and our general knowledge of the activities at Fort Irwin from past consultations, we provided a draft biological opinion to the Army. This final biological opinion incorporates the Army's comments on the draft biological opinion.

The Service and Army are aware of only one other federally listed species within the boundaries of Fort Irwin, the endangered Lane Mountain milk-vetch (*Astragalus jaegerianus*). Because of the extremely limited distribution of this species, the Army and Service agreed that we would not include this species in this programmatic consultation. Instead, the Army will manage the Lane Mountain milk-vetch according to the provisions of its integrated natural resources management plan and consult with the Service on a case-by-case basis if any future activity may affect this species. The Army developed the following conservation measures for the Lane Mountain milk-

vetch ~~as~~ during consultation on the use of additional training lands at Fort Irwin.

The Army will ensure the long term survival of the Lane Mountain milk-vetch by:

1. Maintaining the National Training Center - Gemini Conservation Area adjacent to the southern boundary of the Goldstone Deep Space Communications Complex. This 2,471-acre Off-Limits area was fenced in 2003, restricting most vehicle traffic. Most of this population of the Lane Mountain milk-vetch is contained within this conservation area.

2. Maintaining the 4,300-acre East Paradise Conservation Area. This conservation area contains 80 percent of the East Paradise population of the Lane Mountain milk-vetch.

3. Maintaining the 3,700-acre Brinkman Wash Restricted Access Area that contains 1,872 acres of Lane Mountain milk-vetch habitat.

4. Erecting and maintaining signs along the perimeter of the Restricted Access Area at approximately 100 meter intervals and by erecting restricted access signs along all routes that access the Brinkman Wash Restricted Access Area.

5. Incorporating information regarding the off-limits areas into environmental awareness briefings.

6. Delineating all Lane Mountain milk-vetch conservation areas on all training maps.

7. Prohibiting and eliminating all vehicular travel in Lane Mountain milk-vetch conservation areas with the following exceptions: (1) access for yearly monitoring and research approved by the Fort Irwin Natural Resources Program Manager; (2) emergency vehicles, particularly those needed for wildfire control; (3) exceptional natural resource activities, such as feral burro roundups or cultural surveys, approved by the Fort Irwin Natural Resources Program Manager.

8. Utilizing observer/controller teams to prevent unnecessary habitat destruction by rotational units unfamiliar with the terrain and travel routes.

9. Identifying and conserving potential habitat for the Lane Mountain milk-vetch within the region. Fort Irwin will:

   - Identify and survey for small pockets of potential habitat, defined by soil, bedrock geology, and elevation, found within the boundaries of Fort Irwin.

   - If potential habitat for the Lane Mountain milkvetch is found, attempt to reduce training in the area by reclassifying the area as “No Dig.” If reclassification is possible and does not limit the Army’s mission, the Army will erect signs and siebert stakes around the periphery of the area and notify Integrated Training Area

Management GIS so that the reclassification will appear on the next update of the range map.

10. Conserving host plants and using the viability of host plants as an indicator of ecosystem health in Lane Mountain milk-vetch habitat.

11. To ~~prevent~~monitor impacts to the Lane Mountain milk-vetch from fugitive dust, erect passive dust monitoring stations so that dust deposition can be monitored.

12. Appling soil binders to main supply routes and battalion staging areas to reduce dust production.

13. Monitoring and controlling invasive plants and weeds and monitoring and mapping the spread of exotic species in Lane Mountain milk-vetch habitat.

ADMINISTRATION OF THE CONSULTATION

The Army will evaluate future actions that may affect the desert tortoise or its critical habitat at Fort Irwin ~~in the following manner~~. The Natural and Cultural Resources Program Manager of the Directorate of Public Works at Fort Irwin will review all discretionary actions that the Army proposes on Fort Irwin. Based on the nature of the activity, its potential to adversely affect desert tortoises or their critical habitat, and any measures that can be implemented to avoid or minimize the effect, the Army will determine whether the action will not affect, is not likely to adversely affect, or is likely to adversely affect the desert tortoise or its critical habitat.

The Army will maintain a record of all its activities that undergo this evaluation. For actions that do not affect or are not likely to adversely affect the desert tortoise or its critical habitat, the Army will include in its record:

1. The title of the action;
2. A description of the proposed action;
3. Location;
4. Size; and
5. The rationale that it used to reach its determination regarding effects to the desert tortoise or its critical habitat.

For actions that are likely to adversely affect the desert tortoise or its critical habitat, the Army will include in its record:

1. The title of the proposed action;
2. A description of the proposed action;
3. Location;
4. Size;
5. The number of desert tortoises that are killed, injured, and moved from harm's way;
6. The amount of habitat disturbed or lost, with a notation as to whether the affected area was designated critical habitat;
7. A list~~ed~~ of authorized biologists who worked on actions covered by this consultation in the reporting year; and

8. A brief but comprehensive discussion of the protective measures used and whether the protective measures were effective. If the measures were not effective, the Army will explain why the measures did not function as expected and recommendations for implementing more effective measures.

In past consultations with the Army, the Service has authorized biologists to implement protective measures and handle desert tortoises on a project-by-project basis. Upon completion of this consultation, the Army will not request such authorization on a project-by-project basis. From this point, any person ~~that is~~ approved by the Service to undertake the duties of an authorized biologist for Army actions may also perform those duties on future Army actions if those actions are within the scope of~~proposed by the Army that are covered by~~ this biological opinion~~ may also perform those duties on future actions~~. If the Army determines that an authorized biologist is not performing his or her duties in a satisfactory manner, the Army will notify the Service at the earliest possible time it makes this determination.

The Service and Army agree ~~that some~~ actions ~~may be~~ proposed in the future ~~that~~ may result in effects which may be beyond the scope of those considered in this biological opinion. In the case of such actions, the Army and Service will ~~discuss~~determine whether this biological opinion sufficiently considered the proposed actions's effects to the desert tortoise and its critical habitat ~~in light of the proposed action~~ and whether re-initiation of formal consultation or initiation of a separate consultation is appropriate.

If staff from the Service and Army cannot agree on a course of action after discussions on this or other issues, any disagreement will be elevated to the Palm Springs Fish and Wildlife Office's Deputy Assistant Field Supervisor and the Army's Natural and Cultural Resources Program Manager for resolution. If further elevation is required, the Assistant Field Supervisor of the Palm Springs Fish and Wildlife Office and the Director of Public Works at Fort Irwin will be contacted to resolve the issue. Although the elevation of issues is likely to be an infrequent occurrence, the Army and Service consider this procedure to be a useful tool to maintain efficient processes and a healthy working relationship between our agencies.

The Army will provide the Service with an annual report of the activities that it conducts under the auspices of this consultation. The annual report will include the information that the Army will maintain in its records for any activity it determined was likely to adversely affect the desert tortoise or its critical habitat, as described in this section. The annual report will be provided to the Service by January 31 of each year this biological opinion is in effect.

Comment [c2]: What is the term of this biological opinion? Do we need one given that we will essentially meet and review the document annually?

The annual report will also contain information on conservation activities that the Army undertook in the previous year. Such activities may include, but are not limited to, acquisition of land through the Readiness and Environmental Preparedness Initiative and results of research on desert tortoises conducted or funded by the Army. In some cases, such as when the Army funds range-wide sampling of the desert tortoise, the Army would not provide the results of the work because the Service would summarize these findings in its annual reporting on the sampling effort.

The Palm Springs Fish and Wildlife Office's Deputy Assistant Field Supervisor and the Army's

Natural and Cultural Resources Program Manager, and appropriate staff, will meet annually to review how this consultation is functioning and to discuss any potentially important events in the upcoming year. If the Service and Army agree that such a meeting is unnecessary in any given year, the meeting may be cancelled.

Criteria for Use in Reaching Appropriate Determinations

The Army will use the following ~~outline~~protocol to determine the appropriate level of consultation required for each proposed action.

1. Projects in which any effects would occur outside of desert tortoise habitat would have no effect on the species; the Army will document its determinations in these situations for its own records but would not need to contact the Service. If the Army requires technical assistance from the Service to determine if suitable habitat for desert tortoises would be affected, it will contact us by phone or electronic mail.

2. If the following criteria are met, a determination of not likely to adversely affect the desert tortoise would be appropriate:

   a. The project is within habitat of the desert tortoise;

   b. Desert tortoise habitat is present, but degraded or disturbed, in the project area. For the purposes of this consultation, the Army and Service consider degraded habitat to be ~~that~~ habitat which has been affected by previous activities. Degraded habitat will generally exhibit a lower diversity and density of native shrubs and disrupted substrates than undisturbed habitat. The Army and Service ~~may~~ consider certain washes to be disturbed habitat; the fundamental characteristic for~~guidance in~~ such areas is ~~that~~ the evidence of the project activity would no longer be visible after an event where water flows in the wash. The loss or disturbance of a minor amount of undisturbed habitat may also be considered as being not likely to adversely affect the species, when considered with regard to its distribution in the action area; and

   c. Neither desert tortoises nor their diagnostic sign are observed during surveys or a habitat assessment.

   d. I~~n~~f the Army concludes a determination of adverse impact to the desert tortoise is not clear, then ~~cases where a determination is not entirely clear from a verbal description,~~ the Army will provide a verbal description of the habitat and appropriate photographs of the project site to the Service ~~with a photograph (aerial or otherwise, as appropriate) of the project site to~~which will assist in ~~its~~the determination.

3. If the following criteria are met, a determination of not likely to adversely modify or destroy~~affect~~ critical habitat for the desert tortoise w~~ould~~ill be appropriate:

   a. The project is within designated critical habitat, but the primary constituent elements of desert tortoise critical habitat are not present;

b. The primary constituent elements would not be affected by the proposed project; or

c. Effects to the primary constituent elements would be so minor that they are not measurable when considered within the context of the critical habitat unit. Such effects may occur, for example, when a narrow strip of land supporting the primary constituent elements of critical habitat at the edge of an existing road may be affected by an action.

BIOLOGICAL OPINION

DESCRIPTION OF THE PROPOSED ACTION

Unless otherwise noted, the information in this section is from the integrated natural resources management plan for Fort Irwin (Army 2006 - 2011). The mission of Fort Irwin is to provide tough, realistic training for Army brigade combat teams under full battle conditions. Fort Irwin's battlefield is large and instrumented to record training activities; the instrumentation allows the Army to provide continuous and real-time feedback and heighten learning at all levels. Fort Irwin also serves as a laboratory and data source for training, doctrine, organization, and equipment.

Training on maneuver lands includes brigade-level force-on-force training and other operations that occur on a more limited scale. Brigade-level training generally involves 3,000 to 5,000 soldiers and 1,400 vehicles during an exercise. Force-on-force training is the movement of soldiers and equipment over the battlefield in realistic training exercises.

The Army also develops and operates training sites that specifically address military operations in urban terrain. These sites, which can vary in size from 500 meters by 500 meters to 4 square kilometers depending on their use and number of facilities to be replicated, simulate urban combat environments in which soldiers may find themselves worldwide; they provide soldiers the opportunity for combat training in realistic urbanized environments. Training may involve numerous soldiers and role players living at some facilities for up to ~~2 weeks~~18 days at a time.

Comment [c3]: The Army will experiment with an 18 day rotation in Jan, 2015. If it goes well, they may go to that model permanently. If they do, the number of rotations annually may be reduced to 8. Not sure how this will work yet.

All of the activities on Fort Irwin require the Army to continually maintain and upgrade its infrastructure. It also implements numerous activities that are related to overall management of the installation. The Army generally divided these activities into five categories (Everly 2014).

Training Area Activities

These activities include: monitoring and maintenance of improvised explosive device training culverts; deconstruction/relocation of existing training villages; construction of new training villages; deconstruction of existing forward operating bases (removal of concrete slabs, removal of command and control buildings, leveling of protective berms, removal of HESCO barriers [HESCO barriers are large wire and canvas containers that units can fill with soil that are used to provide cover]); construction of forward operating bases to include building protective berms, installing HESCO barriers, pouring concrete pads for tents, and construction of small command and control facilities; installation of trench complexes serving as defensive positions, obstacles

for breach training activities, and gap crossing exercises; construction/refurbishment of helipads (compacted dirt/gravel or poured concrete); construction/refurbishment of forward arming and refuel points (compacted dirt/gravel or poured concrete); building/refurbishing unmanned aerial vehicle runways (compacted dirt/paved); refurbishing Goldstone Airfield to include realignment of Goddard Road, construction of a hangar facility and related infrastructure (utilities, fiber); building/refurbishing flight landing strips (compacted dirt) for use in conducting forced entry and ~~lodgement~~ airfield seizure and lodgement expansion operations. ~~The c~~Construction of flight landing strips will include a mock tower, mock fuel storage facility, taxiway, aircraft parking area, and temporary aircraft refueling pad. All of these activities involve the use of heavy construction equipment (bulldozers, graders, dump trucks) to clear and compact dirt in the construction footprint. Access to the construction sites will be by existing dirt/paved roads. Drop zone areas, in proximity to the flight landing strip locations, may also be designated. While drop zones normally require no construction activities they are areas used for parachutists to land in as well as for dropping equipment and supplies, by parachute, for use by soldiers delivered to the battlefield by parachute. Impacts to designated drop zone lands result from the landing of parachutists and their equipment.

Training Area Management/Safety Activities

These activities include: maneuver trail improvement and maintenance involving the re-contouring of existing trails, installation of gabions and rolling ditches and repair of existing dirt trails as a result of use/erosion events; monitoring and maintenance of erosion control culverts; application of dust suppressants on dirt trails (soil cement/magnesium chloride) on Fort Irwin and the Manix Trail right-of-way; closing of existing dirt trails; development of new trail networks; installation of communication sites consisting of antennae construction (including a concrete pad) or refurbishment of an existing structure, installation of communication equipment cabinets, installation of power generation equipment/hardwire sites in from existing utility lines; installation of fiber optic lines and associated equipment vaults; habitat restoration to include mechanical/hand seeding and emplacement of native plant seedlings; move/add/replace targets to include digging of target pits to house target lifting mechanisms; building, upgrading, maintaining combat training ranges (small arms ranges, hand grenade range, urban assault range) including building/replacing backstop berms, digging fighting positions, digging up/replacing/emplacing new electrical wiring and fiber, emplacing new target lifting mechanisms, repairing/replacing/installing new range towers, emplacing safety markers, building shoot houses and urban obstacles/targets. All of these activities involve the use of heavy construction equipment (bulldozers, graders, backhoes, dump trucks) to clear and compact dirt in the construction footprint. Access to the construction sites will be by existing dirt/paved roads.

Cantonment Infrastructure Activities

These activities include: utilities (water, sewer, gas, electric) maintenance, repair, replacement and installation of new lines and associated structures (water tanks, transformers, LPG tanks, etc.); destruction/removal of existing facilities; maintenance, repair, replacement, and/or construction of new facilities (barracks, hospital, housing, water treatment plant, company operations facilities, aircraft hangars, warehouses, maintenance buildings, office buildings, headquarters buildings, etc.); activation of new units to include construction/renovation/repair of

related housing, office, maintenance and training facilities; deactivation of existing units to include destruction/removal of facilities no longer needed and the repair/renovation of associated housing, office, maintenance and training facilities; construction, repair and maintenance of roads and related structures (culverts, bridges, overpasses, etc.); fence installation, maintenance, and repair; and sign installation, maintenance and repair.

Alternative Energy Activities

These activities include: construction, operation and maintenance of solar energy sites within the boundaries of Fort Irwin (includes grading/ leveling of the site, installation of solar technology, trenching for laying of electrical wire, installation of associated infrastructure, interconnection to existing electrical transmission capabilities, etc.); construction of shade structures with attached solar technology and related electrical connection infrastructure; and construction of a waste-to-energy facility including excavation of materials from the existing landfill, modification to existing baler/solid waste receiving facilities, and construction of a pyrolytic conversion facility (building, concrete pad, utilities) for conversion of solid waste to electrical energy~~;~~.

Comment [c4]: Ray, Should we include development of wind energy sites as well? We will not currently erect any because of the effects to aircraft training and testing in the R2508. However, if technology changes such that no effects from wind turbines exist to military AC systems it may be something we would want to investigate.

Recreation and Related Activities

These activities include: Hunting of state authorized game species, planning, constructing (identifying the course route, digging pits to be filled with water, creating dirt mounds over which contestants must rung, etc.) and deconstructing "mud run" courses, conducting tours of old mining towns and historic sites utilizing off road capable buses (tours will utilize existing roads and trails), off highway vehicle use following designated routes, and construction, operation and deconstruction of a paint ball course. Rock hounding in designated areas, camping in designated areas, construction, operation, maintenance and deconstruction of athletic fields and playground sites (in cantonment), and the erection, use and tear down of tents, portable generators, trailers, booths, etc. for use during holiday celebrations (in cantonment).

Research and Education Activities

These activities include: sensitive species inventory, survey and monitoring (includes access by existing roads to survey/monitoring sites; surveys/monitoring will be conducted on foot or by vehicle driven at very low speeds); digging, fence installation, burning, trimming, seeding, equipment installation (cameras, weather stations, etc.) in support of research projects; off limits area fence installation, maintenance, and repair; Siebert stake installation, maintenance and repair; off limits area sign installation, maintenance and repair; fire management in off limits areas (respond to wildfires); and feral burro removal.

Comment [c5]: I was reminded that we conduct portions of our burrowing owl surveys by vehicle using existing roads and trails.

The Army will also undertake numerous actions in the course of managing natural resources on Fort Irwin. These measures include but are not limited to:

1. Continuing the control of invasive species to reduce degradation of plant and wildlife habitats on Fort Irwin.

2. Continuing control of feral burros on Fort Irwin to better protect natural resources.

3. Undertaking surveys of project sites and buffers that may affect desert tortoises to document plant and animal species.

4. Conducting post-project monitoring of certain activities that have the potential to affect federally listed species. The purpose of this monitoring is to ensure that avoidance and minimization measures have been properly implemented, to assess the effectiveness of these measures, and to allow for modifications to minimization measures, as needed.

Protective Measures

The Army will continue to implement procedures designed to minimize impacts to desert tortoises. These procedures will ensure that potential impacts are minimized ~~as much as possible~~ by being assessed during the project planning and approval process and monitored for compliance and effectiveness.

1. The Army will minimize incidental injury and mortality of desert tortoises by employing the following measures. Actual measures will be based on the results of site-specific field surveys and will be implemented, as needed, at the ~~discretion~~professional judgement of the Army's environmental personnel (hereafter 'environmental staff'), including:

   a. Clearly delineating the boundaries of new construction or new target and test sites on the ground by flagging, survey lath, or wooden stakes;

   b. Placing signs, as needed, to indicate the need to reduce speeds on roadways and that activities are to be strictly confined to the project site;

   c. Biological monitoring of operations involved with the active removal of desert tortoise habitat known to be near the project site. Activities within existing test and target operations (operations including area preparation, target set-up, the actual test event and the target removal and site clean-up) would not require biological monitoring. The purpose of the biological monitoring is to ensure that avoidance and minimization measures have been properly implemented, to assess the effectiveness of these measures and to allow for modifications to minimization measures, as needed.

   d. Placing desert tortoise-proof fences around projects or portions of projects in desert tortoise habitat where~~,~~ the probability of injuring or killing a desert tortoise, without such fencing in place, is considered to be reasonably foreseeable.

2. Desert tortoise burrows located within 100 feet of the limits of construction or establishment of new target or test site boundaries will be protected by conducting additional on-site project personnel briefings (tailgate). If necessary, the Army will either (1) place temporary (short-term) desert tortoise-proof fencing to completely enclose the burrow at a minimum distance of 20 feet from the burrow or, (2) for longer duration construction projects, fence the limits of construction to avoid any potential impacts to desert tortoises.

Comment [c6]: I would like to use a qualifying term here so that someone in the future cannot argue that FWS is giving blanket discretion to the Army's environmental staff.

3. Desert tortoise burrows that cannot be avoided will be excavated by hand either by or under the direct supervision of an authorized biologist. Burrow excavation and subsequent handling of any desert tortoises will follow the most up-to-date guidelines that are acceptable to the Service.

4. The Army will submit the credentials of personnel to be designated as authorized biologists to the Service at least 30 days prior to the onset of the activities to be monitored. The general qualifications and the request form are located on the Ventura Fish and Wildlife Office's website at http://www.fws.gov/ventura/species_information/protocols_guidelines/index.html.

5. All trash and debris will be promptly contained within containers that common ravens (*Corvus corax*) cannot access. These containers will be regularly removed from project sites to reduce the attractiveness of the area to common ravens and other desert tortoise predators.

6. Environmental staff will conduct awareness briefings for all personnel working in desert tortoise habitat. These briefings will be conducted either in person or via a video presentation of the briefing. At a minimum, the briefings will include discussions of:

   a. the general provisions of the Endangered Species Act;

   b. the necessity for adhering to the provisions of the Act~~, including both civil and criminal penalties for noncompliance. The penalties for these violations can be a maximum fine of up to $50,000 or imprisonment for one year, or both, and civil penalties of up to $25,000 per violation, may be assessed;~~

   c. the potential for civil and criminal penalties associated with violating the provisions of the Act;

   d. the specific requirements for complying with the provisions of the Act as they relate to each project;

   e. the exact boundaries of the site within which the project activities may be accomplished;

   f. the procedures to be accomplished by project personnel should any problem arise with respect to complying with environmental requirements~~constraints~~;

   g. general behavior and ecology of the desert tortoise and its sensitivity to human activities;

   h. all personnel will be advised of the potential for desert tortoises to take refuge under vehicles and of the proper procedures to follow in that event; and

   i. specific procedures to be followed to move a desert tortoise that may be in imminent danger (on a heavily traveled road, on an active project site, or under a vehicle).

7. All personnel will check beneath their vehicles while in desert tortoise habitat prior to moving the vehicle. If a desert tortoise is found beneath the vehicle, it will be moved by environmental staff or by project personnel in accordance with guidelines provided to them during the awareness briefings. ~~All personnel will be advised of the potential for desert tortoises to take refuge under vehicles and of the proper procedures to follow in that event.~~ The Army will report any removals of desert tortoises to the Service in its annual report.

Comment [c7]: Already stated in h. above.

8. The primary means to eliminate or minimize impacts to desert tortoises or their habitat will continue to be implemented through the use of avoidance and minimization procedures. These methods include the following:

    a. To the extent possible, project sites will be selected so that they are located in previously disturbed areas.

    b. Surveys for desert tortoises will be accomplished for any project that occurs in potential habitat. Surveys will be conducted to support the analysis conducted under the National Environmental Policy Act for new surface disturbing projects and where new disturbance may occur in desert tortoise habitat. Biologists will conduct surveys in accordance with the most current Service survey guidelines., ~~except s~~Surveys may be conducted year-round due to the short timelines associated with the Army's activities.

    c. If new projects are located in desert tortoise habitat, environmental staff will, in conjunction with project proponents, attempt to reduce impacts by assessing the feasibility of adjusting a project's size, footprint, orientation, and construction method;

    d. If new projects ~~have to~~will be located where desert tortoises are known to occupy the project site, desert tortoises will be relocated by Service-authorized biologists prior to start of any activities. Authorized biologists are responsible for adhering to Service protocols and guidelines for handling and relocating desert tortoises.

    e. New land-disturbing activities that have occurred within habitats that support desert tortoises will continue to be documented in annual reports submitted to the Service.

9. The Army will maintain coordination with Service and fulfill annual reporting requirements.

Management of Common Ravens

The integrated natural resources management plan (Army 2006 – 2011) for Fort Irwin notes that the Army will alter landfills and sewage ponds to reduce the number of predators (including common ravens) that use these sites. The Army will also implement predator control programs and participate in regional plans sponsored by the Desert Managers Group to control common ravens. As a standard practice, the Army requires soldiers and contractors to bag and dispose of all trash and food items generated by training, construction, and maintenance activities.

Relocation of Desert Tortoises

In the event that future development or activities would result in the clearing of suitable desert tortoise habitat, the Army would relocate desert tortoises from these sites to other habitat. Depending on the type of development and its location, desert tortoises may be moved to suitable habitat immediately off-site or to other suitable habitat on the installation where they would be less likely to be affected by the Army's activities; the Army may move desert tortoises to a conservation area if it provides the best fit. The authorized biologist and Natural Resources Program Manager will determine the appropriate locations. The authorized biologist will examine all desert tortoises that are moved away from the site of their capture for clinical signs of disease prior to moving them. If a desert tortoise exhibits clinical signs of disease, in consultation with the Service it will either be moved immediately off site or removed from the wild if the Service determines that is the best course of action.

On occasions when desert tortoises may be at risk of being injured or killed by other types of activities (e.g., it is on or near a road), the Army will assess the situation and implement the most appropriate measure. The Fort Irwin Natural Resources Program Manager or the unit's Environmental Compliance Team personnel will choose from a suite of measures depending on the circumstances. For example, if a desert tortoise is in a road and blocking a few vehicles, the drivers will avoid the desert tortoise by driving around it. If the desert tortoise is on a road that will be used throughout the day, the Army will notify other units in the area and may assign someone to monitor the desert tortoise. In some cases, the Army may be familiar with the animal's b~~o~~urrow(s) and use of the area and may move it out of danger into areas it frequents.

Extent of Future Development

The Environmental Baseline – Previous Consultations in the Action Area section of this biological opinion describes the previous biological opinions that addressed the Army's training activities at Fort Irwin (Service 1991a, 2012). In these biological opinions, we analyzed the effects of the Army's various training activities on the desert tortoise and its critical habitat throughout Fort Irwin, with the exception of the western expansion area. (We describe the current situation in the western expansion area in the Environmental Baseline – Previous Consultations in the Action Area section of this biological opinion.) Consequently, because we have already conducted these analyses, this biological opinion addresses only the development of new infrastructure at Fort Irwin and the operation and maintenance of new and existing infrastructure.

Comment [c8]: Recommend clarifying. This section is more a discussion of the history of consultations rather than a discussion of the Environmental Baseline. If the idea is to incorporate by reference the discussion of the Environmental Baseline from prior BiOPs, then recommend inserting a sentence or two into this document. One sentence would incorporate the prior BiOPs and the second would say the prior discuss is current.

Comment [c9]: Can different terms be used as a substitute for "The Environmental Baseline"? The use here is confusing as it creates the expectation a discussion of the environmental baseline will follow. The actual Environmental Baseline seems to start on page 32 of the document.

To ensure that its activities do not result in numerous injuries to or mortalities of desert tortoises, the Army has proposed to examine any incident that results in injury or mortality and determine whether additional protective measures are needed to reduce the potential for future injury or mortality. The Army may informally consult with the Service regarding the need for or nature of additional measures if it so chooses. The Army has also proposed to re-initiate formal consultation if five desert tortoises are killed or injured in a calendar year as a result of the actions considered in this biological opinion.

Past training activities at Fort Irwin have disturbed most areas within the valley bottoms and lower alluvial fans within the installation's original~~former~~ boundary; the Service's (2012)

biological opinion on the use of additional training lands in the Eastgate parcel and the southern expansion area considered the effects of training on habitat, including critical habitat, in these areas. In combination, these biological opinions recognized that training activities, including force-on-force maneuvers and the construction and operation of training sites for military operations in urban terrain, have either already removed (in the case of the area within the ~~former~~original boundary) or would eventually remove most habitat value from training areas. Additionally, we recognize that, even considering the future development of solar fields at Fort Irwin, the development of new infrastructure would be a minor fraction of the area that would be affected by training; consequently, the Army and Service agreed that we would not include a threshold for re-initiation of formal consultation in this document that addressed the disturbance of habitat in general or critical habitat.

ANALYTICAL FRAMEWORK FOR THE JEOPARDY AND ADVERSE MODIFICATION DETERMINATIONS

Jeopardy Determination

Section 7(a)(2) of the Endangered Species Act requires that Federal agencies ensure that any action they authorize, fund, or carry out is not likely to jeopardize the continued existence of listed species. "Jeopardize the continued existence of" means to engage in an action that reasonably would be expected, directly or indirectly, to reduce appreciably the likelihood of both the survival and recovery of a listed species in the wild by reducing the reproduction, numbers, or distribution of that species (50 Code of Federal Regulations 402.02).

The jeopardy analysis in this biological opinion relies on four components: (1) the status of the species, which describes the range-wide condition of the desert tortoise, the factors responsible for that condition, and its survival and recovery needs; (2) the environmental baseline, which analyzes the condition of the desert tortoise in the action area, the factors responsible for that condition, and the relationship of the action area to the survival and recovery of the desert tortoise; (3) the effects of the action, which determine the direct and indirect impacts of the proposed federal action and the effects of any interrelated or interdependent activities on the desert tortoise; and (4) the cumulative effects, which evaluate the effects of future, non-federal activities in the action area on the desert tortoise.

In accordance with policy and regulation, the jeopardy determination is made by evaluating the effects of the proposed federal action in the context of the current status of the desert tortoise, taking into account any cumulative effects, to determine if implementation of the proposed action is likely to cause an appreciable reduction in the likelihood of both the survival and recovery of the desert tortoise in the wild.

Adverse Modification Determination

Section 7(a)(2) of the Endangered Species Act requires that Federal agencies ensure that any action they authorize, fund, or carry out is not likely to result in the destruction or adverse modification of the critical habitat of listed species. This biological opinion does not rely on the regulatory definition of "destruction or adverse modification" of critical habitat at 50 Code of

Federal Regulations 402.02. Instead, we have relied on the statutory provisions of the Act to complete the following analysis with respect to critical habitat.

In accordance with policy and regulation, the adverse modification analysis in this biological opinion relies on four components: (1) the status of critical habitat, which describes the range-wide condition of designated critical habitat for the desert tortoise in terms of primary constituent elements, the factors responsible for that condition, and the intended recovery function of the critical habitat overall; (2) the environmental baseline, which analyzes the condition of the critical habitat in the action area, the factors responsible for that condition, and the recovery role of the critical habitat in the action area; (3) the effects of the action, which determines the direct and indirect impacts of the proposed federal action and the effects of any interrelated and interdependent activities on the primary constituent elements and how that will influence the recovery role of the affected critical habitat units; and (4) cumulative effects, which evaluates the effects of future non-federal activities in the action area on the primary constituent elements and how that will influence the recovery role of affected critical habitat units.

Comment [sc10]: If they are relying on the statutory provisions of the Act, then why are they citing policy and regulation – should they not cite the Act?

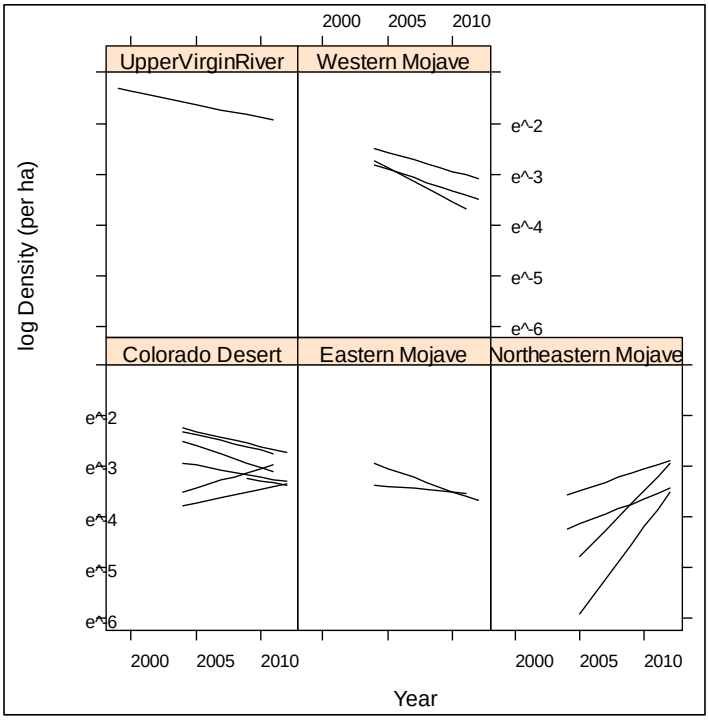
For purposes of the adverse modification determination, the effects of the proposed Federal action on the critical habitat of the desert tortoise are evaluated in the context of the range-wide condition of the critical habitat, taking into account any cumulative effects, to determine if the critical habitat range-wide would remain functional (or would retain the current ability for the primary constituent elements to be functionally established in areas of currently unsuitable but capable habitat) to serve its intended recovery role for the desert tortoise.

STATUS OF THE DESERT TORTOISE AND CRITICAL HABITAT

Status of the Desert Tortoise

Section 4(c)(2) of the Endangered Species Act requires the Service to conduct a status review of each listed species at least once every 5 years. The purpose of a 5-year review is to evaluate whether or not the species' status has changed since it was listed (or since the most recent 5-year review); these reviews, at the time of their completion, provide the most up-to-date information on the range-wide status of the species. For this reason, we are appending the 5-year review of the status of the desert tortoise (Appendix 1; Service 2010e) to this biological opinion and are incorporating it by reference to provide most of the information needed for this section of the biological opinion. The following paragraphs provide a summary of the relevant information in the 5-year review.

In the 5-year review, the Service discusses the status of the desert tortoise as a single distinct population segment and provides information on the Federal Register notices that resulted in its listing and the designation of critical habitat. The Service also describes the desert tortoise's ecology, life history, spatial distribution, abundance, habitats, and the threats that led to its listing (i.e., the 5-factor analysis required by section 4(a)(1) of the Endangered Species Act). In the 5-year review, the Service concluded by recommending that the status of the desert tortoise as a threatened species be maintained.



With regard to the status of the desert tortoise as a distinct population segment, the Service

concluded in the 5-year review that the recovery units recognized in the original and revised recovery plans (Service 1994 and 2011e, respectively) do not qualify as distinct population segments under the Service's distinct population segment policy (61 Federal Register 4722; February 7, 1996). We reached this conclusion because individuals of the listed taxon occupy habitat that is relatively continuously distributed, exhibit genetic differentiation that is consistent with isolation-by-distance in a continuous-distribution model of gene flow, and likely vary in behavioral and physiological characteristics across the area they occupy as a result of the transitional nature of, or environmental gradations between, the described subdivisions of the Mojave and Colorado deserts.

In the 5-year review, the Service summarizes information with regard to the desert tortoise's ecology and life history. Of key importance to assessing threats to the species and to developing and implementing a strategy for recovery is that desert tortoises are long lived, require up to 20 years to reach sexual maturity, and have low reproductive rates during a long period of reproductive potential. The number of eggs that a female desert tortoise can produce in a season is dependent on a variety of factors including environment, habitat, availability of forage and drinking water, and physiological condition. Predation seems to play an important role in clutch failure. Predation and environmental factors also affect the survival of hatchlings.
In the 5-year review, the Service also discusses various means by which researchers have attempted to determine the abundance of desert tortoises and the strengths and weaknesses of those methods. Due to differences in area covered and especially to the non-representative nature of earlier sample sites, data gathered by the Service's current range-wide monitoring program cannot be reliably compared to information gathered through other means at this time.

The Service provides a summary table of the results of range-wide monitoring, initiated in 2001, in the 5-year review. This ongoing sampling effort is the first comprehensive attempt to determine the densities of desert tortoises across their range. Table 1 of the 5-year review provides a summary of data collected from 2001 through 2007; we summarize data from the 2008 through 2012 sampling efforts in subsequent reports (Service 2012a, 2012b, 2012c, 2012d).

The Desert Tortoise Recovery Office (Service 2014) used these annual density estimates to evaluate range-wide trends in the density of desert tortoises over time. This analysis indicates that densities in the Northeastern Mojave Recovery Unit have increased by approximately 13.6 percent per year since 2004, with the rate of increase apparently resulting from increased survival of adults and subadults moving into the adult size class. The analysis also indicates that the populations in the other 4 recovery units are declining: Upper Virgin River (-5.1 percent), Eastern Mojave (-6.0 percent), Western Mojave (-8.6 percent), and Colorado Desert (-3.4 percent; however, densities in the Joshua Tree and Piute Valley conservation areas within this unit seem to be increasing). The following figure shows linear trends in the log-transformed densities in each desert tortoise conservation area by recovery unit. Data for the Upper Virgin River Recovery Unit are from 1999 to the present; data for all other recovery units are from 2004 to the present.

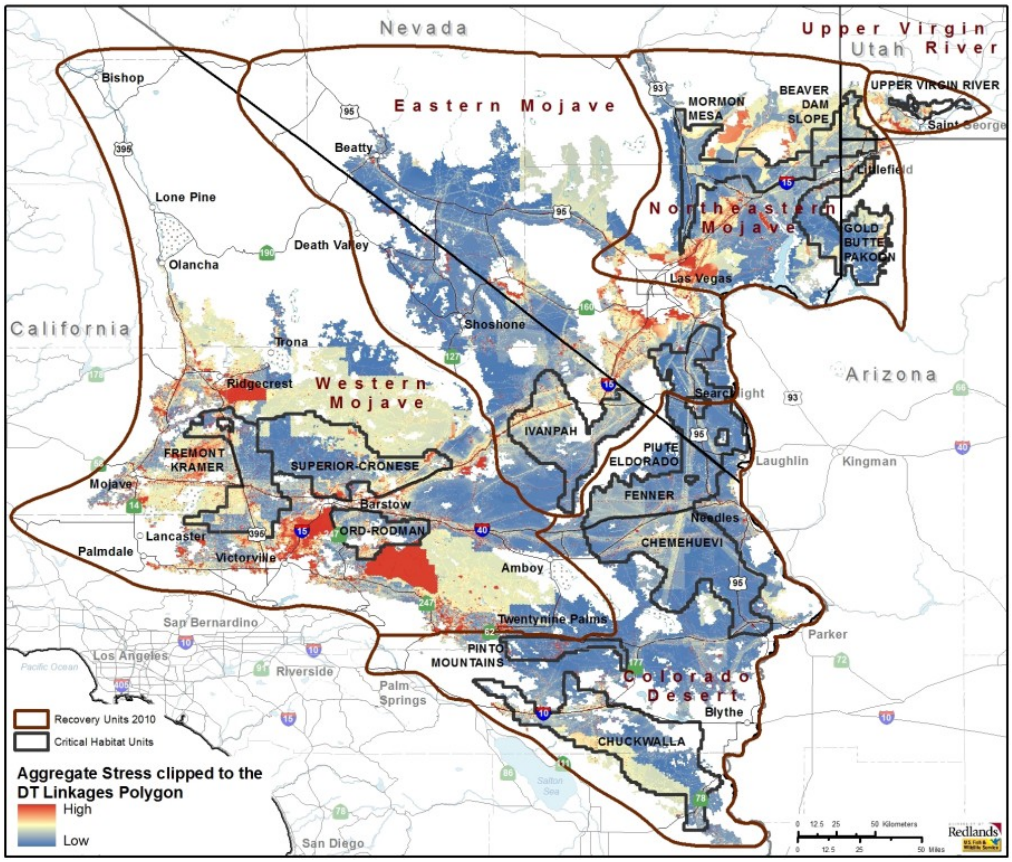
Allison (2014) also evaluated changes in size distribution of desert tortoises since 2001. In the Western Mojave and Colorado Desert recovery units, the relative number of juveniles to adults indicates that juvenile numbers are declining faster than adults. In the Eastern Mojave, the number of juvenile desert tortoises is also declining, but not as rapidly as the number of adults. In the Upper Virgin River Recovery Unit, trends in juvenile numbers are similar to those of adults; in the Northeastern Mojave Recovery Unit, the number of juveniles is increasing, but not as rapidly as are adult numbers in that recovery unit. Juvenile numbers, like adult densities, are responding in a directional way, with increasing, stable, or decreasing trends, depending on the recovery unit where they are~~a~~ found.

In the 5-year review, the Service provides a brief summary of habitat use by desert tortoises; more detailed information is available in the revised recovery plan (Service 2011e). In the absence of specific and recent information on the location of habitable areas of the Mojave Desert, especially at the outer edges of this area, the 5-year review also describes and relies heavily on a quantitative, spatial habitat model for the desert tortoise north and west of the Colorado River that incorporates environmental variables such as precipitation, geology, vegetation, and slope and is based on occurrence data of desert tortoises from sources spanning more than 80 years, including data from the 2001 to 2005 range-wide monitoring surveys (Nussear et al. 2009). The model predicts the probability that desert tortoises will be present in any given location; calculations of the amount of desert tortoise habitat in the 5-year review and in this biological opinion use a threshold of 0.5 or greater predicted value for potential desert

tortoise habitat. The model does not account for anthropogenic effects to habitat and represents the potential for occupancy by desert tortoises absent these effects.

To begin integrating anthropogenic activities and the variable risk levels they bring to different parts of the Mojave and Colorado deserts, the Service completed an extensive review of the threats known to affect desert tortoises at the time of their listing and updated that information with more current findings in the 5-year review. The review follows the format of the five-factor analysis required by section 4(a)(1) of the Endangered Species Act. The Service described these threats as part of the process of its listing (55 Federal Register 12178; April 2, 1990), further discussed them in the original recovery plan (Service 1994), and reviewed them again in the revised recovery plan (Service 2011e).

To understand better the relationship of threats to populations of desert tortoises and the most effective manner to implement recovery actions, the Desert Tortoise Recovery Office is developing a spatial decision support system that models the interrelationships of threats to desert tortoises and how those threats affect population change. The spatial decision support system describes the numerous threats that desert tortoises face, explains how these threats interact to affect individual animals and habitat, and how these effects in turn bring about changes in populations. For example, we have long known that the construction of a transmission line can result in the death of desert tortoises and loss of habitat. We have also known that common ravens, known predators of desert tortoises, use the transmission line's pylons for nesting, roosting, and perching and that the access routes associated with transmission lines provide a vector for the introduction and spread of invasive weeds and facilitate increased human access into an area. Increased human access can accelerate illegal collection and release of desert tortoises and their deliberate maiming and killing, as well as facilitate the spread of other threats associated with human presence, such as vehicle use, garbage and dumping, and invasive plants (Service 2011e). Changes in the abundance of native plants because of invasive weeds can compromise the physiological health of desert tortoises, making them more vulnerable to drought, disease, and predation. The spatial decision support system allows us to map threats across the range of the desert tortoise and model the intensity of stresses that these multiple and combined threats place on desert tortoise populations.



The threats described in the listing rule and both recovery plans continue to affect the species. Indirect impacts to desert tortoise populations and habitat occur in accessible areas that interface with human activity. Most threats to the desert tortoise or its habitat are associated with human land uses; research since 1994 has clarified many mechanisms by which these threats act on desert tortoises. As stated earlier, increases in human access can accelerate illegal collection and release of desert tortoises and deliberate maiming and killing, as well as facilitate the spread of other threats associated with human presence, such as vehicle use, garbage and dumping, and invasive weeds.

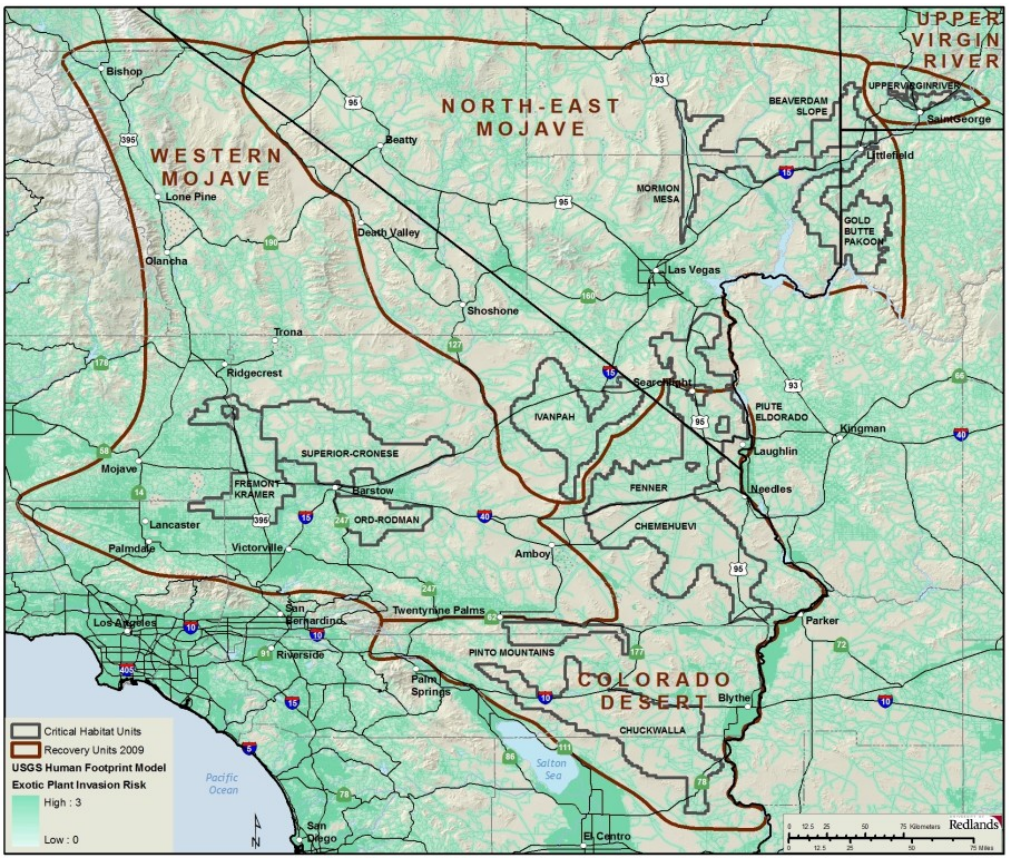
Some of the most apparent threats to the desert tortoise are those that result in mortality and permanent habitat loss across large areas, such as urbanization and large-scale renewable energy projects, and those that fragment and degrade habitats, such as proliferation of roads and highways, off-highway vehicle activity, and habitat invasion by non-native invasive plant species. However, we remain unable to quantify how threats affect desert tortoise populations.

DRAFT **DRAFT** **DRAFT**

The assessment of the original recovery plan emphasized the need for a better understanding of the implications of multiple, simultaneous threats facing desert tortoise populations and of the relative contribution of multiple threats on demographic factors (i.e., birth rate, survivorship, fecundity, and death rate; Tracy et al. 2004).

The following map depicts the 12 critical habitat units of the desert tortoise, linkages between conservation areas for the desert tortoise, and the aggregate stress that multiple, synergistic threats place on desert tortoise populations. Conservation areas include designated critical habitat, lands managed by the National Park Service, and other lands managed for the long-term conservation of the desert tortoise (e.g., the Desert Tortoise Natural Area in Kern County, California). The revised recovery plan (Service 2011e) recommended the linkages based on an analysis of least-cost pathways (i.e., areas with the highest potential to support desert tortoises) between conservation areas for the desert tortoise. This map illustrates that, across the range, desert tortoises in areas under the highest level of conservation management remain subject to numerous threats, stresses, and mortality sources.

Since the completion of the 5-year review, the Service has issued several biological opinions that affect large areas of desert tortoise habitat because of numerous proposals to develop renewable energy within its range. These biological opinions concluded that proposed solar plants were not likely to jeopardize the continued existence of the desert tortoise primarily because they were located outside of critical habitat and desert wildlife management areas that contain most of the land base required for the recovery of the species. The proposed actions also included numerous measures intended to protect desert tortoise during the construction of the projects, such as translocation of affected individuals. In aggregate, these projects would result in an overall loss of approximately 37,503 acres of habitat of the desert tortoise. We also predicted that these projects would translocate or kill up to 1,732 desert tortoises; we concluded that most of the individuals in these totals would be juveniles. To date, 372 desert tortoises have been observed during construction of projects; most of these individuals were translocated from work areas, although some desert tortoises have been killed (see Appendix 2). The mitigation required by the Bureau of Land Management and California Energy Commission, the agencies permitting these facilities, will result in the acquisition of private land within critical habitat and desert wildlife management areas and funding for the implementation of various actions that are intended to promote the recovery of the desert tortoise. Although most of these mitigation measures are consistent with recommendations in the recovery plans for the desert tortoise and the Service continues to support their implementation, we cannot assess how desert tortoise populations will respond because of the long generation time of the species.



In addition to the biological opinions issued for solar development within the range of the desert tortoise, the Service (2012e) also issued a biological opinion to the Department of the Army for the use of additional training lands at Fort Irwin. As part of this proposed action, the Department of the Army removed approximately 650 desert tortoises from 18,197 acres of the southern area of Fort Irwin, which had been off-limits to training. The Department of the Army would also use an additional 48,629 acres that lie east of the former boundaries of Fort Irwin; much of this parcel is either too mountainous or too rocky and low in elevation to support numerous desert tortoises. We provide results of the translocation later in this section.

The Service also issued a biological opinion to the Marine Corps that considered the effects of the expansion of the Marine Corps Air Ground Combat Center at Twentynine Palms (Service 2012f). We concluded that the Marine Corps' proposed action, the use of approximately 167,971 acres for training, was not likely to jeopardize the continued existence of the desert tortoise. Most of the expansion area lies within the Johnson Valley Off-high Vehicle Management Area.

The incremental effect of the larger actions (i.e., solar development, the expansions of Fort Irwin, and the Marine Corps Air Ground Combat Center) on the desert tortoise is unlikely to be positive, despite the numerous conservation measures that have been (or will be) implemented as part of the actions. The acquisition of private lands as mitigation for most of these actions increases the level of protection afforded these lands; however, these acquisitions do not create new habitat and Federal, State, and privately managed lands remain subject to most of the threats and stresses we discussed previously in this section. Although land managers have been implementing measures to manage these threats, we have been unable, to date, to determine whether the measures have been successful, at least in part because of the low reproductive

capacity of the desert tortoise. Therefore, the conversion of habitat into areas that are unsuitable for this species continues the trend of constricting the desert tortoise into a smaller portion of its range.

As the Service notes in the 5-year review (Service 2010e), "(t)he threats identified in the original listing rule continue to affect the (desert tortoise) today, with invasive species, wildfire, and renewable energy development coming to the forefront as important factors in habitat loss and conversion. The vast majority of threats to the desert tortoise or its habitat are associated with human land uses." Oftedal's work (2002 in Service 2010e) suggests that invasive weeds may adversely affect the physiological health of desert tortoises. Current information indicates that invasive species likely affect a large portion of the desert tortoise's range (see following map). Furthermore, high densities of weedy species increase the likelihood of wildfires; wildfires, in turn, destroy native species and further the spread of invasive weeds.

Global climate change is likely to affect the prospects for the long-term conservation of the desert tortoise. For example, predictions for climate change within the range of the desert tortoise suggest more frequent and/or prolonged droughts with an increase of the annual mean

temperature by 3.5 to 4.0 degrees Celsius. The greatest increases will likely occur in summer (June-July-August mean increase of as much as 5 degrees Celsius [Christensen et al. 2007 in Service 2010e]). Precipitation will likely decrease by 5 to 15 percent annually in the region with winter precipitation decreasing by up to 20 percent and summer precipitation increasing by up to 5 percent. Because germination of the desert tortoise's food plants is highly dependent on cool-season rains, the forage base could be reduced due to increasing temperatures and decreasing precipitation in winter. Although drought occurs routinely in the Mojave Desert, extended periods of drought have the potential to affect desert tortoises and their habitats through physiological effects to individuals (i.e., stress) and limited forage availability. To place the consequences of long-term drought in perspective, Longshore et al. (2003) demonstrated that even short-term drought could result in elevated levels of mortality of desert tortoises. Therefore, long-term drought is likely to have even greater effects, particularly given that the current fragmented nature of desert tortoise habitat (e.g., urban and agricultural development, highways, freeways, military training areas, etc.) will make recolonization of extirpated areas difficult, if not impossible.

The Service notes in the 5-year review that the combination of the desert tortoise's late breeding age and a low reproductive rate challenges our ability to achieve recovery. When determining whether a proposed action is likely to jeopardize the continued existence of a species, we are required to consider whether the action would "reasonably be expected, directly or indirectly, to reduce appreciably the likelihood of both the survival and recovery of a listed species in the wild by reducing the reproduction, numbers, or distribution of that species" (50 Code of Federal Regulations 402.02). Although the Service does not explicitly address these metrics in the 5-year review, we have used the information in that document to summarize the status of the desert tortoise with respect to its reproduction, numbers, and distribution.

In the 5-year review, the Service notes that desert tortoises increase their reproduction in high rainfall years; more rain provides desert tortoises with more high quality food (i.e., plants that are higher in water and protein), which, in turn, allows them to lay more eggs. Conversely, the physiological stress associated with foraging on food plants with insufficient water and nitrogen may leave desert tortoises vulnerable to disease (Oftedal 2002 in Service 2010e), and the reproductive rate of diseased desert tortoises is likely lower than that of healthy animals. Young desert tortoises also rely upon high-quality, low-fiber plants (e.g., native forbs) with nutrient levels not found in the invasive weeds that have increased in abundance across its range (Oftedal et al. 2002; Tracy et al. 2004). Compromised nutrition of young desert tortoises likely represents an effective reduction in reproduction by reducing the number that reaches adulthood. Consequently, although we do not have quantitative data that show a direct relationship, the abundance of weedy species within the range of the desert tortoise has the potential to negatively affect the reproduction of desert tortoises and recruitment into the adult population.

Data from long-term study plots, which were first established in 1976, cannot be extrapolated to provide an estimate of the number of desert tortoises on a range-wide basis; historical densities in some parts of the desert exceeded 100 adults in a square mile (Desert Tortoise Recovery Office 2014). Using data from the long-term study plots, the Service (2010) concluded that "appreciable declines at the local level in many areas, which coupled with other survey results, suggest that declines may have occurred more broadly." Other sources indicate that local

declines are continuing to occur. For example, surveyors found "lots of dead [desert tortoises]" in the western expansion area of Fort Irwin (Western Mojave Recovery Unit) in 2008 (Fort Irwin Research Coordination Meeting 2008). After the onset of translocation, coyotes killed 105 desert tortoises in Fort Irwin's southern translocation area (Western Mojave Recovery Unit); other canids may have been responsible for some of these deaths. Other incidences of predation were recorded throughout the range of the desert tortoise during this time (Esque et al. 2010). Esque et al. (2010) hypothesized that this high rate of predation on desert tortoises was influenced by low population levels of typical prey for coyotes due to drought conditions in previous years. Recent surveys in the Ivanpah Valley (Eastern Mojave Recovery Unit) for a proposed solar facility detected 31 live desert tortoises and the carcasses of 25 individuals that had been dead less than 4 years (Ironwood 2011); this ratio of carcasses to live individuals over such a short period of time may indicate an abnormally high rate of mortality for a long-lived animal. In summary, the number of desert tortoises range-wide likely decreased substantially from 1976 through 1990 (i.e., when long-term study plots were initiated through the time the desert tortoise was listed as threatened), although we cannot quantify the amount of this decrease. Additionally, more recent data collected from various sources throughout the range of the desert tortoise suggest that local declines continue to occur (e.g., Bureau of Land Management et al. 2005, Esque et al. 2010).

The distribution of the desert tortoise has not changed substantially since the publication of the original recovery plan in 1994 (Service 2010e) in terms of the overall extent of its range. Prior to 1994, desert tortoises were extirpated from large areas within their distributional limits by urban and agricultural development (e.g., the cities of Barstow and Lancaster, California; Las Vegas, Nevada; and St. George, Utah; etc.; agricultural areas south of Edwards Air Force Base and east of Barstow), military training (e.g., Fort Irwin, Leach Lake Gunnery Range), and off-road vehicle use (e.g., portions of off-road management areas managed by the Bureau of Land Management and unauthorized use in areas such as east of California City, California). Since 1994, urban development around Las Vegas has likely been the largest contributor to habitat loss throughout the range. Desert tortoises have been essentially removed from the 18,197-acre southern expansion area at Fort Irwin (Service 2012e).

The following table depicts acreages of habitat (as modeled by Nussear et al. 2009, using only areas with a probability of occupancy by desert tortoises greater than 0.5 as potential habitat) within various regions of the desert tortoise's range and of impervious surfaces as of 2006 (Fry et al. 2011). Impervious surfaces include paved and developed areas and other disturbed areas that have zero probability of supporting desert tortoises.

Recovery Units	Modeled Habitat (acres)	Impervious Surfaces within Modeled Habitat	Percent of Modeled Habitat that is now Impervious
Western Mojave	7,582,092	1,864,214	25
Colorado Desert	4,948,900	494,981	10
Northeastern Mojave	3,013,677	378,497	13

Eastern Mojave	4,763,257	794,546	17
Upper Virgin River	232,320	80,853	35
Total	20,540,246	3,613,0~~52~~91	18

Using the acreages of remaining habitat and the densities of the recovery units, the Desert Tortoise Recovery Office (2014) then estimated the number of desert tortoises greater than 180 millimeters in length in each recovery unit. The following table contains these numbers. We acknowledge that these numbers are not precise but consider it a reasonable way to describe overall changes in the population. For example, we base the density estimate of each recovery unit on surveys conducted within desert tortoise conservation areas and then extend this density to the entire recovery unit although we presume densities are highest within the conservation areas.

Recovery Units	2004	2012	Change
Western Mojave	152,967	76,644	-76,323
Colorado Desert	111,749	85,306	-26,443
Northeastern Mojave	13,709	40,838	+27,129
Eastern Mojave	68,138	42,055	-26,083
Upper Virgin River	12,678	8,399	-4,280
Total	359,242	253,242	-106,000

In conclusion, we have used the 5-year review (Service 2010e), revised recovery plan (Service 2011), and additional information that has become available since these publications to review the reproduction, numbers, and distribution of the desert tortoise. The reproductive capacity of the desert tortoise may be compromised to some degree by the abundance and distribution of invasive weeds across its range; the continued increase in human access across the desert likely continues to facilitate the spread of weeds and further affect the reproductive capacity of the species. Prior to its listing, the number of desert tortoises likely declined range-wide, although we cannot quantify the extent of the decline; since the time of listing, data suggest that declines continue to occur throughout most of the range, although recent information suggests that densities may have increased in the Northeastern Mojave Recovery Unit. The continued increase in human access across the desert continues to expose more desert tortoises to the potential of being killed by human activities. The distributional limits of the desert tortoise's range have not changed substantially since the issuance of the original recovery plan in 1994; however, desert tortoises have been extirpated from large areas within their range (e.g., Las Vegas, other desert cities). The species' low reproductive rate, the extended time required for young animals to reach breeding age, and the multitude of threats that continue to confront desert tortoises combine to render its recovery a substantial challenge.

Status of Critical Habitat of the Desert Tortoise

The Service designated critical habitat for the desert tortoise in portions of California, Nevada, Arizona, and Utah in a final rule published February 8, 1994 (59 Federal Register 5820). The Service designates critical habitat to identify the key biological and physical needs of the species

and key areas for recovery and to focus conservation actions on those areas. Critical habitat is composed of specific geographic areas that contain the biological and physical features essential to the species' conservation and that may require special management considerations or protection. These features, which include space, food, water, nutrition, cover, shelter, reproductive sites, and special habitats, are called the primary constituent elements of critical habitat. The specific primary constituent elements of desert tortoise critical habitat are: sufficient space to support viable populations within each of the six recovery units and to provide for movement, dispersal, and gene flow; sufficient quality and quantity of forage species and the proper soil conditions to provide for the growth of these species; suitable substrates for burrowing, nesting, and overwintering; burrows, caliche caves, and other shelter sites; sufficient vegetation for shelter from temperature extremes and predators; and habitat protected from disturbance and human-caused mortality.

Critical habitat of the desert tortoise would not be able to fulfill its conservation role without each of the primary constituent elements being functional. As examples, an area with a sufficient amount of forage species cannot fulfill its conservation role if human-caused mortality is excessive; an area with sufficient space to support viable populations within each of the six recovery units and to provide for movement, dispersal, and gene flow would not support desert tortoises without adequate forage species.

The final rule for designation of critical habitat did not explicitly ascribe specific conservation roles or functions to the various critical habitat units. Rather, it refers to the strategy of establishing recovery units and desert wildlife management areas recommended by the recovery plan for the desert tortoise, which had been published as a draft at the time of the designation of critical habitat, to capture the "biotic and abiotic variability found in desert tortoise habitat" (59 Federal Register 5820, see page 5823). Specifically, we designated the critical habitat units to follow the direction provided by the draft recovery plan (Service 1993) for the establishment of desert wildlife management areas. The critical habitat units in aggregate are intended to protect the variability that occurs across the large range of the desert tortoise; the loss of any specific unit would compromise the ability of critical habitat as a whole to serve its intended function and conservation role.

Despite the fact that desert tortoises do not necessarily need to move between critical habitat units to complete their life histories, both the original and revised recovery plans highlight the importance of these critical habitat units and connectivity between them for the recovery of the species. Specifically, the revised recovery plan (Service 2011a, pages 34 and 35) states that:

> (A)ggressive management as generally recommended in the 1994 Recovery Plan needs to be applied within existing (desert) tortoise conservation areas (defined as critical habitat, among other areas being managed for the conservation of desert tortoises) or other important areas … to ensure that populations remain distributed throughout the species' range …. (Desert tortoise) conservation areas capture the diversity of the Mojave population of the desert tortoise within each recovery unit, conserving the genetic breadth of the species, providing a margin of safety for the species to withstand catastrophic events, and providing potential opportunities for continued evolution and adaptive change …. Especially given uncertainties related to the effects of climate change on desert

tortoise populations and distribution, we consider (desert) tortoise conservation areas to be the minimum baseline within which to focus our recovery.

The 12 critical habitat units range in area from 85 to 1,595 square miles. However, the optimal reserve size recommended to preserve viable desert tortoise populations was 1,000 square miles (Service 1994); only 4 critical habitat units meet this threshold. Consequently, for some smaller critical habitat units, their future effectiveness in conserving the desert tortoise is largely dependent on the status of populations immediately adjacent to their boundaries or within intervening linkages that connect these smaller critical habitat units to other protected areas. Although the Service (1994) recommended the identification of buffer zones and linkages for smaller desert tortoise conservation areas, land management agencies have generally not established such areas.

Population viability analyses indicate that reserves should contain from 10,000 to 20,000 adult desert tortoises to maximize estimated time to extinction (i.e., approximately 390 years, depending on rates of population change; Service 1994). However, during the three most recent years of monitoring within the critical habitat units, only three (in 2009 and 2010) to five (in 2008) of the critical habitat units met this target (McLuckie et al. 2010; Service 2009, 2012a, 2012b). Some critical habitat units share boundaries and form contiguous blocks (e.g. Superior-Cronese and Fremont-Kramer Critical Habitat Units), and those blocks in California include combined estimated abundances of over 10,000 adult desert tortoises. Conversely, the Ord-Rodman Critical Habitat Unit is much smaller and not currently connected to other protected habitat by preserved habitat linkages.

We did not designate the Desert Tortoise Natural Area and Joshua Tree National Park in California and the Desert National Wildlife Refuge in Nevada as critical habitat because they are "primarily managed as natural ecosystems" (59 Federal Register 5820, see page 5825) and provide adequate protection to desert tortoises. Since the designation of critical habitat, Congress increased the size of Joshua Tree National Park and created the Mojave National Preserve. A portion of the expanded boundary of Joshua Tree National Park lies within critical habitat of the desert tortoise; portions of other critical habitat units lie within the boundaries of the Mojave National Preserve.

Within each critical habitat unit, both natural and anthropogenic factors affect the function of the primary constituent elements of critical habitat. As an example of a natural factor, in some specific areas within the boundaries of critical habitat, such as within and adjacent to dry lakes, some of the primary constituent elements are naturally absent because the substrate is extremely silty; desert tortoises do not normally reside in such areas. Comparing the acreage of desert tortoise habitat as depicted by Nussear et al.'s (2009) model to the gross acreage of the critical habitat units demonstrates quantitatively that the entire area within the boundaries of critical habitat likely does not support the primary constituent elements; see the following table. The acreage for modeled habitat is for the area in which the probability that desert tortoises are present is greater than 0.5. The acreages of modeled habitat are from Service (2012b); they do not include loss of habitat due to human-caused impacts. The difference between gross acreage and modeled habitat is 653,214 acres; that is, approximately 10 percent of the gross acreage of the designated critical habitat is not considered modeled habitat.

Critical Habitat Unit	Gross Acreage	Modeled Habitat
Superior-Cronese	766,900	724,967
Fremont-Kramer	518,000	501,095
Ord-Rodman	253,200	184,155
Pinto Mountain	171,700	144,056
Piute-Eldorado	970,600	930,008
Ivanpah Valley	632,400	510,711
Chuckwalla	1,020,600	809,319
Chemehuevi	937,400	914,505
Gold Butte-Pakoon	488,300	418,189
Mormon Mesa	427,900	407,041
Beaver Dam Slope	204,600	202,499
Upper Virgin River	54,600	46,441
Totals	6,446,200	5,792,986

Condition of the Primary Constituent Elements of Critical Habitat

Human activities can have obvious or more subtle effects on the primary constituent elements. The grading of an area and subsequent construction of a building removes the primary constituent elements of critical habitat; this action has an obvious effect on the primary constituent elements of critical habitat. The revised recovery plan identifies human activities such as urbanization and the proliferation of roads and highways as threats to the desert tortoise and its habitat; these threats are examples of activities that have a clear effect on the primary constituent elements of critical habitat.

We have included the following paragraphs from the revised recovery plan for the desert tortoise (Service 2011a) to demonstrate that other anthropogenic factors affect the primary constituent elements of critical habitat in more subtle ways. All references are in the revised recovery plan (i.e., in Service 2011a); we have omitted some information from the revised recovery plan where the level of detail was unnecessary for the current discussion.

> Surface disturbance from [off-highway vehicle] activity can cause erosion and large amounts of dust to be discharged into the air. Recent studies on surface dust impacts on gas exchanges in Mojave Desert shrubs showed that plants encrusted by dust have reduced photosynthesis and decreased water-use efficiency, which may decrease primary production during seasons when photosynthesis occurs (Sharifi et al. 1997). Sharifi et al. (1997) also showed reduction in maximum leaf conductance, transpiration, and water-use efficiency due to dust. Leaf and stem temperatures were also shown to be higher in plants with leaf-surface dust. These effects may also impact desert annuals, an important food source for [desert] tortoises.
>
> [Off-highway vehicle] activity can also disturb fragile cyanobacterial-lichen soil crusts, a dominant source of nitrogen in desert ecosystems (Belnap 1996). Belnap (1996) showed that anthropogenic surface disturbances may have serious implications for nitrogen budgets in cold desert ecosystems, and this may also hold true for the hot deserts that

> [desert] tortoises occupy. Soil crusts also appear to be an important source of water for plants, as crusts were shown to have 53 percent greater volumetric water content than bare soils during the late fall when winter annuals are becoming established (DeFalco et al. 2001). DeFalco et al. (2001) found that non-native plant species comprised greater shoot biomass on crusted soils than native species, which demonstrates their ability to exploit available nutrient and water resources. Once the soil crusts are disturbed, non-native plants may colonize, become established, and out-compete native perennial and annual plant species (DeFalco et al. 2001, D'Antonio and Vitousek 1992). Invasion of non-native plants can affect the quality and quantity of plant foods available to desert tortoises. Increased presence of invasive plants can also contribute to increased fire frequency.
>
> Proliferation of invasive plants is increasing in the Mojave and Sonoran deserts and is recognized as a substantial threat to desert tortoise habitat. Many species of non-native plants from Europe and Asia have become common to abundant in some areas, particularly where disturbance has occurred and is ongoing. As non-native plant species become established, native perennial and annual plant species may decrease, diminish, or die out (D'Antonio and Vitousek 1992). Land managers and field scientists identified 116 species of non-native plants in the Mojave and Colorado deserts (Brooks and Esque 2002).
>
> Increased levels of atmospheric pollution and nitrogen deposition related to increased human presence and combustion of fossil fuels can cause increased levels of soil nitrogen, which in turn may result in significant changes in plant communities (Aber et al. 1989). Many of the non-native annual plant taxa in the Mojave region evolved in more fertile Mediterranean regions and benefit from increased levels of soil nitrogen, which gives them a competitive edge over native annuals. Studies at three sites within the central, southern, and western Mojave Desert indicated that increased levels of soil nitrogen can increase the dominance of non-native annual plants and promote the invasion of new species in desert regions. Furthermore, increased dominance by non-native annuals may decrease the diversity of native annual plants, and increased biomass of non-native annual grasses may increase fire frequency (Brooks 2003).

This summary from the revised recovery plan (Service 2011a) demonstrates how the effects of human activities on habitat of the desert tortoise are interconnected. In general, surface disturbance causes increased rates of erosion and generation of dust. Increased erosion alters additional habitat outside of the area directly affected by altering the nature of the substrate, removing shrubs, and possibly destroying burrows and other shelter sites. Increased dust affects photosynthesis in the plants that provide cover and forage to desert tortoises. Disturbed substrates and increased atmospheric nitrogen enhance the likelihood that invasive species will become established and outcompete native species; the proliferation of weedy species increases the risk of large-scale fires, which further move habitat conditions away from those that are favorable to desert tortoises.

The following paragraphs generally describe how the threats described in the revised recovery plan affect the primary constituent elements of critical habitat of the desert tortoise.

Sufficient space to support viable populations within each of the six recovery units and to provide for movement, dispersal, and gene flow.

In considering the following discussion, bear in mind the information provided previously in this biological opinion regarding the recommended and actual sizes of critical habitat units for the desert tortoise. The original recovery team based the recommended size of desert wildlife management areas on the amount of space required to maintain viable populations. (The recovery plan [Service 1994] defined conservation areas for the desert tortoise as 'desert wildlife management areas;' we based the boundaries of critical habitat on the recovery team's general recommendation for the desert wildlife management areas.) The current low densities of desert tortoises within critical habitat units exacerbate the difficulties of effecting recovery within these areas.

Urban, industrial, and agricultural development, concentrated use by off-road vehicles, and other activities of this nature completely remove habitat. Although we are aware of local areas within the boundaries of critical habitat that have been heavily disturbed, we do not know of any areas that have been disturbed to the intensity and extent that this primary constituent element has been compromised. To date, the largest single loss of critical habitat is the use of 18,197 acres of additional training land in the southern portion of Fort Irwin. In our biological opinion for that proposed action (Service 2012e), we stated:

> The proposed action would essentially eliminate the primary constituent elements from approximately 2.40 percent of the Superior-Cronese Critical Habitat Unit; additionally, the conservation role of the remainder of this critical habitat unit and the other critical habitat units has been compromised by substantial human impact on the second and sixth primary constituent elements. However, the protective measures that the Army implemented as part of the proposed action offset, at least to some extent, the adverse effects of the use of the additional training lands in the southern expansion area. Consequently, we have concluded that, although the second and sixth primary constituent elements are not functioning appropriately throughout most of designated critical habitat of the desert tortoise and the proposed action would result in substantial disturbance to 18,197 acres of the Superior-Cronese Critical Habitat Unit, the change in the condition of critical habitat brought about by the Army's proposed action (i.e., use of the southern expansion area for training and implementation of the conservation actions) is not likely to cause an overall decrease in the conservation value and function of the Superior-Cronese Critical Habitat Unit.

The widening of existing freeways likely caused the second largest loss of critical habitat. Despite these losses of critical habitat, which occur in a linear manner, the critical habitat units continue to support sufficient space to support viable populations within each of the six recovery units.

In some cases, major roads likely disrupt the movement, dispersal, and gene flow of desert tortoises. Highways 58 and 395 in the Fremont-Kramer Critical Habitat Unit and Fort Irwin Road in the Superior-Cronese Critical Habitat Unit are examples of large and heavily travelled

roads that likely disrupt movement, dispersal, and gene flow. Roads that have been fenced and provided with underpasses may alleviate this fragmentation to some degree; however, such facilities have not been in place for sufficient time to determine whether they will eliminate fragmentation.

The threats of invasive plant species described in the revised recovery plan generally do not result in the removal of this primary constituent element because they do not convert habitat into impervious surfaces, as would urban development.

Sufficient quality and quantity of forage species and the proper soil conditions to provide for the growth of these species.

This primary constituent element addresses the ability of critical habitat to provide adequate nutrition to desert tortoises. As described in the revised recovery plan and 5-year review, grazing, historical fire, invasive plants, altered hydrology, drought, wildfire potential, fugitive dust, and climate change/temperature extremes contribute to the stress of "nutritional compromise." Paved and unpaved roads through critical habitat of the desert tortoise provide avenues by which invasive native species disperse; these legal routes also provide the means by which unauthorized use occurs over large areas of critical habitat. Nitrogen deposition from atmospheric pollution likely occurs throughout all the critical habitat units and exacerbates the effects of the disturbance of substrates. Because paved and unpaved roads are so widespread through critical habitat, this threat has compromised the conservation value and function of critical habitat throughout the range of the desert tortoise, to some degree. See the Status of the Desert Tortoise section of this biological opinion for a map that depicts the routes by which invasive weeds have access to critical habitat; the routes shown on the map are a subset of the actual number of routes that actually cross critical habitat of the desert tortoise.

Suitable substrates for burrowing, nesting, and overwintering.

Surface disturbance, motor vehicles traveling off route, use of off-highway vehicle management areas, off-highway vehicle- events, unpaved roads, grazing, historical fire, wildfire potential, altered hydrology, and climate change leading to shifts in habitat composition and location, storms, and flooding can alter substrates to the extent that they are no longer suitable for burrowing, nesting, and overwintering. Erosion caused by these activities can alter washes to the extent that desert tortoise burrows placed along the edge of a wash, which is a preferred location for burrows, could be destroyed. We expect that the area within critical habitat that is affected by off-road vehicle use to the extent that substrates are no longer suitable is relatively small in relation to the area that desert tortoises have available for burrowing, nesting, and overwintering; consequently, off-road vehicle use has not had a substantial effect on this primary constituent element.

Most livestock allotments have been eliminated from within the boundaries of critical habitat. Of those that remain, livestock would compact substrates to the extent that they would become unsuitable for burrowing, nesting, and overwintering only in areas of concentrated use, such as around watering areas and corrals. Because livestock grazing occurs over a relatively small portion of critical habitat and the substrates in most areas within livestock allotments would not

be substantially affected, suitable substrates for burrowing, nesting, and overwintering remain throughout most of the critical habitat units.

Burrows, caliche caves, and other shelter sites.

Human-caused effects to burrows, caliche caves, and other shelter sites likely occur at a similar rate as effects to substrates for burrowing, nesting, and overwintering for the same general reasons. Consequently, sufficient burrows, caliche caves, and other shelter sites remain throughout most of the critical habitat units.

Sufficient vegetation for shelter from temperature extremes and predators.

In general, sufficient vegetation for shelter from temperature extremes and predators remains throughout critical habitat. In areas where large fires have occurred in critical habitat, many of the shrubs that provide shelter from temperature extremes and predators have been destroyed; in such areas, cover sites may be a limiting factor. The proliferation of invasive plants poses a threat to shrub cover throughout critical habitat as the potential for larger and more frequent wildfires increases.

In 2005, wildfires in Nevada, Utah, and Arizona burned extensive areas of critical habitat (Service 2010a). Although different agencies report slightly different acreages, the following table provides an indication of the scale of the fires.

Critical Habitat Unit	Total Area Burned (acres)	Percent of the Critical Habitat Unit Burned
Beaver Dam Slope	53,528	26
Gold-Butte Pakoon	65,339	13
Mormon Mesa	12,952	3
Upper Virgin River	10,557	19

The revised recovery plan notes that the fires caused statistically significant losses of perennial plant cover, although patches of unburned shrubs remained. Given the patchiness with which the primary constituent elements of critical habitat are distributed across the critical habitat units and the varying intensity of the wildfires, we cannot quantify precisely the extent to which these fires disrupted the function and value of the critical habitat.

Habitat protected from disturbance and human-caused mortality.

In general, the Federal agencies that manage lands within the boundaries of critical habitat have adopted land management plans that include implementation of some or all of the recommendations contained in the original recovery plan for the desert tortoise. (See pages 70 to 72 of Service 2010b.) To at least some degree, the adoption of these plans has resulted in the implementation of management actions that are likely to reduce the disturbance and human-caused mortality of desert tortoises. For example, these plans resulted in the designation of open routes of travel and the closure (and, in some cases, physical closure) of unauthorized routes. Permittees have relinquished numerous livestock allotments and cattle no longer graze

these allotments. Because of these planning efforts, some of the Bureau's records of decision included direction to withdraw some areas of critical habitat from mineral entry. Because of actions on the part of various agencies, many miles of highways and other paved roads have been fenced to prevent desert tortoises from wandering into traffic and being killed. The Service and other agencies of the Desert Managers Group in California are implementing a plan to remove common ravens that prey on desert tortoises and to undertake other actions that would reduce subsidies (i.e., food, water, sites for nesting, roosting, and perching, etc.) that facilitate their abundance in the California desert (Service 2008).

Despite the implementation of these actions, disturbance and human-caused mortality continue to occur in many areas of critical habitat (which overlap the desert wildlife management areas for the most part and are the management units for which most data are collected) to the extent that the conservation value and function of critical habitat is, to some degree, compromised. For example, many highways and other paved roads in California remain unfenced. Twelve desert tortoises were reported to be killed on paved roads from within Mojave National Preserve in 2011, and we fully expect that desert tortoises are being killed at similar rates on many other roads, although these occurrences are not discovered and reported as diligently as by the National Park Service. Employees of the Southern California Gas Company reported two desert tortoises in 2011 that were crushed by vehicles on unpaved roads.

Unauthorized off-road vehicle use continues to disturb habitat and result in loss of vegetation within the boundaries of critical habitat (e.g., Coolgardie Mesa in the Western Mojave Recovery Unit); although we have not documented the death of desert tortoises as a direct result of this activity, it likely occurs. Additionally, the habitat disturbance caused by this unauthorized activity exacerbates the spread of invasive plants, which displace native plants that are important forage for the desert tortoise, thereby increasing the physiological stress faced by desert tortoises.

Although the Bureau has approved, through its land use planning processes, the withdrawal of areas of critical habitat from mineral entry, it has not undertaken the administrative procedures to complete withdrawals in all areas. Absent this withdrawal, new mining claims can be filed and further disturbance of critical habitat could occur.

Finally, the Bureau has not allowed the development of solar power plants on public lands within the boundaries of its desert wildlife management areas (which largely correspond to the boundaries of critical habitat). Conversely, the County of San Bernardino is considering the approval of the construction and operation of at least two such facilities within the boundaries of the Superior-Cronese Critical Habitat Unit north of Interstate 15 near the Minneola Road exit.

Summary of the Status of Critical Habitat of the Desert Tortoise

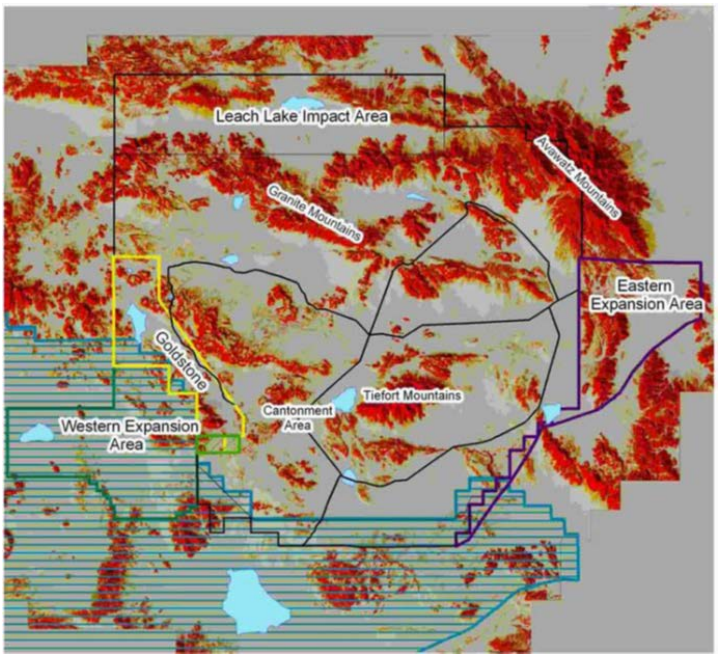
As noted in the revised recovery plan for the desert tortoise and 5-year review (Service 2011a, 2010a), critical habitat of the desert tortoise is subject to landscape level impacts in addition to the site-specific effects of individual human activities. On the landscape level, atmospheric pollution is increasing the level of nitrogen in desert substrates; the increased nitrogen exacerbates the spread of invasive plants, which out compete the native plants necessary for desert tortoises to survive. As invasive plants increase in abundance, the threat of large wildfires

increases; wildfires have the potential to convert the shrubland-native annual plant communities upon which desert tortoises depend to a community with fewer shrubs and more invasive plants. In such a community, shelter and forage would be more difficult for desert tortoises to find. Invasive plants have already compromised the conservation value and function of critical habitat to some degree with regard to the second primary constituent element (i.e., sufficient quality and quantity of forage species and the proper soil conditions to provide for the growth of these species). These effects likely extend to the entirety of critical habitat, given the numerous routes by which invasive plants can access critical habitat and the large spatial extent that is subject to nitrogen from atmospheric pollution. (See maps from previous sections of this biological opinion regarding the extent of the threat of invasive plants and the aggregate stress that multiple threats, including invasive plants, place on critical habitat.)

Critical habitat has been compromised to some degree with regard to the last primary constituent element (i.e., habitat protected from disturbance and human-caused mortality) as a result of the wide variety of human activities that continues to occur within its boundaries. These effects result from the implementation of discrete human activities and are thus more site-specific in nature.

Although the remaining primary constituent elements have been affected to some degree by human activities, these impacts have not, to date, substantially compromised the conservation value and function of the critical habitat units. We have reached this conclusion primarily because the effects are localized and thus do not affect the conservation value and function of large areas of critical habitat.

Land managers have undertaken actions to improve the status of critical habitat. For example, as part of its efforts to offset the effects of the use of additional training maneuver lands at Fort Irwin (Service 2004), the Army acquired the private interests in the Harper Lake and Cronese Lakes allotments, which are located within critical habitat in the Western Mojave Recovery Unit; as a result, cattle have been removed from these allotments. Livestock have been removed from numerous other allotments through various means throughout the range of the desert tortoise. The retirement of allotments assists in the recovery of the species by eliminating disturbance to the primary constituent elements of critical habitat by cattle and range improvements.



ENVIRONMENTAL BASELINE

Action Area

The implementing regulations for section 7(a)(2) of the Act define the “action area” as all areas to be affected directly or indirectly by the Federal action and not merely the immediate area involved in the action (50 Code of Federal Regulations 402.02). The action area for this biological opinion is the footprint of Fort Irwin, which consists of approximately 755,606 acres and the route of the Manix Trail, which extends from Interstate 15 south of Fort Irwin to the southern area of the installation east of Fort Irwin Road, as depicted on the following map. The Army uses the Manix Trail to bring equipment to Fort Irwin; the portion outside of Fort Irwin is approximately 14 miles long.

General Description of Fort Irwin

To accommodate these activities, the Army has divided Fort Irwin into several major areas. The following map and discussion provide information on the location and activities in these areas.

The blue crosshatched area depicts critical habitat of the desert tortoise (i.e., a portion of the Superior-Cronese Critical Habitat Unit). Blue areas are dry lakes. The southern expansion area is the area where critical habitat overlaps the southern portion of Fort Irwin. The Manix Trail lies to the east of the southernmost dry lake.

Leach Lake Gunnery Range

The Leach Lake Gunnery Range is located within the Leach Lake Impact Area and covers 92,625 acres in the northern portion of Fort Irwin. Since 1967, the Air Force, Navy, and Marine Corps have used this range year-round for air-to-air and air-to-ground gunnery and as an east-west, low-level flight corridor. Numerous types of military aircraft (fighters and bombers) use Leach Lake. The Leach Lake Gunnery Range is extensively contaminated with unexploded ordnance, which has been deposited since World War II. Unexploded ordnance ranges from 2,000-pound bombs to highly sensitive cluster bombs. The Air Force periodically removes unexploded ordnance from this area; the Air Force personnel follow the same procedures used to protect desert tortoises that the Army uses throughout Fort Irwin when conducting these activities (Everly 2014).

Goldstone Deep Space Communications Complex

The Army leases 33,241 acres, generally on the western boundary of Fort Irwin, to the National Aeronautics and Space Administration to operate the Goldstone Deep Space Communications Complex. The National Aeronautics and Space Administration tracks satellites and conducts other deep-space work at this facility. Little military training occurs within this area. The Army has ultimate responsibility for the management of natural resources on Goldstone, although the National Aeronautics and Space Administration has its own environmental program for the area. This biological opinion addresses any actions that the Army may undertake in this area, including future activities on approximately 1,000 acres of the leased area for which the Army will soon resume management.

Cantonment Area

The cantonment area is located in the southwestern portion of Fort Irwin. The cantonment area is nearly completely developed and supports the installation's day-to-day operations, administrative activities, family housing and neighborhood parks, barracks, maintenance yards, indoor recreation, restaurant facilities, and equipment ~~posts~~yards. This area occupies 15,314 acres.

Downrange Operations Area

Task force live-fire exercises are conducted primarily north of the Granite Mountains (the northern corridor). The majority of force-on-force maneuvers take place in the central corridor, which lies south of the Granite Mountains and north of Tiefort Mountain. The southern corridor lies south of Tiefort Mountain and is used primarily for staging and also for maneuver training.

The Downrange Operations Area includes the western expansion area, the southern expansion area, and the Eastgate parcel. The entire area covers 501,551 acres. Approximately 3,250 acres of Fort Irwin are off limits to military training because of archeological resources; the Army uses an additional 7,166 acres for recreation.

Conservation Areas

As part of its proposed action for using additional maneuver training lands, the Army established four conservation areas for the desert tortoise along the boundary of the installation. The 4 conservation areas and a 500-meter-wide buffer to the north of the Boulder Utility Corridor comprise approximately 11,016 acres. All of these conservation areas have been designated by the Army as off limits to training and secured through the placement of desert tortoise fencing and signing. This fencing separates the conservation areas from the southern expansion area where training would occur.

Habitat Characteristics of the Action Area

The integrated natural resources management plan (Army 2006 - 2011) contains detailed information on the habitat characteristics of Fort Irwin. The plant communities on base that are of importance to the desert tortoise are creosote bush scrub, Mojave mixed woody scrub, saltbush scrub, Joshua tree woodland, blackbush scrub, and Mojave desert wash scrub. Some

areas of Fort Irwin show signs of intense training; these areas are generally located where vehicles, included tracked and wheeled vehicles, can traverse the terrain. Other areas that are more inaccessible to vehicles exhibit much less disturbance.

Previous Consultations in the Action Area

Prior to the withdrawal of the lands for the expansion of Fort Irwin in 2002, the Bureau and Service conducted one substantial consultation on the desert tortoise that affected management of the Superior Valley parcel. On April 11, 1991, we issued a biological opinion to the Bureau in which we concluded that the Bureau's ephemeral sheep grazing program in the western Mojave Desert was likely to jeopardize the continued existence of the desert tortoise (Service 1991b). Sheep have not grazed within the Superior Valley parcel since 1989 because of drought and, since 1991, because of the Service's biological opinion.

In 1991, the Army and Service formally consulted on the effects of the ongoing training at Fort Irwin on the desert tortoise (Service 1991a). This biological opinion addressed the Army's training activities within its boundaries prior to expansion; it did not address any other activities. The area south of the UTM 90 line (i.e., the northern limit of the southern expansion area) was established as off-limits to vehicles traveling off-road as a result of the consultation; at the time the consultation was completed, the distribution and abundance of desert tortoises had already been altered by decades of training (Service 1991a). The Service concluded that the continued training at Fort Irwin was not likely to jeopardize the continued existence of the desert tortoise because most activities occurred in areas that had been affected by training prior to the listing of the desert tortoise.

The Service (1992) issued a biological opinion to the National Aeronautics and Space Administration for the installation of a fiber optic cable within the boundaries of the Goldstone Deep Space Communications Complex. The Service concluded that the proposed action was not likely to jeopardize the continued existence of the desert tortoise; to the best of our knowledge, no desert tortoises were killed during the installation of the cable.

On February 23, 1998, the Service issued a biological opinion to the National Aeronautics and Space Administration for construction activities at the Goldstone Deep Space Communications Complex. In this biological opinion, the Service concluded that routine construction, operations, and maintenance activities at the Goldstone Deep Space Communications Complex were not likely to jeopardize the continued existence of the desert tortoise or result in destruction or adverse modification of its critical habitat because a relatively small number of desert tortoises and amount of critical habitat would be affected. We are not aware of any desert tortoises that have been injured or killed as a result of operations at the Goldstone Deep Space Communications Complex. In 2012, workers observed two desert tortoises on roads within the complex and moved these animals to safety (National Aeronautics and Space Administration 2013).

On April 19, 2002, we issued a biological opinion to the Army regarding a survey of the revised boundary of Fort Irwin (Service 2002). We found that the proposed action was not likely to jeopardize the continued existence of the desert tortoise or adversely modify its critical habitat

because the Army included measures in its project description to avoid desert tortoises, few individuals were likely to be killed or injured by the surveys, and disturbance of habitat would be temporary. The proposed action involved placement of markers along the new boundaries of the installation; access was by pick-up truck and all-terrain vehicles, and on foot. The Army committed to attempting to avoid desert tortoises when traveling through the project area. The survey was completed in 2004; no desert tortoises were encountered during the work (Army 2009b).

On May 31, 2002, the Service (2002) issued a biological opinion to the Army for the development and operation of an off-road vehicle area for use by Army personnel. The Service concluded that the development and operation of this 625-acre area was not likely to jeopardize the continued existence of the desert tortoise.

On June 9, 2003, we issued a biological opinion to the Army regarding the installation of a fiber optic cable between Fort Irwin and the Naval Air Weapons Station, China Lake (Service 2003b). We found that the proposed action was not likely to jeopardize the continued existence of the desert tortoise or adversely modify its critical habitat because the Army included measures in its project description to avoid killing or injuring animals and only a small area of habitat would be temporarily disturbed. The cable was installed in a 12-inch wide trench along a 32-mile long route; most of the installation was either within roads or their shoulders. The cable was installed in 2006. Only one desert tortoise was observed and moved from harm's way during installation; installation of the cable disturbed approximately 114 acres of critical habitat within the Superior-Cronese Critical Habitat Unit (Army 2009c).

The initial biological opinion for the current proposed use of additional training lands (Service 2004) analyzed the effects that closure of existing mines and installation of an exclusion fence on the boundary of Fort Irwin might have on the desert tortoise. The mine work has been completed; no desert tortoises were found in the mines that were closed (Everly 2009b). To the best of our knowledge, no desert tortoises were killed or injured during installation of the perimeter fence.

Additionally, as part of the 2004 consultation, the Army proposed to create an improved transit route for vehicles through the Goldstone Deep Space Communications Complex, which is managed by the National Aeronautics and Space Administration. The Army has completed the 3-mile long transit route; it did not report any issues with desert tortoises during this work, which is not unexpected, given the low numbers of desert tortoises in the area crossed by the road. The Army has not added gravel or a resin-impregnated topcoat (e.g., latex-polymer impregnated into the top few inches of surface gravels) to control dust as use of this road for training purposes is in abeyance until the Army concludes analysis on the future use of the western expansion area~~; this work is scheduled to occur in the summer of 2012~~. We do not expect that the road coating, if and when applied, would affect desert tortoises or their habitat because it would occur entirely on the existing disturbed surface. This transit route would be used to transport troops and equipment between the cantonment area and the ~~Superior Valley~~Western Expansion parcel.

We discussed the most recent biological opinion regarding the use of additional maneuver training lands in the Status of the Desert Tortoise and Critical Habitat - Status of the Desert Tortoise section of this biological opinion.

Existing Conditions in the Action Area

In this section, we discuss the anthropogenic and natural conditions in the action area as they relate to desert tortoises and their habitat. Unless we have noted otherwise by citing a biological opinion, the anthropogenic conditions present in the action area were constructed or instituted prior to the listing of the desert tortoise. We summarized the following information from the integrated natural resources management plan (Army 2006 -2011) and communications with personnel at Fort Irwin.

Use by Feral and Domestic Livestock

Feral burros (*Equus africanus asinus*) graze portions of Fort Irwin. Burros likely have the same effect on desert tortoises as domestic livestock. That is, they can trample desert tortoises, particularly small individuals and degrade habitat though the trampling and grazing of the plants that desert tortoises use for food and shelter. Burros also introduce surface disturbance that can facilitate the spread of invasive plants. They also likely trample the burrows of desert tortoises, which would remove their shelters and possibly trap them inside. As of 2006, the Army noted that approximately 70 burros resided in the Leach Lake area and at Bitter Springs. Burros also reside in the western expansion area; the Army did not know the size of this herd. The grazing of domestic livestock does not occur at Fort Irwin.

Non-native Species

The processes of grazing, urbanization, agriculture, and road and utility construction have resulted in the introduction into the western Mojave Desert of invasive annuals, particularly split grass (*Schismus barbatus*), cheat grass (*Bromus tectorum*), red brome (*B. madritensis* ssp. *rubens*), filaree (*Erodium cicutarium*), and Sahara mustard (*Brassica tournefortii*). The abundance and diversity of non-native species in any area vary in relation to the seasonal weather; consequently, the composition of the non-native plant flora may be substantially different from year to year. An overabundance of weedy species likely compromises the nutritional status of desert tortoises, as we discussed in the Status of the Desert Tortoise section of this biological opinion. We do not have specific information on the distribution of non-native species nor on their specific effects on desert tortoises in the action area. The Army acknowledges the presence of invasive plant species in its integrated natural resources management plan and has mechanisms in place to manage weeds.

Formatted: Font: 12 pt

Paved and Unpaved Roads

Fort Irwin Road is the main paved road that traverses desert tortoise habitat within Fort Irwin, although desert tortoises likely attempt to cross the outermost paved roads that lie adjacent to the cantonment area. Fort Irwin Road provides access to the base by most workers and is heavily used. We expect that the density of desert tortoises adjacent to this road is depressed, as

discussed by Hoff and Marlow (2002), but we are not aware of surveys that quantify this effect within Fort Irwin.

Utilities

The most substantial ongoing effect of utility poles is their ongoing use by common ravens for perching and nesting. The presence of this additional nesting substrate, which allows common ravens to nest far above the reach of ground-dwelling predators, likely contributes substantially to the increase in the number of common ravens in the desert. As previously discussed, common ravens prey on desert tortoises and are likely detrimental to the recovery of the desert tortoise.

The need for road maintenance on the utility corridors has left permanent bare areas. Roads along and above utility corridors are occasionally used for maintenance. Most transmission lines on Fort Irwin are located within or lead to the cantonment area.

Status of the Desert Tortoise in the Action Area

The Army has not undertaken any systematic surveys of the entire area within its boundaries. With a few exceptions, however, the Army and Service have a reasonable understanding of the status of desert tortoises at Fort Irwin. In the following paragraphs, we will provide this information for each general area of the installation.

Leach Lake Gunnery Range

The Army has not conducted surveys for desert tortoises within the Leach Lake Gunnery Range because unexploded ordnance renders the area unsafe. Based on the elevation within the gunnery range and its location within the central Mojave Desert, we expect that desert tortoises occur in the area although desert tortoises are absent from or very sparsely distributed in the area immediately to the north of Leach Lake, which lies within Death Valley National Park.

Within this area, we expect that desert tortoises would occur in low densities in target areas. The potential exists for desert tortoises to occur in at least slightly higher densities on the upper slopes of alluvial fans in this area, farther away from targets.

Goldstone Deep Space Communications Complex

Information regarding the status of desert tortoises within the Goldstone Deep Space Communications Complex comes from surveys conducted in 1983 and 1989. We included the following description of the status of the desert tortoise in this area from the biological opinion for the complex's routine operation (Service 1998; all citations in the following paragraphs are from Service 1998.).

> Within suitable habitats, [desert tortoises] are probably more common in less rocky, alluvial areas and less common on rocky hillsides and mountainous areas. This statement is supported by two comprehensive surveys performed on the [Goldstone Deep Space Communications Complex] in 1983 (Woodman et al. 1984 in [Circle Mountain Biological

Consultants] 1997) and in 1989 (Woodman and Goodlett 1990 in [Circle Mountain Biological Consultants] 1997). These surveys documented limited signs in predominantly rocky areas, hard pan, or loose, sandy soils. The more favorable habitats occurred on firm sandy-loam to gravelly soils of alluvial fans or bajadas. Higher estimated tortoise densities were noted within an elevation range of 1,600 to 3,600 feet. These more preferred habitats were typically represented by the creosote scrub plant community (Munz 1974 in [Circle Mountain Biological Consultants] 1997) dominated by creosote bush, white bursage, desert senna (*Cassia armata*), goldenhead (*Acamptopappus sphaerocephalus*), and Cooper goldenbush.

Anecdotal accounts indicate that desert tortoises may be more common in areas south of Goldstone Lake and south and east of the Venus Site (LaRue, pers. obs. and maps maintained at [Goldstone Deep Space Communications Complex] in [Circle Mountain Biological Consultants] 1997). Goldstone Deep Space Communications Complex personnel regularly see desert tortoises crossing NASA Road between its junction with Goldstone Road and the southern boundary of [Goldstone Deep Space Communications Complex]. Various studies performed by [Circle Mountain Biological Consultants] and Tierra Madre Consultants, Inc. (1991, 1992, 1993a, 1993b in [Circle Mountain Biological Consultants] 1997) tend to support this generalization.

Cantonment Area

Most of the cantonment area is developed with infrastructure and is heavily used by Fort Irwin's personnel. Consequently, the remaining areas of desert tortoise habitat exist in smaller patches. Desert tortoises occasionally wander into this area but it generally does not support a viable population.

Downrange Operations Area

Within the boundary of Fort Irwin prior to its expansion, desert tortoises occur in extremely low numbers in areas that have been used for force-on-force training. More desert tortoises occur on the upper slopes of the alluvial fans that surround training areas, probably because the more rugged terrain in these areas is not conducive to the large-scale movement of military vehicles.

The southern expansion area comprises the southernmost portion of the downrange area. As a result of the consultation on the use of additional maneuver training lands, the Army translocated most of the desert tortoises in this area onto Army lands south of the training areas. We expect that the surveys to remove desert tortoises missed a few individuals and that others may have moved into this area from surrounding habitat on Fort Irwin; the Army also left desert tortoises in place that it deemed were not suitable for translocation (i.e., those that had evidence of disease but were not so debilitated that they were euthanized). At the present time, when the Army finds healthy desert tortoises in this area, it translocates them to its conservation areas on the southern edge of Fort Irwin. A mesh fence to exclude desert tortoises separates the southern expansion area from the conservation areas and other desert tortoise habitat to the south.

The western expansion area supports approximately 626 to 658 adult desert tortoises; the

approximate confidence interval for this estimate is from 516 to 1,143 adults. The 2004 biological opinion for the use of additional maneuver training lands describes how these numbers were derived (Service 2004). Desert tortoises are generally distributed patchily in this area, with the lowest densities near the Superior Dry Lakes. The Army initially separated this area from adjacent habitat with a mesh fence to prepare to translocat~~ion~~ desert tortoises; during the time that it is evaluating the future use of this area, it has installed openings in the fence to allow passage by desert tortoises.

Desert tortoises within the Eastgate parcel are generally confined to the area where the alluvial fan joins the mountainous areas to the west of the alluvial fan (Everly 2012b). The alluvial fan downslope from this area is extremely rocky. The alluvial fan is also somewhat below elevations at which desert tortoises most frequently occur and thus may be hotter and receive less rainfall than areas to the east. These factors may be responsible for desert tortoises being largely restricted to the upper alluvial fan where, presumably, temperatures are cooler and rainfall more abundant. In 2004, the Army estimated that approximately 288 desert tortoises reside in this parcel (Service 2004).

Conservation Areas

These areas to the south of the southern expansion area generally contain high quality habitat for desert tortoises; surveys completed in preparation of the translocation of desert tortoises from the southern expansion area indicated that these areas generally supported numerous desert tortoises. Since that time, the Army has translocated additional desert tortoises into these areas. During the first year after the translocation, drought conditions in the area caused coyotes to prey heavily on translocated, resident, and ~~resident~~control desert tortoises; although the predation was greatest closer to areas of human habitation, some desert tortoises also perished in the conservation areas. We do not know current densities in these areas.

Effects of Army Activities on the Desert Tortoise

The original biological assessment for use of additional training lands (Charis Professional Services Corporation 2003) notes that 36 desert tortoises were killed at Fort Irwin during military maneuvers between 1994 and 2002; an additional 85 desert tortoises were moved from harm's way during this period. By letter dated June 16, 2003, the Army (2003) notified us that four desert tortoises had been killed in fiscal year 2003 as of the date of the letter. The following table provides information on encounters with desert tortoises at Fort Irwin since that time.

Calendar Year	Encounters with Desert Tortoises	Carcasses	Relocations	Mortality Resulting from Army Activity
1994 - 2002	-	-	85	40
2003	-	-	-	4
2004	27	4	3	0
2005	20	2	2	1
2006	14	11	3	0
2007	9	14	2	0
2008	6	5	2	0

2009	30	16	14	1
2010	34	0	16	0
2011	37	2	12	1
2012	13	26	5	1
Totals	190	8~~1~~0	144	48

'Encounters with Desert Tortoises' includes observations of live animals that were not at risk and not relocated.
'Carcasses' includes observations of dead animals where the cause of death seemed to be natural or could not be determined.
'Relocations' includes desert tortoises that were moved from harm's way.
A dash indicates that data are not available.
The information contained in this table is from Charis Professional Services Corporation (2003), Army (2003), and the Army's annual reports (Army 2005, 2006, 2007, 2008, 2009a, 2010c, 2011b, 2012b, 2013).

The Army is unlikely to find every desert tortoise that dies as a result of its activities. Although we expect that the Army's activities have killed more than 4~~4~~8 desert tortoises since its listing, we also expect that the overall number of animals that have died is unlikely to be substantially more than that observed by the Army. We have reached this conclusion because the generally low density of desert tortoises on base in areas of high levels of activity likely decreases the frequency of interactions between the Army's activities and desert tortoises; additionally, the Army moved almost all of the desert tortoises within the southern expansion area either into its conservation areas or into the southern translocation area as a result of consultations on the use of additional training lands at Fort Irwin. Finally, the intensity of monitoring employed by the Army and the general high level of awareness of desert tortoises by base personnel in general likely add further protection to individuals of this species.

Status of Critical Habitat of the Desert Tortoise in the Action Area

We obtained the information in this section from the Service's (2012) biological opinion regarding the use of additional training maneuver lands at Fort Irwin. Fort Irwin overlaps the Superior-Cronese Critical Habitat Unit, extending along the southern portion of the installation from its southwestern corner in the western expansion area to as far east as the Whale. Within Fort Irwin, critical habitat can generally be thought of as occurring within three general areas: the western expansion area, the Goldstone Deep Space Communications Complex, and the southern expansion area.

Congress transferred the approximately 70,045 acres within the western expansion area from the Bureau to the Army in 2002. (The entire amount of land transferred was 118, 674 acres, of which 48,629 acres are in the Eastgate parcel.) Since that time, the Army fenced the boundary to prevent access from adjacent lands; this fence also includes mesh to preclude entry by desert tortoises. After the Army postponed use of the western expansion area for training in 2012, it opened some sections of the desert tortoise fence to allow animals to move in and out of this area. This area was previously grazed by domestic sheep prior to 1989; we do not know how habitat conditions have changed since this grazing ended. The area includes several unpaved roads that were present when the land transfer occurred.

Comment [c11]: 21 November 2011 per the G3 guys (Crosbie and Negrete).

Critical habitat overlaps approximately 4,284 acres within the Goldstone Deep Space Communications Complex (Everly 2014). The Army does not conduct maneuvers in this area but uses roads to traverse the complex. In general, habitat within this area is relatively undisturbed.

The southern expansion area covers approximately 23,214 acres. This area is within the original boundaries of Fort Irwin. At the time the desert tortoise was listed in 1989, the nature of training at Fort Irwin did not include the extensive use of this area for force-on-force training because the areas to the north largely accommodated the Army's needs. After the listing of the desert tortoise in 1989, the Army did not conduct force-on-force training in the area south of the UTM 90 line, which generally represented the area that it had not used extensively in the past. When the Service designated critical habitat for the desert tortoise in 1994, it used the UTM 90 line as the general northern edge of critical habitat.

The Service's (2012e) biological opinion on the use of additional training lands at Fort Irwin included consideration of the southern expansion area as an area that would be used for force-on-force training and other training activities. In that biological opinion, the Service stated that: "The intensity of disturbance resulting from force-on-force training would be such that most of the primary constituent elements would not be functional for decades after training in those areas ceases."

In general, we expect that the condition of the primary constituent elements within the western expansion area and the Goldstone Deep Space Communications Complex is similar to that within the remainder of the Superior-Cronese Critical Habitat Unit. That is, although we expect that the first, third, fourth, and fifth primary constituent elements have been affected to some degree by human activities, these impacts have not, to date, substantially compromised the conservation value and function of the critical habitat. We expect that invasive plants have compromised the conservation value and function of critical habitat to some degree with regard to the second primary constituent element (i.e., sufficient quality and quantity of forage species and the proper soil conditions to provide for the growth of these species). Because most of the critical habitat within these areas experiences fewer disturbances than public lands off base, we expect that the sixth primary constituent element (i.e., habitat protected from disturbance and human caused mortality) has not been appreciably affected by human activities. We expect that force-on-force training will eventually cause severe degradation of the primary constituent elements of critical habitat within the southern expansion area.

EFFECTS OF THE ACTION

As we described in the Description of the Proposed Action section of this biological opinion, the Army and Service evaluated each of the Army's proposed activities and listed the aspects of the activity that may affect desert tortoises or their habitat (including critical habitat). See the following table.

DRAFT **DRAFT** **DRAFT**

Activities Associated with the Proposed Action and Potential Effects on Desert Tortoises and Their Critical Habitat										
		Driving off Road	**Driving on Road**	**Ground Distur-bance**	**Explosions (potential for fire)**	**Non-native Plants**	**Common Ravens**	**Moving from Harm's Way**	**Personnel on Foot**	**Habitat Conversion**
Training Area Activities	Desert tortoise	Y	Y	Y	Y	Y	Y	Y	Y	Y
	Critical Habitat	N/A								
Training Area Management /Safety Activities	Desert tortoise	Y	Y	Y	Y	Y	Y	Y	Y	Y
	Critical Habitat	Y	Y	Y	N	Y	N	N	N	Y
Alternative Energy Development	Desert tortoise	Y	Y	Y	N	N	Y	Y	Y	Y
	Critical Habitat	N/A								
Research and Education	Desert tortoise	Y	Y	Y	N	N	N	Y	Y	N
	Critical Habitat	Y	N	Y	N	Y	N	N	N	N
Recreation and Related Activities	Desert tortoise	Y	Y	Y	N	Y	Y	Y	Y	N
	Critical Habitat	N	N	N	N	N	N	N	N	N
Cantonment Infrastruct-ure Activities	Desert tortoise	Y	Y	Y	N	Y	Y	Y	Y	Y
	Critical Habitat	N/A								
Y = Associated activity may affect the desert tortoise or its critical habitat in this manner. (Activities would affect critical habitat and habitat not designated as critical in the same basic manner; however, we do not consider effects to non-critical habitat in assessing whether a proposed action is likely to destroy or adversely modify critical habitat.)										
N = Associated activity does not affect the desert tortoise or its critical habitat.										
N/A = Associated activity does not occur in area of concern (desert tortoise habitat or critical habitat).										

In this section of the analysis, we will provide a general description of how these various aspects affect desert tortoises and their habitat (including critical habitat). After we review the general mechanisms of how the Army's activities may affect desert tortoise and their critical habitat, we

will analyze the potential effects of the injury or death of up to five desert tortoises per year and the loss of critical habitat. The Army and Service developed the threshold of five desert tortoises upon which to base the analysis of future activities in this biological opinion and to provide a trigger for the re-initiation of formal consultation.

Desert tortoises less than 180 millimeters in length (including hatchlings and eggs) are difficult to detect. Surveyors are less likely to detect them than desert tortoises greater than 180 millimeters because they can take shelter in smaller burrows and are more difficult to see due to their cryptic nature and their small size. Consequently, we expect that most hatchlings and eggs likely remain in work areas that have been cleared of larger desert tortoises; we expect that some desert tortoises closer to 180 millimeters in length would be detected and moved from harm's way. We anticipate that future activities are likely to result in injury or mortality of small (i.e., less than 180 millimeters in length) desert tortoises because they are more difficult to detect. Because of their cryptic nature and small size, these mortalities have potential to go undetected. We acknowledge that smaller desert tortoises and eggs may be killed during the implementation of the Army's activities; however, because they are difficult to detect and because larger individuals are more important for the long-term conservation of the species, we focused our analysis on larger individuals.

As described in the Analytical Framework for the Jeopardy and Adverse Modification Determinations - Jeopardy Determination section of this biological opinion, we have based the analysis in this biological opinion on the conditions as they now exist within Fort Irwin. Specifically, desert tortoises are uncommon in areas that have been historically used for force-on-force training and have been essentially removed from the southern expansion area as a result of preparing this area for training. The fence that the Army placed between the southern expansion area and the on-base conservation areas and land managed by the Bureau generally to the south of Fort Irwin will prevent desert tortoises from re-inhabiting training areas on base. Floods, accumulation of sand, and vandalism can compromise fences that are intended to exclude desert tortoises from an area. If the fence along the southern portion of Fort Irwin is breached, desert tortoises may re-enter the installation and alter the environmental baseline upon which we based this biological opinion. At such point in time, the Army would be required to re-initiate formal consultation with the Service, pursuant to the implementing regulations of section 7(a)(2) of the Endangered Species Act (50 Code of Federal Regulations 402.16).

Driving Off Roads

Desert Tortoise

In general, the use of vehicles off of roads (paved or unpaved) can injure or kill desert tortoises; vehicles traveling off road can also crush desert tortoise burrows trapping individuals in their collapsed burrows. In general, the Army's training activities have greatly reduced the number of desert tortoises in areas that are easily accessed by vehicles; additionally, the Army has translocated most, if not all, of the desert tortoises from the southern expansion area. In these areas, we expect that the Army's future activities are likely to kill or injure few desert tortoises because of the low numbers of animals present and because the Army will implement measures

during the implementation of its activities to protect desert tortoises during the use of vehicles off road.

Desert tortoises are likely more common is areas where vehicles are less likely to travel, such as areas that are steep and rugged or that have no value for training. The greater number of desert tortoises in these areas increases the risk of injury or mortality to some degree; however, we do not expect that the Army would use these areas as frequently and it would implement protective measures during such use. Consequently, we expect that use of vehicles off road in these areas is also likely to injure or kill few desert tortoises.

Critical Habitat

In general, the use of vehicles off of roads (paved or unpaved) can destroy plants needed for cover and food, erode and compact substrates, cause proliferation of weeds, and increase in the number and location of wildfires. We do not expect that the use of vehicles off of roads, at the extent likely to be conducted by the Army, would have a measurable effect on the first primary constituent element of critical habitat (sufficient space to support viable populations within each of the six recovery units and to provide for movement, dispersal, and gene flow). We have reached this conclusion because the Army's use would be relatively infrequent and monitored to the extent that it would not reduce the amount of habitat within critical habitat and prevent movement, dispersal, and gene flow.

The second through fifth primary constituent elements (sufficient quality and quantity of forage species and the proper soil conditions to provide for the growth of these species; suitable substrates for burrowing, nesting, and overwintering; burrows, caliche caves, and other shelter sites; sufficient vegetation for shelter from temperature extremes and predators) are related to the biological and physical aspects of critical habitat. We expect the low level of use of vehicles off roads, which will be appropriately monitored, would not affect the function of these aspects of the desert tortoise's habitat in a measurable manner.

This aspect of the Army's activities would minimally affect the sixth primary constituent element (habitat protected from disturbance and human caused mortality) because it would occur infrequently and be monitored.

Driving on Roads

Desert Tortoise

Desert tortoises are generally more easily observed on roads, because of their more even surfaces and lack of plant cover. Roads often allow vehicles to travel at higher speeds, which reduce the likelihood of drivers detecting and avoiding desert tortoises. Rises and turns in roads also decrease the ability of drivers to detect desert tortoises. Along heavily used roads, the number of desert tortoises is depressed for some distance from the edge of the road as a result of road-associated mortality; this distance varies with the level of use of the road. In general, vehicle use is likely to result in at least some mortalities of and injuries to desert tortoises; the extent of the loss is related to the condition of the road, the time of the year when vehicle use occurs, the

abundance of desert tortoises, and the awareness of the driver. Even the most careful drivers may occasionally strike a desert tortoise.

The Army addresses this threat in its protective measures by posting signs for reduced speed limits where appropriate. Additionally, all personnel who travel in desert tortoise habitat at Fort Irwin are briefed so that they are aware of the potential presence of desert tortoises on roads. We expect this threat to persist throughout the action area.

Critical Habitat

The use of existing roads will not affect the second through fifth primary constituent elements because these physical and biological aspects of critical habitat are no longer present within roads. Roads that experience high levels of traffic can essentially form a barrier to movement, dispersal, and gene flow (first primary constituent element); the only road within Fort Irwin that likely experiences this level of traffic is Fort Irwin Road, which connects the cantonment area to Barstow. High levels of traffic may affect the sixth primary constituent element (habitat protected from disturbance and human caused mortality) by increasing the number of desert tortoises that are injured or killed. At least portions of the desert tortoise habitat adjacent to Fort Irwin Road are heavily used for training and other activities; desert tortoises are likely less common in these degraded areas and therefore less likely to enter the road.

Ground Disturbance

Desert Tortoise

We consider ground disturbance to include any activity where the Army's activities disrupt vegetation and substrate through the use of heavy equipment and materials. Desert tortoises may be injured or killed or trapped in their burrows during these activities. Some of the Army's activities may cause negligible amounts of ground disturbance. Conversely, the construction of a new target or building may result in ground disturbance over a larger area.

Because the Army would use standard and successful measures and experienced staff to avoid injuring or killing desert tortoises during ground-disturbing activities, we expect that relatively few individuals are likely to be injured or killed as a result of ground disturbance.

Critical Habitat

Ground disturbance has the potential to adversely affect all the primary constituent elements of critical habitat. Small amounts of ground disturbance that are temporary in nature would generally affect critical habitat less than larger areas of permanent disturbance, although some indirect effects of smaller projects (e.g., the proliferation of weeds) can extend well beyond the temporal and spatial footprint of a project.

Explosions

Desert Tortoise

Ordnance or other materials associated with explosions could strike a desert tortoise directly. Such events are likely extremely rare, given the large area of the target sites, the sparse distribution of desert tortoises, and the relatively small area that the explosion would affect. Some potential exists that explosions can cause vibrations that would cause nearby burrows to collapse and trap desert tortoises inside.

Desert tortoises may be injured by noise associated with explosions. Bowles et al. (1999) found that subsonic and supersonic aircraft noise did not elicit substantial responses from desert tortoises. If a desert tortoise were close to a large explosion, however, we expect that the noise would have the potential to cause physical damage to the animal. Few desert tortoises are likely to be injured or killed by explosions, primarily because the areas used for such training are relatively limited in area and because of the overall low density of desert tortoises.

The integrated natural resources management plan Army (2006-2011) notes that the gunnery ranges at Fort Irwin experience frequent fires. Therefore, we will consider the~~s~~se fires as a likely effect of explosions. Fires can injure or kill desert tortoises that are away from their burrows; the use of fire equipment to fight fires could also kill desert tortoises. Larger fires during times of the year and day when desert tortoises are active are more likely to injure or kill desert tortoises than smaller fires when desert tortoises are inactive (i.e., in their burrows). Desert tortoises are less likely to be present in areas that have repeatedly burned, where non-native grasses predominate; to the extent that at least some fires occur in such areas, the risk of desert tortoises being injured or killed by fire is somewhat reduced.

The integrated natural resources management plan notes that the Army responds rapidly to fires to suppress them as quickly as possible. The Army's fire management measures are likely to reduce the potential for fires started at gunnery ranges. This measure is protective of desert tortoises because fires can kill desert tortoises that may be above ground.

Critical Habitat

The Army's use of explosives would not directly impair the value and function of critical habitat with regard to the first primary constituent element (sufficient space to support viable populations within each of the six recovery units and to provide for movement, dispersal, and gene flow). We have reached this conclusion because the explosions occur in relatively small areas that are used repeatedly. Most explosions would likely occur in areas that have been previously used for such work. However, if a large fire spread from target sites, the potential exists that habitat conditions could be altered to the extent that desert tortoises would no longer traverse such areas.

Large explosions would likely alter the quality and quantity of forage species and the soil conditions to provide for the growth of these species in new target areas (the second primary constituent element); target areas that have been used previously likely no longer support these features. Smaller explosions likely have little or no direct effect on this primary constituent element. As we previously discussed, fire spreading from a target area would likely reduce the value and function of this primary constituent element.

Large explosions likely damage substrates for burrowing, nesting, and overwintering (third primary constituent element) and burrows, caliche caves, and other shelter sites (fourth primary constituent element). Because most explosions would occur in previously used, defined target areas, damage to substrates and shelter sites is likely to be minimal. Fire may affect substrates and shelter sites if it removes sufficient plant cover to increase erosion during storm events. Large explosions would remove vegetation that desert tortoises use for shelter from temperature extremes and predators (the fifth primary constituent element), but generally in a limited area. This adverse effect would be reduced by the use of existing target sites. Fire would affect shelter sites provided by shrubs if it spreads beyond the disturbed target site.

The repeated use of target sites would reduce the potential for explosions to have a measurable effect on the sixth primary constituent element (habitat protected from disturbance and human-caused mortality) because the disturbance and potential for mortality of desert tortoises would be limited to a relatively small portion of critical habitat. Conversely, the creation of new bombing targets in critical habitat would require the Army to clear additional lands. As with the other primary constituent elements, fire that spreads beyond disturbed areas around the target sites would increase the adverse effect.

The Army's fire management measures likely reduce the potential that fires started at target sites would have a measurable effect on the primary constituent elements of critical habitat of the desert tortoise. The goal of the integrated natural resources management plan is to protect lands and natural resources from wild fires. This goal is protective of the primary constituent elements of critical habitat. In the event of a wildfire that may affect desert tortoises or their critical habitat, the Army and Service would consult under the emergency provisions of section 7(a)(2) of the Endangered Species Act.

Non-native Plant Species

Desert Tortoise

Vehicles, ground disturbance, fire, and other human activities contribute to the dispersal of non-native plant species. These non-native plants include species that are already present in the California desert and newly introduced species. As we discussed in the Status of the Species and Critical Habitat section of this biological opinion, non-native plants can alter the quality and quantity of plant foods available to desert tortoises and thereby affect their nutritional intake.

Critical Habitat

The spread of non-native plant species may impair the value and function of the first primary constituent element (sufficient space to support viable populations within each of the six recovery units and to provide for movement, dispersal, and gene flow) if they become so widespread and dense that they reduce the ability of desert tortoises to forage over wide areas. This threat is most prominent in the action area where fires have the potential to alter habitat conditions on a large scale.

As we discussed in the Status of Critical Habitat of the Desert Tortoise section of this biological opinion, the function and value of the second primary constituent element (sufficient quality and quantity of forage species and the proper soil conditions to provide for the growth of these species) have been compromised to some degree throughout the range of the desert tortoise. The Army's activities, particularly near targets where fires are more likely, may exacerbate this threat.

The spread of non-native plant species is not likely to affect the third and fourth primary constituent element (suitable substrates for burrowing, nesting, and overwintering; burrows, caliche caves, and other shelter sites). We have reached this conclusion because the plants would not generally affect substrates or shelter sites used by desert tortoises.

Non-native plant species can degrade vegetation that desert tortoises use to seek shelter from temperature extremes and predators (the fifth primary constituent element), primarily by supporting larger and more intense fires. Most shrubs in the California desert are not adapted to fire. Once fire kills these shrubs, they are unlikely to return, thus depriving desert tortoises of shelter sites.

Habitat that is degraded by the presence of a large component of non-native species has not been protected from disturbance and human-caused mortality (the sixth primary constituent element). Consequently, spread of non-native plant species has the potential to further degrade the value and function of this primary constituent element.

As we discussed in the Status of the Desert Tortoise section of this biological opinion, current information indicates that invasive species likely affect a large portion of the desert tortoise's range. Non-native species can occur in densities that can increase the risk of fires, which, in turn, destroy native species and may result in future habitat loss. We expect that the non-native plant species routinely found in the Mojave Desert occur throughout Fort Irwin.

The Army's goal with regard to non-native plant species is to "control noxious and invasive exotic plants to support the military mission, promote sustained ecosystem functionality, favor native species biodiversity, and add to the quality of life" at Fort Irwin (Army 2006-2011). This goal is protective of critical habitat of the desert tortoise.

Common Ravens

Desert Tortoise

The Army has proposed to manage its trash and debris to reduce the attractiveness of Fort Irwin to common ravens. This protective measure would likely be effective in reducing some level of food subsidies to common ravens. We expect that buildings and other structures on Fort Irwin would continue to provide common ravens with more perching, roosting, and nesting sites than would be found in a natural setting. We also expect that common ravens ~~also~~ derive at least some food and water from the residential area of the installation. Future development may lead to an increase in the number of people using the residential area, which may, in turn, increase the amount of food and water available to common ravens. Any increase in the number of common

ravens would likely result in increased predation of desert tortoises.

Critical Habitat

Common ravens do not affect the primary constituent elements of critical habitat.

Moving Desert Tortoises from Harm's Way

Desert Tortoise

Biologists considered translocation to be an ineffective tool in reducing the impacts of projects on desert tortoises and raised concerns regarding its numerous potential adverse effects (e.g., overcrowding, increased disease transmission, increased mortality, elevation of stress hormones, vulnerability to drought, etc.). Over the past approximately 10 years, several researchers (including several studies funded by the Army at Fort Irwin) have undertaken studies to more carefully evaluate the effects of translocation on desert tortoises; some of these studies have included the monitoring of control and resident animals. (Desert tortoises used as controls inhabit areas that are disjunct from those occupied by translocated animals; resident animals occupy areas into which desert tortoises have been translocated.) These studies have indicated that translocated, resident, and control animals do not have significant differences in mortality rates or in levels of stress hormones. The reproductive output of translocated animals is slightly lower than that of residents or controls for the first year after translocation and translocated animals tend to move more but settle down after a period of time.

The Service's (2013) biological opinion for the Stateline and Silver State South solar projects contains an~~d~~ extensive discussion of the potential effects of translocation on desert tortoises; we incorporate that analysis herein by reference. Because of the results of the studies on translocation, we expect that the movement of desert tortoises from harm's way during the Army's activities is likely to have a negligible effect on these individuals. The potential exists that a small number of translocated or resident desert tortoises may die or be injured during the translocation because of the specific circumstances; however, we consider this likelihood.to be low.

Comment [c12]: Since we are discussing moving tortoises out of harm's way, the majority of these animals will be moved a short distance by a biologist on foot, does this sentence make sense? It seems to be discussing something different than what is described in the next paragrapyh.

Critical Habitat

Moving desert tortoises from harm's way will not affect critical habitat because this activity primarily involves the transport of individuals a relatively short distance by a biologist who is traveling on foot. Neither the desert tortoises themselves nor the personnel who transport them will affect the primary constituent elements of critical habitat. The construction of artificial burrows would disturb limited areas where annual plants could grow and their supporting substrates; however, this disturbance will not measurably affect the value or function of the primary constituent elements of critical habitat.

Personnel on Foot

Desert Tortoise

Because of their small size, hatchlings and slightly larger desert tortoises could be trampled by foot traffic. Nests are also vulnerable, but their typical location, near the mouth of a burrow, likely protects them to some degree.

We expect that few desert tortoises would be injured or killed in this manner because most Army personnel working in desert tortoise habitat will receive specific training, which would increase their awareness of this potential threat. Additionally, we expect that the likelihood of stepping on desert tortoises would generally be low because most activities involving personnel on foot would occur in a relatively limited area of the base and most frequently in situations where the Army has conducted surveys to protect desert tortoises.

Critical Habitat

This activity will not affect the primary constituent elements of critical habitat because of the general low intensity of use.

Habitat Conversion

Desert Tortoise

Various activities that the Army may undertake have the potential to cause habitat conversion. The act of converting habitat from an area that is suitable for desert tortoises into some other environment has the potential to kill the individuals living in that area. Generally, the heavy equipment that is involved in the conversion of habitat would crush any desert tortoises that are present.

As we have discussed previously in this biological opinion, other factors, such as fire and an overabundance of non-native species can, either together or separately, convert an area of suitable habitat for desert tortoises into something that is far less able to support them. Over time, desert tortoises that are forced to live in such areas are likely to die as a result of starvation; prior to that, their reproductive output would likely be lower because of their poorer physiological condition.

Critical Habitat

Suitable habitat generally is that which contains the primary constituent elements of critical habitat in a functioning condition. In the context of critical habitat, habitat conversion would occur when the amount of disturbance or alteration of a primary constituent element removes its function or value. Any ground-based activity that the Army undertakes could potentially disturb or alter, to some degree, the primary constituent elements. As examples, the extensive use of off-road vehicles could decrease the amount of space needed to support a viable population of desert tortoises and to provide for movement, dispersal, and gene flow within the Western Mojave Recovery Unit. Vehicles traveling off roads could decrease the quality and quantity of forage species and the substrate conditions that support the growth of these species and for burrowing; off-road travel could also destroy burrows, caliche caves, and other shelter sites and

the perennial vegetation that desert tortoises use for shelter from temperature extremes and predators. Off-road vehicle use would increase the amount of disturbance and human-caused mortality in the area in which it occurred.

CUMULATIVE EFFECTS

Cumulative effects include the effects of future State, tribal, local or private actions that are reasonably certain to occur in the action area considered in this biological opinion. Future Federal actions that are unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to section 7 of the Act. Most of the action area is entirely located within Fort Irwin and is therefore on Federal lands; any future actions will be subject to the consultation requirements of section 7(a)(2) of the Act. The only portion of the action area that is not within Fort Irwin is the Manix Trail. Most of the route traverses lands managed by the Bureau, which is also subject to the consultation requirements of section 7(a)(2) of the Act. Portions of the Manix Trail cross non-federal lands; however, we are unaware of any non-federal actions that are reasonably certain to occur in this area.

CONCLUSION

Desert Tortoise

The regulatory definition of "to jeopardize the continued existence of the species" focuses on assessing the effects of the proposed action on the reproduction, numbers, or distribution of the species being considered in the biological opinion. For that reason, we have used those aspects of the desert tortoise's status as the basis to assess the overall effect of the proposed action on the species.

In the first portion of the Effects of the Action section of this biological opinion, we provided a general description of how the various activities that the Army expects to undertake are likely to affect desert tortoises. In the following sections, we will use the proposed re-initiation threshold of five desert tortoises killed in a year to determine how the future operation of Fort Irwin would affect the reproduction, number, and distribution of the desert tortoise. We will then assess the effects of the proposed action on the recovery of the species and whether it is likely to appreciably reduce the likelihood of both the survival and recovery of the desert tortoise. We reach our conclusion regarding whether an action is likely "to jeopardize the continued existence of the species" through an analysis of how a proposed action affects the listed taxon within the action area in relation to the range of the entire listed taxon. For the desert tortoise, this process involves considering the effects at the level of the action area, then at the level of the recovery unit (in this case, the Western Mojave Recovery Unit), and then finally for the range of the listed taxon. Logically, if an aspect of the proposed action is unlikely to cause a measurable effect within the action area, it is unlikely to affect the recovery unit or the remainder of the range.

<u>Reproduction</u>

The reproductive output of individuals of a species is determined in part by the species' breeding ecology, overall abundance of breeding individuals, and the condition of the habitat in which

they live. The reproductive output of the desert tortoise is governed by several aspects of its breeding ecology: the delayed onset of breeding, many years of reproduction, high mortality rates of eggs and young, and low mortality rates among adults. If the population of desert tortoises at Fort Irwin was stable or increasing, the loss of five individuals per year to human activities would be unlikely to have a measurable effect on its overall reproductive capacity. The long reproductive life of female desert tortoises and the normally low mortality rates among adult animals are factors that would protect the reproductive output of a population.

The overall abundance of breeding individuals would also influence how the loss of five desert tortoises per year affects their reproductive output at Fort Irwin. In general, desert tortoises occur at low densities in most areas of the base. In some areas, their densities are extremely low. The effects of the mortality of five desert tortoises per year within Fort Irwin may negatively affect the amount of reproduction for several reasons. First, the loss of even a small number of individuals in a low-density population could render finding mates more difficult. Second, desert tortoises require from 13 to 20 years to reach sexual maturity. Third, females produce a relatively small number of eggs per year. Fourth, desert tortoises also experience high mortality early in life (including as eggs). Consequently, even moderate downward fluctuations in adult survival rates can result in rapid population declines; slow reproductive rates and high juvenile mortality limit the capacity of populations to increase rapidly after a decline (Service 2011).

The desert tortoise possesses two safeguards against the loss of reproduction in areas of low population density. First, female desert tortoises can store sperm for several years; this trait provides some hedge against low densities precluding reproduction because females do not need to encounter males every year to produce young. Second, breeding-age desert tortoises would continue to produce young over their long reproductive life; this reproductive output could replace individuals that are killed by the Army's activities.

The amount and timing of rainfall in the desert greatly influences the production of native annual plants upon which desert tortoises feed. A high diversity and abundance of annual plants provide desert tortoises with the appropriate quality and quantity of food to persist and to produce eggs. The widespread invasion of non-native annual plants has likely reduced the desert tortoise's ability to obtain the appropriate quality and quantity of forage plants on a consistent basis. Human disturbance of substrates and increased frequency of fires render desert habitat more susceptible to invasion by non-native annual plants. The potential exists that non-native plants are already established at Fort Irwin to the degree that the Army's activities would not exacerbate the situation. The Army's program to manage non-native plants is unlikely to substantially alter the flora of Fort Irwin to one that is predominantly native species; conversely, it is likely to prevent the spread of new weeds throughout the base. If the Army introduced new species of invasive plants during its activities or expanded the area of infestation of invasive species already on base, the quality of desert tortoise habitat would likely further decrease; such a decrease would negatively affect the ability of Fort Irwin to support the reproduction of desert tortoises at the highest levels of productivity.

Based on these factors, we conclude that the loss of five individuals per year to the Army's activities is likely to cause a minor depression of reproduction of desert tortoises at Fort Irwin. We acknowledge that all five individuals may not be of reproductive age; the loss of non-

reproductive individuals would not have an immediate effect on reproduction. We also acknowledge that the loss of younger animals would reduce their potential recruitment into breeding age individuals.

Our determination with regard to whether a proposed action is likely to jeopardize the continued existence of a species is based on the status of the listed taxon throughout its range and not just within the action area. Consequently, although the loss of five individuals per year at Fort Irwin is likely to cause a minor depression of reproduction of desert tortoises at Fort Irwin, this loss is unlikely to have a measurable effect on the reproduction of desert tortoises within the Western Mojave Recovery Unit or range wide. We have reached this conclusion because Fort Irwin supports a small portion of the estimated number of desert tortoises that occur within the Western Mojave Recovery Unit and an even smaller portion of the number within the species' range. The next section of this analysis provides insight into the numbers of desert tortoises within Fort Irwin, the Western Mojave Recovery Unit, and range wide.

Number

We used the estimate provided by the Desert Tortoise Recovery Office (2014) to assess how the loss of five individuals per year at Fort Irwin would affect the desert tortoise, first within the Western Mojave Recovery Unit (where Fort Irwin is located) and then throughout its range. The numbers in the following table are based on desert tortoises that are greater than 180 millimeters and are based on sampling conducted within desert tortoise conservation areas where densities may be greater than they are outside of these areas. To provide a longer perspective of how the loss of 5 individuals per year may affect the population of desert tortoises over time, we have included a cumulative loss of 100 individuals (i.e., 5 desert tortoises each year for 20 years of activities) in the table.

Number of Desert Tortoises Killed	**Percentage of Annual Mortality Estimate Compared to Overall Population**	
	Western Mojave Recovery Unit 76,323	**Range-wide 106,000**
Year 1 - 5	0.0065	0.0047
Year 20 - 100	0.1310	0.0943

We acknowledge that we cannot predict whether the numbers of desert tortoises at Fort Irwin, within the Western Mojave Recovery Unit, or range wide would change over the next 20 years. We expect the overall factors that affect the status of desert tortoises to be similar within and outside Fort Irwin. If the number of desert tortoises at Fort Irwin decreases, we expect that the Army would encounter fewer individuals while it is implementing actions and, therefore, fewer individuals are likelier to die. If more desert tortoises ~~number~~ occur at Fort Irwin in the future, the risk that desert tortoises would die at any given project would increase but the Army's proposed protective measures (including a commitment to re-initiate formal consultation if five are killed in a year) would prevent an appreciable increase in mortalities.

Consequently, based on the best available information, we conclude that the loss of five desert tortoises per year is not likely to appreciably diminish the number of desert tortoises, either

within the Western Mojave Recovery Unit or range wide.

We did not discuss the injury of desert tortoises in this section. The implementing regulations for section 7 of the Endangered Species Act at 50 Code of Federal Regulations 402.14(i)(1)(iv) require the Service to specify the procedures to be used to handle or dispose of any individuals of a species that is killed or injured during the implementation of a proposed action that has undergone formal consultation. Consequently, in the Incidental Take Statement - Disposition of Dead or Injured Specimens section of this biological opinion, we will direct the Army to take injured desert tortoises to a qualified veterinarian for treatment and to contact us regarding the final disposition ~~any~~of these animals. If they recover from their injuries to the extent that they can be released to the wild, these animals would not be included in the annual count of dead desert tortoises.

Distribution

With the exception of the consultations in which the Service analyzed the effects of training on desert tortoises, previous consultations with the Army generally involved numerous actions that affected scattered, relatively small areas of desert tortoise habitat across Fort Irwin. We expect this general pattern to continue. One exception is the Army's proposal to allow for the development and operation of solar plants within Fort Irwin. We are aware that solar plants may occupy up to several thousand acres.

In its biological opinion on the use of additional maneuver training lands at Fort Irwin, the Service (2012) concluded th~~eat~~ proposed action was not likely to appreciably diminish the distribution of the desert tortoise in the Western Mojave Recovery Unit. In that biological opinion, the Service noted that the desert tortoise was near the northern edge of its range in this portion of the Mojave Desert and that the region north of the southern expansion area supported relatively few desert tortoises because of past training.

Future development at Fort Irwin, including solar plants, would reduce the amount of habitat on base and increase, to some degree, the amount of fragmentation on a local scale. Most of the activities associated with infrastructure improvements and the development of solar plants would occur within the boundaries of Fort Irwin as they existed prior to the recent expansion. Desert tortoises have been virtually extirpated within Fort Irwin north of the southern expansion area and occur in low densities, if they occur at all, within the southernmost portion of Death Valley National Park, which lies to the north of Fort Irwin; these animals are few in number and likely already isolated from the remainder of the population in the Western Mojave Recovery Unit, at least across the existing training areas of Fort Irwin.

Little, if any, development would occur in the western expansion area or on the Eastgate parcel. The Army will not undertake substantial activities in the western expansion area until it determines its future training needs, at which time it would re-initiate formal consultation with the Service. The Eastgate parcel is generally too steep and far removed from the cantonment area to support large-scale development.

For these reasons, we have concluded that future development at Fort Irwin would not

appreciably diminish the distribution of the desert tortoise within the Western Mojave Recovery Unit.

Effects on Recovery

Fort Irwin occupies a relatively small portion of the Western Mojave Recovery Unit and an even smaller portion of the range of the desert tortoise. Consequently, the activities that the Army conducts on base under consideration in this biological opinion are unlikely to have an appreciable direct effect on the recovery of the desert tortoise. The relatively small number of desert tortoises that we expect the Army to kill annually is unlikely to appreciably diminish the ability of the desert tortoise to reach stable or increasing population trends in the future.

After reviewing its current status, the environmental baseline for the action area, the effects of the proposed action, and the cumulative effects, it is the Service's biological opinion that the proposed action is not likely to jeopardize the continued existence of the desert tortoise. We have reached this conclusion for the following reasons. First, the Army's activities are unlikely to affect the reproductive capacity of desert tortoises within Fort Irwin. Second, the few desert tortoises that the Army is likely to kill comprise a minor fraction of the number of desert tortoises within the Western Mojave Recovery Unit and range-wide. Third, future development within Fort Irwin would not appreciably diminish the distribution of the desert tortoise within the Western Mojave Recovery Unit or range-wide. Fourth, the Army's activities within Fort Irwin are not likely to have a measurable effect on the recovery of the desert tortoise.

Critical Habitat of the Desert Tortoise

Critical habitat of the desert tortoise occurs in three portions of Fort Irwin: the southern expansion area, the western expansion area, and the Goldstone Deep Space Communications Complex. In its biological opinion on the use of additional maneuver training lands at Fort Irwin, the Service (2012) concluded that training activities, such as force-on-force maneuvers and the construction of sites for military operations in urban terrain, would disturb 18,197 acres of critical habitat in the southern expansion area. We concluded that this area would no longer support the conservation values and function of critical habitat within the Superior-Cronese Critical Habitat Unit. The effects of the actions considered in this biological opinion are likely to be somewhat different than those in the 2012 document. That is, the Army's proposed actions would occur in an area that the Service has already determined had lost the conservation value and function of critical habitat; therefore, we will not consider future development by the Army in the southern expansion area to affect the baseline conditions of critical habitat. Even considering the disturbance of 18,197 acres within the southern expansion area, the Superior-Cronese Critical Habitat Unit includes approximately 5,699,681 acres of modeled critical habitat.

The Army would not engage in any large-scale development in the western expansion area; activities in that area would mostly be limited to general maintenance actions, such as repair of the fence around this area and of other existing facilities. Such activities would disturb a small portion of the 70,549 acres of critical habitat within the western expansion area.

The Goldstone Deep Space Communications Complex includes 4,284 acres of critical habitat

(Everly 2014). As with the western expansion area, the Army would limit its activities to general maintenance actions in this area. Such activities would disturb a small portion of the critical habitat within the Goldstone Deep Space Communications Complex.

After reviewing the current status of critical habitat, the environmental baseline for the action area, the effects of the proposed action, and the cumulative effects, it is the Service's biological opinion that the proposed action is not likely to result in the destruction or adverse modification of critical habitat of the desert tortoise. We have reached this conclusion because the small amount of disturbance of critical habitat we anticipate within the western expansion area and Goldstone Deep Space Communications Complex would comprise a negligible portion of the approximately 5,699,681 acres of modeled critical habitat remaining in the Superior-Cronese Critical Habitat Unit and an even smaller portion of critical habitat range wide. Therefore, the proposed action is not likely to affect the conservation value and function of critical habitat.

INCIDENTAL TAKE STATEMENT

Section 9 of the Act and Federal regulation pursuant to section 4(d) of the Act prohibit the take of endangered and threatened wildlife species, respectively, without special exemption. Take is defined as to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or to attempt to engage in any such conduct. Harm is further defined by the Service to include significant habitat modification or degradation that results in death or injury to listed species by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering. Harass is defined by the Service as an intentional or negligent act or omission which creates the likelihood of injury to wildlife by annoying it to such an extent as to significantly disrupt normal behavioral patterns which include, but are not limited to, breeding, feeding, or sheltering. Incidental take is defined as take that is incidental to, and not the purpose of, the carrying out of an otherwise lawful activity. Under the terms of section 7(b)(4) and section 7(o)(2), taking that is incidental to, and not the purpose of, the agency action is not considered to be prohibited taking under the Act provided that such taking is in compliance with the terms and conditions of this incidental take statement and the avoidance and minimization measures proposed by the Army.

The measures described below are non-discretionary; the Army must implement these measures during the conduct of its activities or include them as binding conditions of any grant or permit issued to its customers and contractors, as appropriate, for the exemption in section 7(o)(2) to apply. The Army has a continuing duty to regulate the activity covered by this incidental take statement. If the Army fails to assume and implement the terms and conditions or fails to require its customers and contractors to adhere to the terms and conditions of the incidental take statement through enforceable terms that are added to the permit or grant document, the protective coverage of section 7(o)(2) may lapse. To monitor the impact of incidental take, the Army must report the progress of the actions and its impact on the species to the Service as specified in the incidental take statement (50 Code of Federal Regulations 402.14(i)(3)).

The Service anticipates that five desert tortoises per year are likely to be taken, in the form of mortality, as a result of the operation of Fort Irwin. We derived this number through discussions with the Army and used it as the basis of our section 7(a)(2) analysis in this biological opinion. This number also serves as a basis for the re-initiation of formal consultation.

We do not expect removing desert tortoises from harm's way during the implementation of the Army's activities to result in their injury or mortality. Therefore, we are not including an anticipated amount or extent of this form of take (i.e., capture).

REASONABLE AND PRUDENT MEASURE

The Service believes the following reasonable and prudent measure is necessary and appropriate to minimize take of desert tortoises during activities related to operations and activities at Fort Irwin:

> The Army must ensure that desert tortoises do not re-enter the southern expansion area from the conservation areas and other lands adjacent to the southern expansion area.

Our evaluation of the proposed action includes consideration of the protective measures proposed by the Army and described in the Description of the Proposed Action section of this biological opinion. Consequently, any changes in these protective measures may constitute a modification of the proposed action that causes an effect to the desert tortoise that was not considered in the biological opinion and require re-initiation of consultation, pursuant to the implementing regulations of the section 7(a)(2) of the Act (50 Code of Federal Regulations 402.16).

TERMS AND CONDITIONS

To be exempt from the prohibitions of section 9 of the Act, the Army must comply with or ensure that any contractor complies with the following term and condition, which implements the reasonable and prudent measure described in the previous section of this biological opinion, and the reporting and monitoring requirements. This term and condition is discretionary.

> The following term and condition implements the reasonable and prudent measure:
>
> The Army must ensure that the fence separating the southern expansion area from its conservation areas and other adjacent lands remains intact and functional. To this end, the Army must inspect the fence regularly to determine whether it has been compromised by vandalism, blowing sand, or any other factor. The Army must also inspect the fence after any storm event that may generate flooding. When desert tortoises are active and have a greater likelihood of re-entering the southern expansion area, the Amy must effect repairs within 3 days of finding the breakage in the fence. When desert tortoises are inactive and have a lesser likelihood of re-entering the southern expansion area, the Amy must affect repairs within 7 days of finding the breakage in the fence. The Army's Natural and Cultural Resources Program Manager is responsible for determining the activity levels of desert tortoises.

REPORTING REQUIREMENTS

Pursuant to 50 Code of Federal Regulations 402.14(i)(3), the Army must provide a report to the

Service that provides details on each desert tortoise that is killed or injured by its activities. In addition to the information that the Army will provide to the Service in its annual report, as described in the Administration of the Consultation section of this biological opinion, the report must also include information on any instances when desert tortoises were killed, injured, or handled, the circumstances of such incidents, and any actions undertaken to prevent similar instances from re-occurring. The report must also include a description of the monitoring efforts that occurred during implementation of actions that occur with desert tortoise habitat.

DISPOSITION OF DEAD OR INJURED SPECIMENS

Within 3 days of locating any dead or injured desert tortoises, the Army must notify the Ventura Fish and Wildlife Office by telephone (805 644-1766) and by facsimile or electronic mail. The report must include the date, time, and location of the carcass, a photograph, cause of death, if known, and any other pertinent information.

The Army must take any injured desert tortoises to a qualified veterinarian for treatment. If any injured desert tortoises survive, the Army must contact the Service regarding their final disposition.

Care must be taken in handling dead specimens to preserve biological material in the best possible state for later analysis, if such analysis is needed. The Service will make this determination when the Army provides notice that a desert tortoise has been killed by project activities.

CONSERVATION RECOMMENDATIONS

Section 7(a)(1) of the Act directs Federal agencies to use their authorities to further the purposes of the Act by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations are discretionary agency activities to minimize or avoid adverse effects of a proposed action on listed species or critical habitat, to help implement recovery plans, or to develop information.

We recommend that the Army:

1. Assist the Service in implementation of the management plan for the common raven, control of feral dogs, management of subsidies for coyotes (*Canis latrans*), and numerous other activities that are intended to reduce the mortality levels of desert tortoises and improve habitat conditions.

2. Mark small desert tortoises from within project sites prior to their movement from harm's way or translocation. This marking would provide some information on their post-project status if they are encountered during future surveys or monitoring efforts. If the Army determines that it will include this requirement, we suggest that the authorized biologist contact the Desert Tortoise Recovery Office to ascertain the most appropriate means of marking the animals.

The Service requests notification of the implementation of any conservation recommendations so we may be kept informed of actions minimizing or avoiding adverse effects or benefitting listed species or their habitats.

RE-INITIATION NOTICE

This concludes formal consultation on operations and activities at Fort Irwin. As provided in 50 Code of Federal Regulations 402.16, re-initiation of formal consultation is required where discretionary Federal involvement or control over the action has been retained or is authorized by law and: (1) if the amount or extent of taking specified in the incidental take statement is exceeded; (2) new information reveals effects of the agency action that may affect listed species or critical habitat in a manner or to an extent not considered in this opinion; (3) the agency action is subsequently modified in a manner that causes an effect to the listed species or critical habitat not considered in this opinion; or (4) a new species is listed or critical habitat designated that may be affected by the action. In instances where the amount or extent of incidental take is exceeded, the exemption issued pursuant to section 7(o)(2) will have lapsed and any further take would be a violation of section 4(d) or 9. Consequently, we recommend that any operations causing such take cease pending re-initiation.

Sincerely,

Kennon A. Corey
Assistant Field Supervisor

APPENDICES

1. Mojave population of the desert tortoise (*Gopherus agassizii*). 5-year review: summary and evaluation. Available on disk or hard copy by request or at http://ecos.fws.gov/docs/five_year_review/doc3572.DT%205Year%20Review_FINAL.pdf.

ACKNOWLEDGEMENTS

Funding or support-in-kind was provided by Fort Irwin National Training Center, the National Park Service portion of Grand Canyon-Parashant National Monument, Joshua Tree National Park, and the Arizona Strip Office of the Bureau of Land Management.

The original design for this project and considerations for optimizing it based on new information and experience were first set out in Anderson and Burnham (1996) and Anderson et al. (2001). Estimation methods were further refined during a 2008 workshop for distance sampling held by S. Buckland, L. Thomas, T. Marques, E. Rexstad, and D. Harris in Marshall, California.

Personnel from Kiva Biological Consulting (California) led by I. Daly, from the Institute for Wildlife Studies (California and Nevada) led by N. Gregory, and from the Great Basin Institute (Nevada, Arizona, and the Beaver Dam Slope of Utah) led by T. Christopher conducted the field surveys. The field monitors from these teams and from Joshua Tree National Park who did the hard work of collecting and verifying the data were: A. Allan, L. Baierl, M. Bassett, A. Bennett, B. Benson, Z. Cava, I. Daly, A. d'Epremesnil, L. Drake, L. Driscoll, T. Faust, K. Foley, P. Fuchs, M. Grode, J. Hamner, K. Harding, M. Immel, A. Johnson, G. Johnson, S. Johnson, M. Jolliff, K. Lalumiere, D. Leach, J. Macmillan, J. MacNaughton, C. Martin, C. McClurg, C. Michaud, N. Mikle, L. Mjos, B. O'Brien, C. O'Leary, A. Paulson, T. Rode, S. Root, J. Ross, R. Salonikios, D. Sanderson, W. Schultz, J. Scott, C. Sherwood, B. Sparks, A. Sturgill, T. Sullivan, D. Summers, C. Taylor, S. Vaghini, M. Vamstad, J. Werba, K. Wickwire, D. Wolfson.

R. Patil (University of Nevada, Reno); M. Brenneman (Topoworks); J. Johnson (Arizona Exotic Animal Hospital); K. Dutcher (San Diego Zoo); J. Stegmeier and R. Parr (Las Vegas Field Office, BLM); and T. Christopher and B. Sparks (GBI) provided specialized training instruction for field crews. D. Zeliff, R. Schultz, and L. Powell (Mojave Desert Ecosystem Program) provided preseason GIS support as well as independent review and post-processing of data submitted by both field groups. R. Patil (University of Nevada, Reno) updated the electronic data-collection forms and procedures used in 2012. M. Brenneman developed GIS tools for correctly reflecting transect paths and tracking completion of assigned transects. She also developed the final databases.

DRAFT

EXECUTIVE SUMMARY

The recovery program for desert tortoises in the Mojave and Colorado deserts (USFWS, 2011a) requires range-wide, long-term monitoring to determine whether recovery goals are met. Specifically, will population trends within recovery units increase for a period of 25 years? In 1999, the Desert Tortoise Management Oversight Group endorsed the use of line distance sampling (Buckland et al., 2001) as the method for estimating range-wide desert tortoise density. From 2001 to 2005, and again from 2007 through 2012, desert tortoise populations in 4 of the 5 recovery units have been part of a coordinated, range-wide monitoring program using line distance sampling. (The Upper Virgin River Recovery Unit is monitored by Utah Division of Wildlife Resources (McLuckie et al., 2012).) The first 5 years of monitoring culminated in a summary report (USFWS, 2006) that included eleven recommendations, seven of which were tied to functioning of the monitoring program and are paraphrased here:

1. The range-wide monitoring program should continue under a formal study plan subject to scientific review.
2. Refine [line distance sampling] techniques to improve sampling efficiency and estimates of trends.
3. Evaluate the spatial scale of the monitoring program.
4. Improve training lines.
5. Evaluate the use of independent field teams to improve data consistency and quality.
6. Refine and formalize/document the QA/QC process.
7. Identify and assess options for securing continued funding for range-wide population monitoring.

This report describes the full set of quality assurance steps and final results for the 2012 monitoring effort. The above issues continue to drive review and improvement of the program, so that reporting also addresses these aspects of the annual effort. The range-wide monitoring effort is directed each year at 16 strata that will be used to describe long-term trends. Data were collected on transects by field personnel working with three different groups, Kiva Biological (10 personnel), the Institute for Wildlife Studies (11 personnel), and Great Basin Institute (26 personnel). Four personnel from Joshua Tree National Park also collected telemetry data in the Park. After an intensive, 12-day specialized training session, crews completed 631 transects (7102 km) between 13 March and 22 May. In the course of these surveys, they reported 236 live tortoises.

Training is provided each year so that field crews are familiar with the specifics of distance sampling. Training also ensures consistency between the many crews collecting data. Inexperienced crews as well as those with prior experience participated in preseason training and testing provided by the USFWS. Crews were passed after demonstrating appropriate detection

DRAFT

patterns (including detection proportion on the transect line), measurement accuracy from tortoise models to the transect line, and other skills.

Four parameter estimates contribute to final reported tortoise densities in each monitoring stratum. The basis for distance sampling is the estimation of the number of tortoises detected at increasing distances from the walked transect. As surveyors look farther from the transect centerline, they will detect fewer and fewer of the tortoises that are actually there, so describing the way detections decrease with distance allows for estimation of the proportion that were present but not detected within a given distance of the centerline. Second, an estimate is made of the proportion above ground or visible in their burrows and available to be detected on transects. Third, the first two estimates are combined with the number of tortoises encountered per kilometer walked to provide the actual density in each stratum. Finally, the proportion detected on the line must be estimated. Unless all tortoises were detected on the centerline, the density estimate must be adjusted to account for the occurrence of these additional tortoises.

Separate detection curves were used to describe the decreasing ability of each team to see tortoises that were farther from the walked transect line. These detection curves will capture any differences between teams in application of the protocol, but are mostly expected to reflect the terrain as well as the extent to which vegetation obscures the view in different parts of the range, since the curves account for tortoises that were present in the same area but not seen. Kiva crews detected 39.7% of tortoises within 14 m of the transect centerline, GBI detected 37.9% out to 21 m, and IWS detected 43.2% to 15 m. The proportion of tortoises that were visible to be counted (G_0) varied in different parts of the range, which were surveyed at different times during the spring season. Visibility was as high as 97.7% in the Coyote Springs Valley telemetry site during 2 weeks in April. During the same weeks, visibility at the Superior-Cronese telemetry sites was also very high, 93.5%. Visibility in Joshua Tree National Park during the last 2 weeks of March and first 2 of April was 94.5%. Unfortunately, during this time visibility was as low as 35.6% in Chemehuevi, and was persistently low during the usual weeks of activity in the eastern part of the range. Visibility is related to encounter rates, which combined with a lack of funds from the BLM in Nevada and California to result in few observations in the central part of the Mojave Desert. On average, crews walked 30.1 km for each tortoise that was observed, but this number varied considerably from one monitoring stratum to the next. Although densities in the Northeastern Mojave Recovery Unit had been estimated at less than 2/km^2 in some previous years, the density was estimated at 3.4/km^{2,} similar to the past 4 years. The Western and Eastern Mojave recovery units had few transects and therefore few observations in some strata; density estimates in 4 strata were based on 1 or 2 observations. These strata had extremely low density estimates which were presumably an artifact of the sampling regime but nonetheless depressed recovery-unit level density estimates as well. Note that funding commitments in California were withdrawn 2 weeks before crews were on the ground so it was not possible to alter the sampling design that was already in place.

AR060101

To enable field crews to complete transects in previously unsampled areas within strata, a set of guidelines was implemented in 2008 and 2009 for shortening transects in areas with rugged terrain or other obstacles (USFWS 2012a). These rules did enable crews to sample entire strata in a more representative way; however, in areas of California with lower funding, the resulting substrata never had enough transects or tortoise observations to separately evaluate tortoise densities in flat compared to rugged terrain. For this reason, in 2010, a more relaxed protocol was implemented in California, under which transects were to be completed to the extent possible along the original 12 km path. Mountainous terrain in the path was circumnavigated without searching for tortoises, then the path was resumed when possible. This method samples walkable areas representatively and also allows the proportion of unwalkable terrain to be estimated; in 2012 it was implemented throughout the range. Our density estimates are applicable to the estimated 88.3% of terrain in critical habitat and other areas managed for tortoises that is also walkable.

DRAFT

RANGE-WIDE MONITORING OF THE MOJAVE DESERT TORTOISE
2012

INTRODUCTION

The Mojave Desert population of the desert tortoise (*Gopherus agassizii*) was listed as threatened under the Endangered Species Act in 1990. This group of desert tortoises north and west of the Colorado River are now recognized as the species *G. agassizii*, separate from *G. morafkai* south and east of the Colorado River (Murphy et al., 2011). The revised recovery plan (USFWS, 2011a) designates five recovery units and to which decisions about continued listing status should be applied. The recovery plan specifies that consideration of delisting should only proceed when populations in each recovery unit have increased for at least one tortoise generation (25 years), and the only means to determine trend is by a rigorous program of long-term monitoring. Before the tortoise was listed, populations were monitored either using strip transects (Luckenbach, 1982) where indications of tortoise presence (live or dead tortoises, scats, burrows, or tracks) were converted to tortoise abundance categories based on calibration transects conducted in areas of better-known tortoise density, or by using capture-recapture population estimates on a limited number of (usually) 1-mi^2 study plots (Berry and Nicholson, 1984). Although data have continued to be collected on transects and study plots in recent years, these methods suffer statistical deficiencies and/or logistical constraints that render them unsuited for monitoring trends in abundance applicable to entire recovery units (Corn, 1994; Anderson et al., 2001; Tracy et al., 2004). In 1999 the Desert Tortoise Management Oversight Group endorsed the use of line distance sampling (Buckland et al., 2001) for estimating range-wide desert tortoise density.

Distance sampling methods use measurements taken from the center of the transect lines to tortoises to model detection as a function of distance from the walked path; tortoises farther from the travelled path have a lower probability of detection. In order to anchor the curve and estimate the true (not relative) proportion of tortoises detection within a given distance from the center of the transect, all tortoises must be detected on the transect centerline (Anderson et al., 2001; Buckland et al., 2001). There are additional assumptions in distance analysis – that distance is measured to the point where the animal was first detected and that distance is measured accurately – but these are easily satisfied in line distance sampling of desert tortoises. The assumption that detection at the centerline of the transect is perfect, however, can be violated during line distance sampling of tortoises, but the use of two observers minimizes the probability that tortoises are missed on the centerline and provides a correction factor in the form of an estimate of the number of tortoises on the line that were missed (USFWS, 2009).

Distance methods have been applied to estimate abundance of Sonoran Desert Tortoises (*G. morafkai*) since 2000 (Swann et al., 2002; Averill-Murray and Averill-Murray, 2005) and for *G. agassizii* in the Upper Virgin River Recovery Unit in Utah since a pilot study in 1997 (McLuckie

AR060103

et al., 2010). The USFWS used line distance sampling to estimate abundance of tortoises in the remaining five recovery units for *G. agassizii* in Utah, Arizona, Nevada, and California starting in 2001 (USFWS 2006, 2009, 2012a, 2012b, 2012c). This report includes results of training exercises for field crews, describes implementation of monitoring, and presents the analysis of desert tortoise density in 2012.

METHODS

Study areas and transect locations

Long-term monitoring strata (Figure 1) will be used over the life of the project to describe population trends in areas managed to conserve tortoises ("tortoise conservation areas," TCAs). Generally each critical habitat unit (CHU) is treated as one monitoring stratum, although the portion of Mormon Mesa CHU that is associated with Coyote Springs Valley is treated as a separate stratum. Chuckwalla CHU is also treated as dual monitoring strata, with potentially unequal sampling effort in the areas managed by the Department of Defense (Chocolate Mountain Aerial Gunnery Range, CMAGR) and by the Bureau of Land Management (BLM). New recovery units were established under the revised recovery plan (USFWS, 2011), so while making the corresponding changes to our databases we also separated the Piute and Eldorado Valleys into 2 distinct strata; they are in different recovery units. The Joshua Tree stratum does not encompass all suitable habitat for desert tortoises in Joshua Tree National Park (JTNP). The national park designation and current boundaries just post-date the designation of CHUs, so some of the Pinto Mountains and Chuckwalla CHUs (and monitoring strata) are in the current JTNP.

The optimal number of transects in a monitoring stratum was determined by evaluating how these samples would contribute to the precision of the annual density estimate for a given recovery unit (Anderson and Burnham, 1996). Power to detect an increasing population size is a function of 1) the magnitude of the increasing trend, 2) the "background noise" against which the trend operates, and 3) the length of time the trend is followed (even a small annual population increase will result in a noticeably larger population size if the increase continues for many years).

The magnitude of the population trend is a function of recovery activities and the population dynamics of the tortoise – neither of these elements are affected by monitoring design and sample size. The second contributor to the power to detect a trend – the level of background variability in the density estimates – is directly affected by the number, length, and placement of transects in the monitoring strata. Anderson and Burnham (1996) recommended that transect number and length be chosen to target precision reflected in a coefficient of variation (CV) of 10-15% for the estimate of importance (here, density for tortoise conservation areas in each recovery unit). The CV describes the standard deviation (a measure of variability) as a

AR060104

proportion of the mean and is often converted to a percentage. Since recovery criteria target trends within recovery units (USFWS, 2011a), precision in that density estimate was the focus. The target CV is achieved based on the number of tortoises that might be encountered there (some strata currently have higher densities than others), as well as the area of the stratum – its proportional contribution to the recovery unit density estimate (Buckland et al., 2001).

The actual number of transects assigned in each stratum was a function of the optimal numbers described above, as well as on available funding. Once the number of transects in a stratum was determined, these were laid out systematically across strata, with a random origin for the lattice of transects. In strata with more assigned transects, nested lattices with smaller spacing (3 km) were used to ensure sufficient transects. In strata with fewer transects, lattices 9 km spacing were used. Systematic placement provides more even coverage of the entire stratum, something that may not occur when strictly random placement of transects is used. In both cases, transects are located at random with respect to the location of desert tortoises.

Distance sampling transect completion

One adaptation that tortoises have for living in the desert is to restrict surface activity to fairly narrow windows of time during the year. In general, tortoises emerge from deep within shelters (burrows) from mid-March through mid-May and then again (less predictably) in the fall. These periods coincide with flowering of their preferred food plants (in spring) and with annual mating cycles (in fall). The annual range-wide monitoring effort is scheduled to match the spring activity period for tortoises.

During this season, not all tortoises are above ground or visible in burrows. To encounter as many tortoises as possible, monitoring is scheduled for early in the day and to be completed before the hottest time of day. Because tortoises are located visually, monitoring is restricted to daylight hours. Based on past experience, we expect tortoises to become most active after 7am at the beginning of April (it is usually too cool before this time), but to emerge earlier and earlier until their optimal activity period includes sunrise by the beginning of May. In May, we also expect daytime temperatures to limit tortoise above-ground activity as the morning progresses to afternoon.

DRAFT

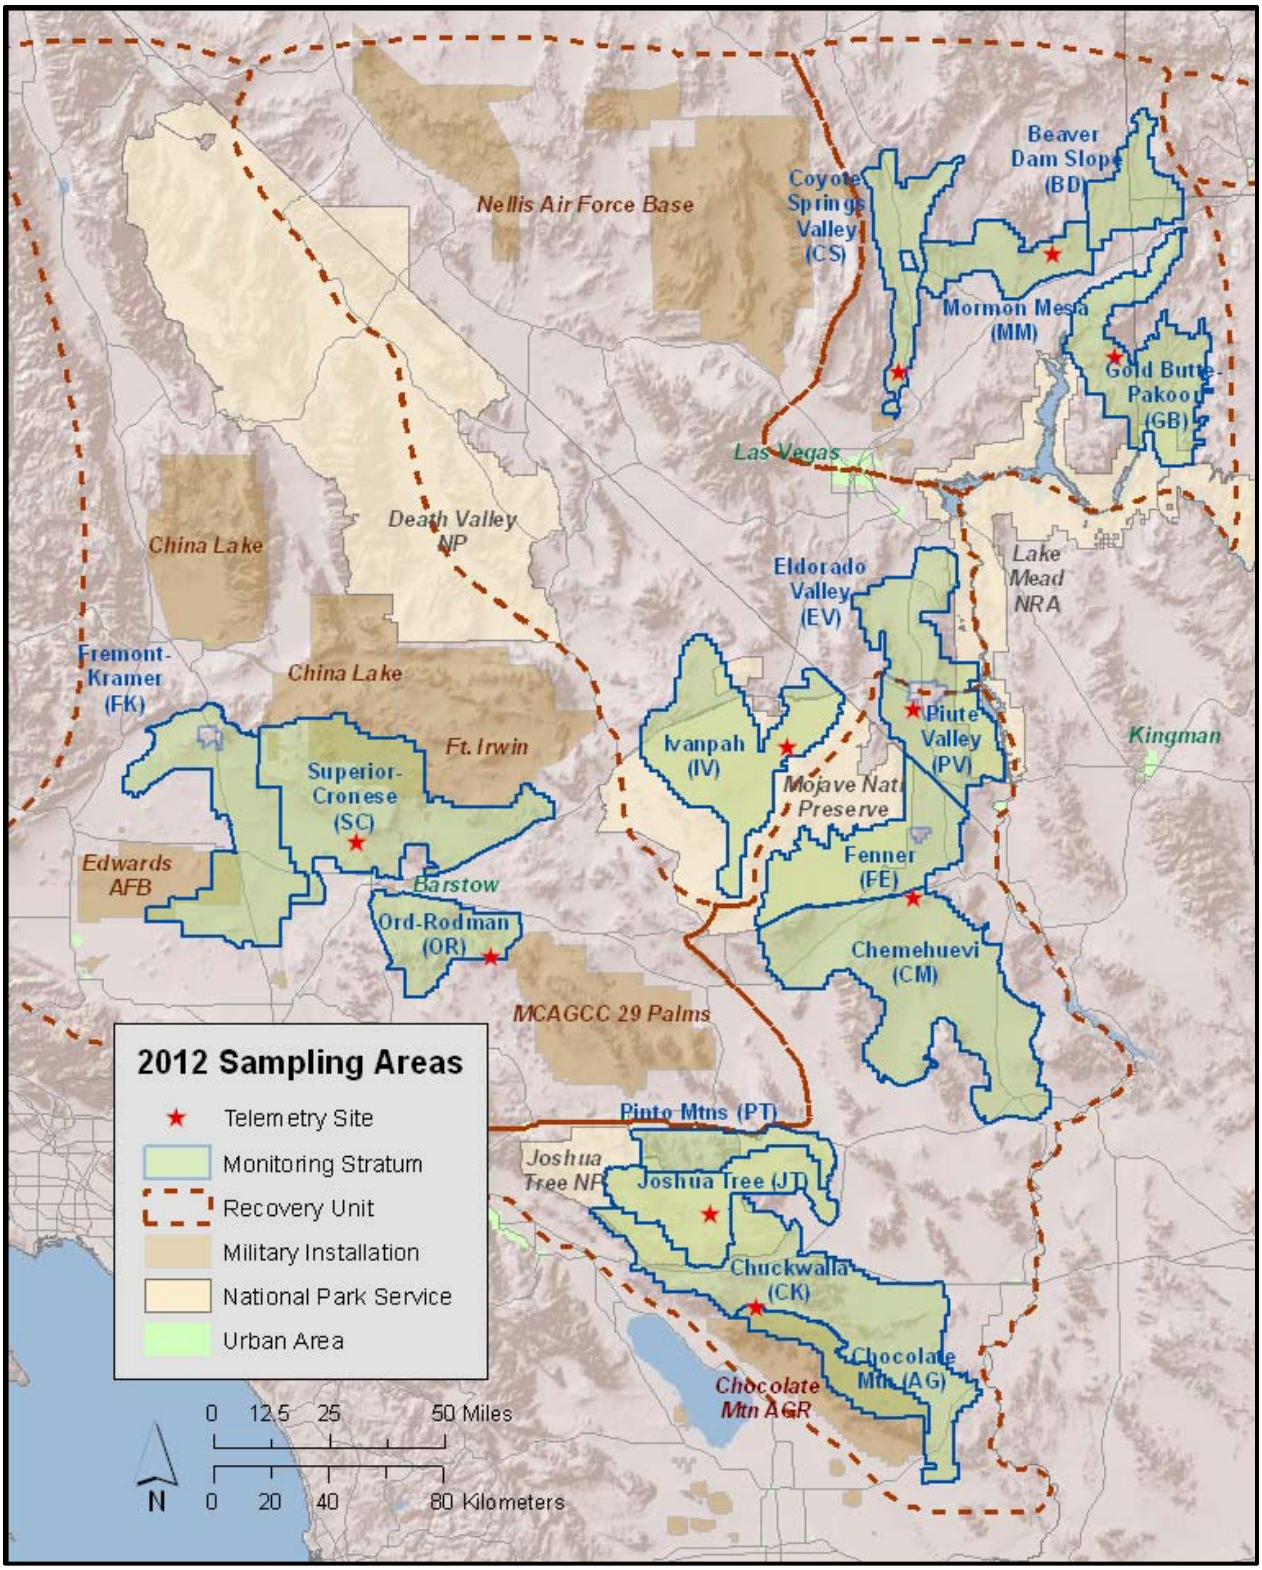

Figure 1. Sampled areas 2012.

Field crews complete transects during this optimal period each day. Start times are decided a week in advance, so crews arrive at transects at similar times on a given morning. However, completion times will be more variable, as a consequence of terrain, air temperature, number of tortoises encountered, etc. Under normal conditions, each team walked one 12 km square transect each day. Teams were comprised of 2 field personnel who switched lead and follow positions at each corner of each transect, so they each spent an equal amount of time in the leader and follower positions. The leader walked on the designated compass bearing while pulling a 25 m length of durable cord; the walked path is also the transect centerline and was indicated by the location of the cord. The length of cord also spaced the two independent observers, guiding the path of the follower; when the cord was placed on the ground after a tortoise or carcass was detected, it facilitated measurement of the local transect bearing. The walked length of each transect was calculated as the straight-line distance between GPS point coordinates that were recorded at 500 m intervals (waypoints) along the transect and/or whenever the transect bearing changed.

Both leader and follower scanned for tortoises independently without leaving the centerline, and the role of the crew member finding each tortoise was recorded in the data. Although the leader saw most of the tortoises, the role of the follower was to see any remaining tortoises near the centerline, so the follower role is crucial to unbiased estimation of tortoise densities.

Distance sampling requires that distance from the transect centerline to tortoises is measured accurately. When a tortoise was observed, crews 1) used a compass to determine the local transect bearing based on the orientation of the 25 m centerline, 2) used a compass to determine the bearing from the point of observation to the tortoise, and 3) used a measuring tape to determine the distance from the observer to the tortoise. These data are sufficient to calculate the perpendicular distance from the observed tortoise to the local transect line. If the tortoise was outside of a burrow, was handled enough to measure midline carapace length (MCL), to determine its sex, assess its body condition (USFWS 2011b), and to apply a small numbered tag to one scute. If a tortoise could not be measured because it was in a burrow, because temperatures precluded handling, or for any other reason, crews attempted to establish by other means whether the animal was larger than 180 mm MCL, the criterion for including animals in density estimates.

Because transects are 3 km on one side, it is not unusual for that path to cross through varied terrain or even be blocked by an obstacle such as an interstate highway. In the first years of this program, smaller transects in inconvenient locations were shifted or replaced, but this compromised the representative nature of the sample. Since 2007, the basic rules for modifying transects involve 1) reflecting or elongating transects to avoid obstacles associated with human infrastructure (large roads, private inholdings, etc.), or 2) shortening transects in rugged terrain. Substrate and access to transects can also make it difficult to complete transects during the

AR060107

optimal period of times, so 3) transects could be shortened to enable completion before 4pm each day.

In 2008 and 2009, the rules for shortening transects were made more restrictive. Crews had the option to complete transects that were 12 km long (in low-relief terrain) or 6 km long (where higher-relief terrain precluded completion of 12 km in a working day). In the latter case, to avoid crews selecting particular terrain, the only way to shorten the transect was to walk it in the southwestern quadrant of the intended 12 km square. If the southwestern quadrant was judged too rugged to be completed safely by transect walkers, the final option was to not complete the transect at all.

In 2010 and 2011, the same option to shorten transects to 6km in rugged terrain were made available to crews in the eastern portion of the range where there was sufficient funding to substratify encounter rates for flat and rugged terrain. In the western part of the range, crews shortened transects by following as much of the planned 12 km route as was possible. This technique was implemented in 2012 for the entire range. If it was anticipated that fewer than 4 km could be walked, the transect should be replaced instead with a transect from the alternate list. I assumed that the proportion of the area that is unwalkable is the same as the proportion of total planned kilometers (12 X number of planned transects) that were unwalkable. As in previous years, unwalked transects were replaced from the list of alternates. More situations were anticipated by additional rules in 2010, as described below.

Transects that crossed stratum boundaries into public lands had previously been walked as planned (squares). Although this added sampling just outside the stratum, it seemed reasonable to assume the land management and tortoise fate would be similar on each side of the invisible boundary. Walking in a square is also less likely to introduce other problems compared to reflecting the transect. Nonetheless, starting in 2010, the protocol used to modify transects that intersected private lands or interstates since 2007 was applied to the portion of any transect that crossed out of monitoring strata, reflecting that portion into the stratum. Whether the segments of those transects outside the boundaries were walked outside the stratum or as a mirror image inside the stratum, the same length of transect was walked at the same distance from the stratum boundary, avoiding undersampling of areas on stratum boundaries (Figure 2). The impetus for this change was the recent large scale development and construction on public lands, often just along the borders of critical habitat, especially for renewable energy facilities and transmission lines.

Specifics of how transect paths were to be modified for rugged terrain (shortened) or for administrative boundaries (reflected) can be found in the *2012 Desert Tortoise Monitoring Handbook* (USFWS 2012d).

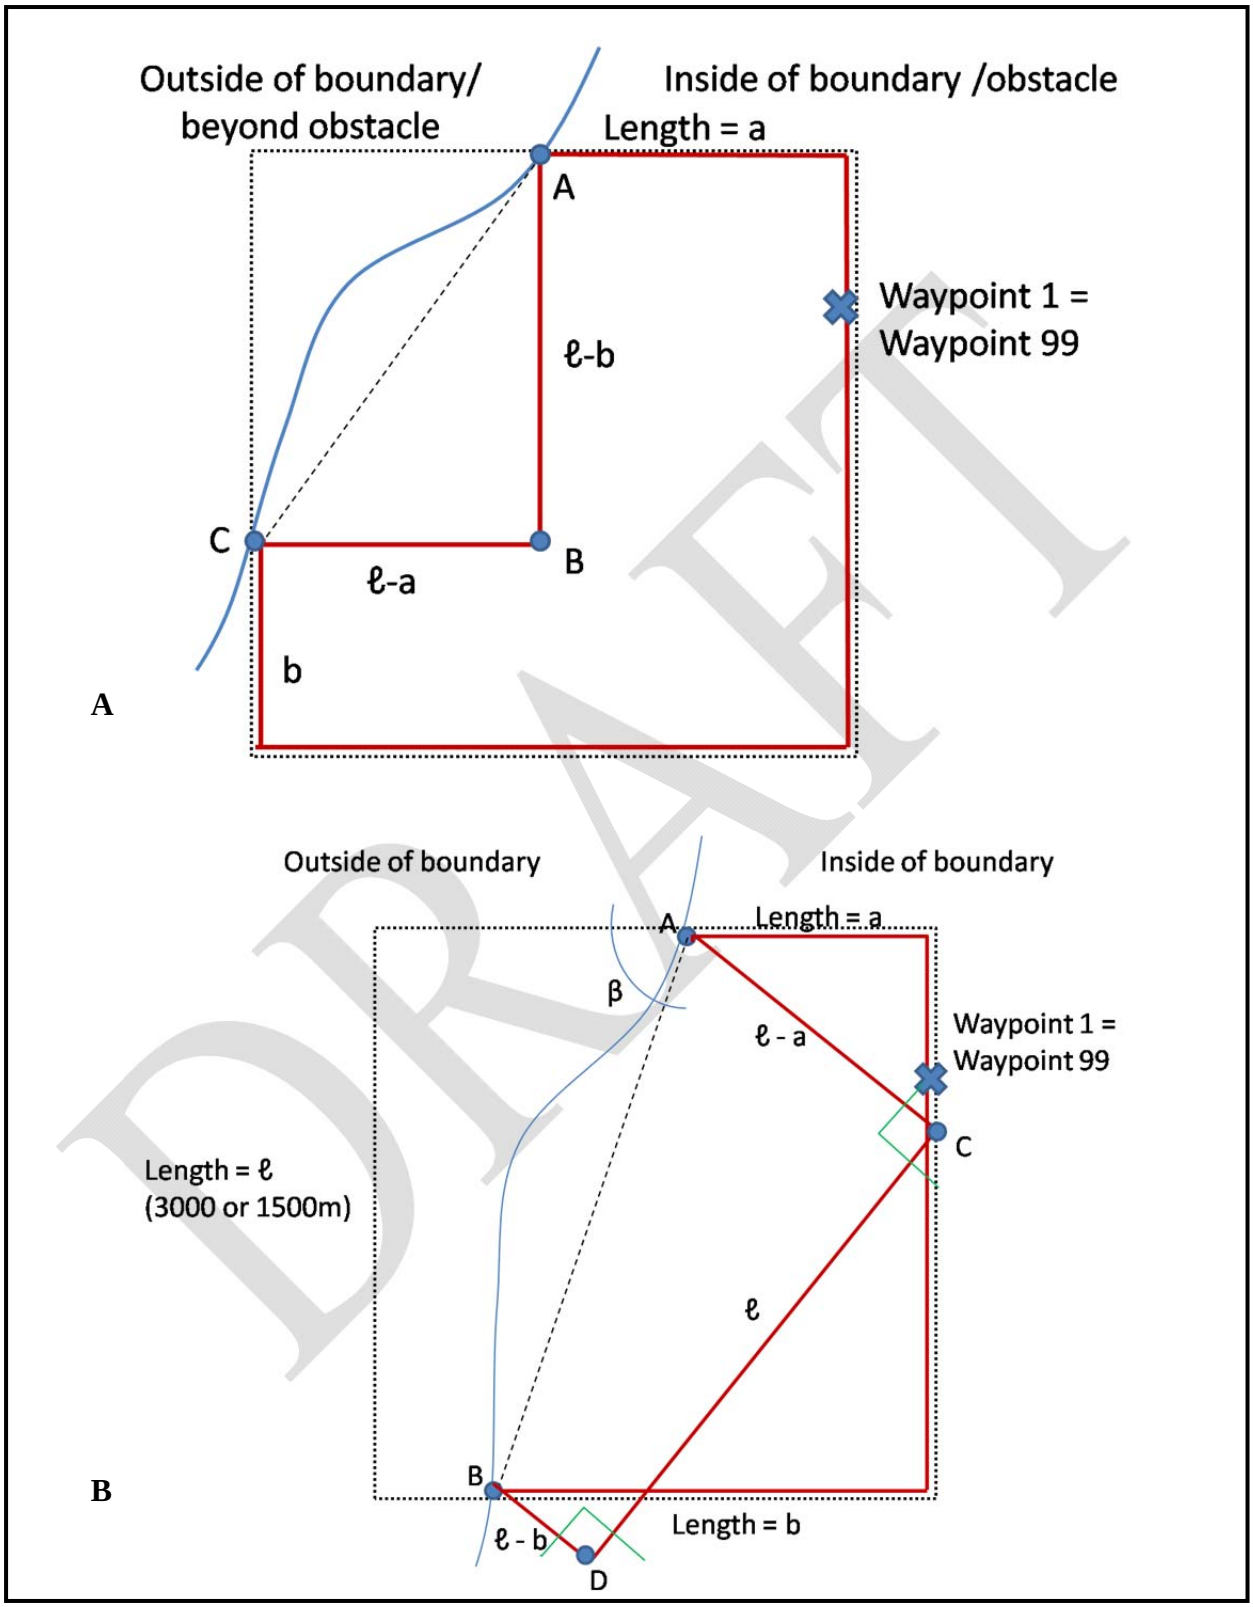

Figure 2. Planned (dotted lines) and reflected transect paths at administrative boundaries, now also applied to stratum edges. A) One-corner reflection. B) Two-corner reflection.

Proportion of tortoises available for detection by line distance sampling, G_0

Although we have general expectations about when tortoises are most active each day, and plan our sampling to match the best season and time of day, the fact remains that basing our density estimates only on the tortoises that are visible will result in density estimates that are consistently underestimated (biased low). Instead, we use telemetry to estimate the proportion of tortoises available for sampling, G_0 ("gee-sub-zero"), which is incorporated in the equation for estimating tortoise density and is used to correct this bias.

Telemetry allows us to locate radio-equipped tortoises that are visible as well as those that are otherwise undetectable in deep burrows or well hidden in dense vegetation. To quantify the proportion that were available for detection ("visible") in 2012, telemetry technicians used a VHF radio receiver and directional antenna to locate 9-19 radio-equipped G_0 tortoises in each of 10 sites throughout the Mojave and Colorado deserts (Fig. 1).

Each time a transmittered tortoise was located, the observer determined whether the tortoise was visible (*yes* or *no*). Through careful coordination, observers at telemetry sites monitored visibility during the same daily time period when field crews were walking transects in the same region of the desert. Observers completed a survey circuit of all focal animals as many times as possible during the allotted time, recording visibility each time. Bootstrapped estimates of G_0 started by selecting one visibility record at random for each tortoise on each day it was located. The average visibility of all tortoise observations at a site on a given day was calculated and used to estimate the mean and variance of G_0 at that site. When there was more than one site in a given area, the G_0 estimate was calculated as the grand mean of all G_0 sites in the group. One thousand bootstrap samples were generated in PASW Statistics (release 18.0.2; SPSS, Inc., 2 April 2010) to estimate G_0 and its standard error.

Use of radio transmitters/receivers to locate tortoises is a technique that is very different from the method used to detect tortoises on line transects. Therefore, in addition to stating whether any part of the tortoise is visible when located, since 2008 behavioral observers and transect walkers have categorized all "visible" tortoises and burrows (when tortoises are found in burrows) as low, medium, or high visibility based on the ability to see part of the tortoise or its burrow from any angle of approach. For the telemetry observers it is a matter of locating a tortoise (visible or not) after they have determined its general location aurally, whereas transect walkers are not searching with certainty of locating a tortoise – they rely only on visual cues. We would therefore not be surprised if the distance sampling method results in detection of a higher proportion of "high" visibility and a lower proportion of "low" visibility tortoises/burrows than when tortoises are located using telemetry. If the odds be being detected differ not only by distance from the line but also a combination of method of detection used (visual or radio receiver) and visibility, we should be able to describe this difference and be able to modify our calculation of visibility following radio-receiver information to more accurately match the visibility to transect walkers.

AR060110

Field observer training

Training for careful data collection and consistency between crews is fundamental part of quality assurance for this project. This training includes instruction as well as required practice time on skills such as tortoise handling, walking practice transects, and developing detection and distance-measuring techniques. The latter skills include practice on a training course with tortoise models (Table 1). The monitoring handbook developed in 2008 was comprehensive, and serves as a training manual and documentation of training that is provided. Chapters are updated each year as needed and printed for training. They are also posted to the Desert Tortoise Recovery Office website (http://www.fws.gov/nevada/desert_tortoise/reports).

In 2012, three teams of field observers participated. Kiva Biological (Kiva) supplied crews for monitoring in the West Mojave and the eastern portion of the Colorado Desert recovery units. The Institute for Wildlife Studies (IWS) monitored in the western portion of the Colorado Desert and in the Eastern Mojave recovery units. Great Basin Institute (GBI) supplied crews for monitoring in the Northeastern Mojave Recovery Unit. Eight of 10 personnel for Kiva had previous experience with this monitoring program, as did 2 of the 11 personnel for IWS, and 12 of the 26 personnel for GBI were returnees. The three teams were trained in 2 overlapping periods, and to enhance consistency in application of field protocols across teams, where possible the same trainers were used in both training sessions and across teams. Also, for small-group training, experienced personnel from each team worked with the trainees from other teams.

Telemetry training

The primary goal of G_0 training is successful implementation of the G_0 protocol by telemetry crews. This includes correct use of telemetry equipment, understanding G_0 data collection fields, observation of as many radio-equipped tortoises as possible during the day, and covering a window of observation that overlaps the day's transect observation period for each sampling area. Although all telemetry crews had some prior telemetry experience, performance on this project differs from others that do not require confirmation of the exact location of the tortoise. Unless the exact location is determined, its visibility cannot be accurately recorded. Beyond instruction and testing on use of the equipment in desert terrain, several days of practice were compulsory to be able to troubleshoot locating the tortoise and confirming the location when it could not be seen, In addition, some instruction for telemetry and transect crews overlapped to help each group better understand the purpose their data serve and how separate data types are related to the final density estimate.

Distance sampling training

Transect walkers were given classroom instruction, field demonstrations, practice transects to complete, and ultimately each team was evaluated based on performance on a field arena outfitted with a high density of polystyrene tortoise models placed in measured locations (Anderson et al., 2001).

AR060111

Polystyrene desert tortoise models were set out on the training course each year using placement instructions (vegetation or open placement, distance along training line, and distance perpendicular from training line). This course was used to determine whether 1) individual teams are able to detect all models on the transect centerline, 2) whether their survey techniques yield useful detection functions, and 3) whether they can accurately report the distance of each model from the transect centerline. For each purpose, many opportunities must be provided, so the course is populated at a very high density of models (410/km^2).

Crews were sent on transects and training lines as paired, independent observers. That is, the follower was 25 m behind the leader, with the opportunity to detect models not found by the leader. If the leader detects 80% of all tortoises that are found, the assumption is that the follower detects 80% of the tortoises that are missed by the leader. If this assumption is true, in this example, the pair together will detect 0.80 + (0.80 X (1 – 0.80)) = 0.96 of all tortoises on the centerline. Because the location of all models was known, data from training lines were also used to 1) assess the dual-observer assumption that all models were equally detectable (detections attributed to the follower occur at the same rate as original detection rate by leader), and 2) to estimate the detection rate using this technique for tortoises elsewhere in the Mojave Desert. These data on models were used to evaluate and correct crew performance before the field season, but were not used in any way to estimate densities of live tortoises once field surveys began.

Data management including quality assurance and quality control

Two sets of data tables are maintained through the field season, organizing data collected on transects and at the G_0 sites. Collection data forms, sheets, applications, and databases are designed to minimize data entry errors and facilitate data verification and validation. Data were collected in both electronic and paper formats by the two survey organizations, then combined and processed in a series of phases to create final database products. Data quality assurance and quality control (data QA/QC, also known as verification and validation) is performed during the data collection, data integration, and data finalization phases. During the second, data integration phase, after combining data from separate groups, some attribute fields are added and all fields are formatted for final processing. The third phase, data finalization, involves consolidation, resolution of data inconsistencies, and generation of final spatial and non-spatial data products used for analysis. After data analysis and reporting are completed, electronic data are actively hosted for download from the internet through http://www.mojavedata.gov/deserttortoise_gov/recovery/data.php. Figure 3 describes the overall data flow.

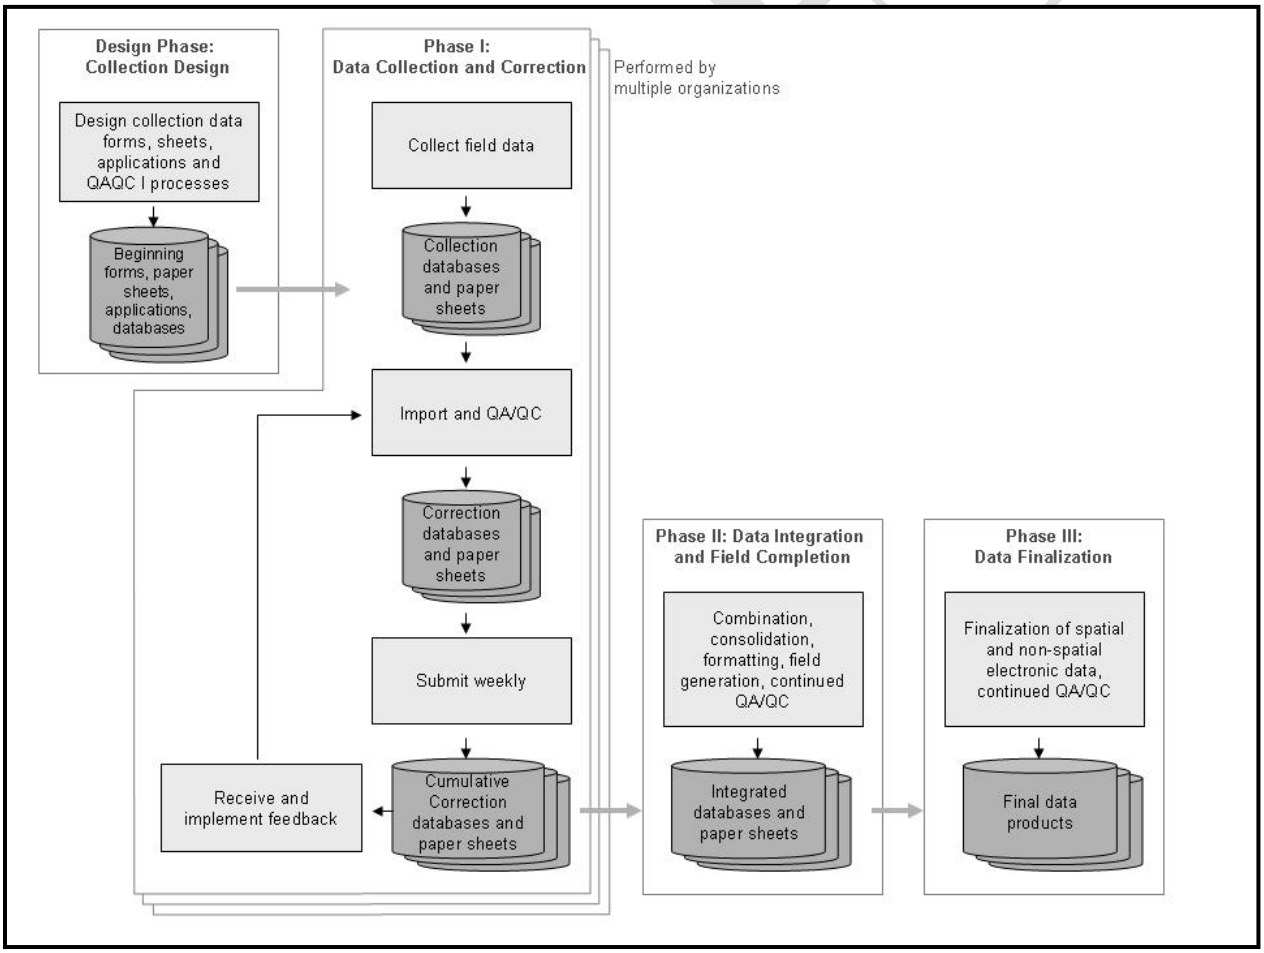

Figure 3. Data flow from collection through final products.

AR060118

Tortoise encounter rate and development of detection functions

The number of tortoises seen in each stratum and their distances from the line are used to estimate the encounter rate (tortoises seen per kilometer walked), the detection rate (proportion of available tortoises that are detected out to a certain distance from the transect centerline), and their respective variances. Detection function estimation is "pooling robust" under most conditions (Buckland et al., 2001). This property holds as long as factors that cause variability in the curve shape are represented proportionately (Marques et al., 2007). Factors that can affect curve shape include vegetation that differentially obscures vision with distance, and different detection protocols used by individual crews (pairs). Field teams (IWS, GBI, Kiva) typically walk different number of transects. For this reason, after the field season I expected to develop at least one curve for each field team, which also corresponds to different regions of the desert. The encounter rate is less sensitive to small sample sizes, so it was estimated for each stratum separately.

I used Program DISTANCE, Version 6, Release 2 (Thomas et al., 2010) to fit appropriate detection functions, to estimate the encounter rate of tortoises in each stratum, and to calculate the associated variances. One record was created for each transect, with additional records for each additional tortoise on that transect. Analysis was applied to all live tortoises larger than 180 mm MCL. Transects were packaged into monitoring strata ("regions" in Program DISTANCE).

I truncated observations to improve model fit as judged by the simplicity (reasonableness) of the resulting detection function estimate (Buckland et al., 2001:15-16)**.** Using truncated data, I used the Akaike Information Criterion (AIC) to compare detection-function models (uniform, half normal, and hazard-rate) and key function/series expansions (none, cosine, simple polynomial, hermite polynomial) recommended in Buckland et al. (2001).

Proportion of available tortoises detected on the transect centerline, *g(0)*

Transects were conducted by 2-person crews using the method adopted beginning in 2004 (USFWS, 2006). Transects were walked in a continuous fashion, with the lead crew member walking a straight line on a specified compass bearing, trailing about 25 m of line, and the second crew member following at the end of the line. This technique involves little lateral movement off the transect centerline, where attention is focused. Use of two observers allows estimation of the proportion of tortoises detected on the line; this provides a test of the assumption is that all tortoises on the transect centerline are recorded ($g(0) = 1$). The capture probability (p) for tortoises within increasing distances from the transect centerline was estimated as for a 2-pass removal estimator (White et al., 1982): p = (lead–follow)/lead, where lead = the number of tortoises first seen by the observer in the leading position and follow = the number of tortoises seen by the observer in the follower position. The corresponding proportion detected on the line by two observers was estimated by $g = 1 - q^2$, where $q = 1 - p$. Figure 4 graphs the relationship between the single-observer detection rate (p) and the corresponding

AR060119

dual-observer detection rate (*g(0); "gee at zero"*). The actual proportion detected can be estimated, but to avoid the necessity of compensating for imperfect detection, during training field crews (pairs) are expected to detect 96% of all models within 1 m of the transect centerline. This corresponds to the leader being responsible for at least 80% of the team's detections near on the centerline in order to meet this standard (Fig. 4) and is the basis for one of the training metrics (see Table 3).

Few or no tortoises are located exactly on the line, and even examining a small interval (such as 1 m on each side of the transect line) results in few observations to precisely estimate *g(0).* Instead, my test of the assumption involves examination of the lead and follow proportions starting with counts of tortoises in larger intervals from the line, moving to smaller intervals centered on the transect centerline. As the intervals get smaller the sample sizes also get smaller, but the estimates are more relevant to the area right at the transect centerline. The expectation is that the estimates should converge on *g(0)* = 1.0.

If the test does not indicate that all tortoises were seen on the transect centerline, the variance of *p* can be estimated as the binomial variance = $q(1 + q)/np$ (White et al., 1982), where *n* = the estimated number of tortoises within 1 m of the transect centerline, and the variance of *g(0)* is estimated as twice the variance of *p*.

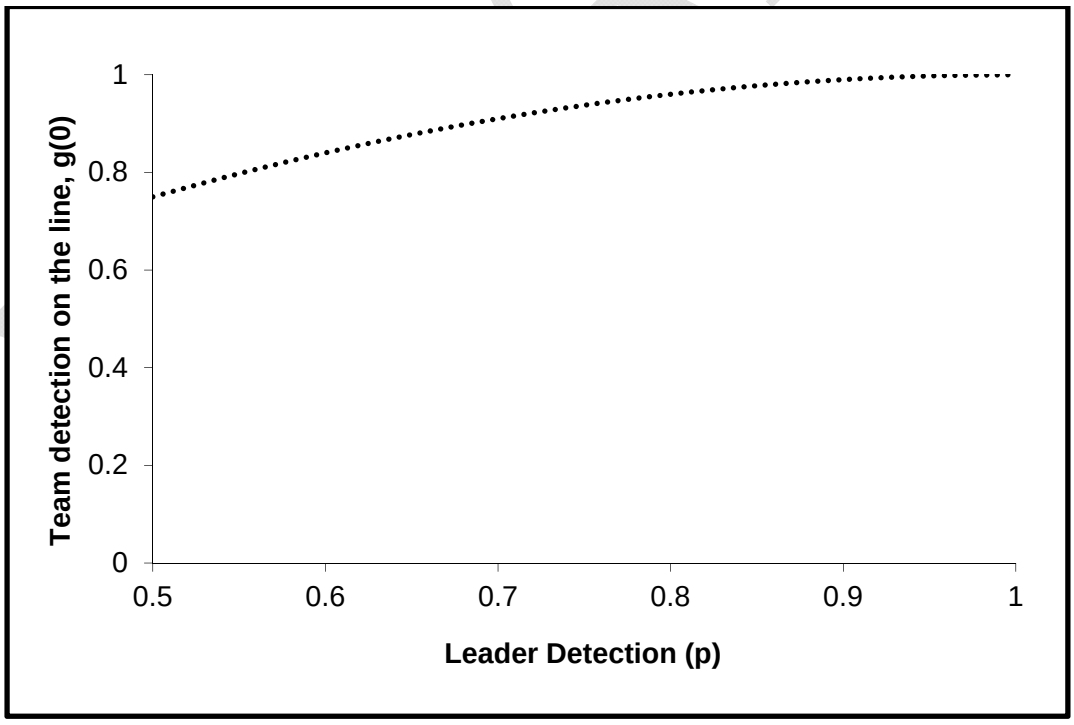

Figure 4. Relationship between single-observer detections (by the leader, *p*) and dual-observer (team) detections, *g(0).*

AR060120

Estimates of tortoise density

Each year, the density of tortoises is estimated at the level of the recovery unit. The calculation of these densities starts with estimates of the density of tortoises in each stratum from Program DISTANCE, as well as their variance estimates:

$$D = \frac{n}{2wLP_aG_0g(0)},$$

where L is the total length of kilometers walked in each stratum and w is the distance to which observations are truncated, so $2wL$ is the area searched in each stratum. This is a known quantity (not estimated). P_a is the proportion of desert tortoises detected within w meters of the transect centerline and was estimated using detection curves in Program DISTANCE. The encounter rate (n/L) and its variance were estimated in Program DISTANCE for each stratum. Calculation of D requires estimation of n/L, P_a, G_0, and $g(0)$. This means that the variance of D depends on the variance of these quantities as well.

For desert tortoise densities, the encounter rate (n/L) is estimated independently for each stratum ("unpooled"), whereas proportion of available tortoises and proportion of available tortoises detected on the transect centerline are estimated jointly for all strata ($g(0)$) or for all strata in the recovery unit (G_0). The detection function, which comes into the above equation as P_a, may be estimated jointly or separately for each team, depending on the number and quality of observations. In 2012, separate detection curves were created for each team (GBI, Kiva, and IWS, pooled across all strata surveyed by that team. A schematic of the process leading to density estimates is given in Figure 5. Contributing estimates in the four left-hand columns are listed with the subsets of the data on which they are based. These estimates combined from left to right to generate stratum and recovery unit density estimates.

Whereas the number of tortoises in the set of strata representing a recovery unit can simply be added together, the variance must be arrived at by accounting for whether this involves pooled or unpooled estimates. As described above, three of the four estimates that contribute to calculating density in a stratum were based on data "pooled" from other strata as well, so when encounter rate and detection probability data from these strata are combined, the correlated nature of the detection probability variances has to be accounted for, for instance. Specifically, the method described in Buckland et al. (2001:89) was used to combine density variances correctly and arrive at the variance (and confidence intervals and CV) for the recovery unit. Pooled and unpooled variance estimates cannot currently be combined as needed in Program DISTANCE, so final construction of density mean and variance estimates from the above components was completed without specialized software.

Estimating the area of each stratum sampled and the number of tortoises in that area

Before the 2008 field season, based on experience in 2007 and visual examination of DEM overlays, all assigned transects were classified as possible for completion as 12k, shortened, or as unwalkable (USFWS 2012a). These classifications before the field season are advisory only, because exact ground conditions, weather, and crew condition all affect the ability to complete a transect. If a non-standard transect (not 12 km square) is walked, crews indicate the obstacles they encountered that forced the change in protocol. In addition to the above named factors, substrate that is very loose on a steep slope or that includes large boulders can make progress so slow or treacherous that crews modify the transect.

Each year, some transects are repeated, providing new information on ground conditions, and new transects are attempted. At the end of each field season, transects that were completed differently from expected are evaluated. At that point, a decision is made whether to reclassify the transect. The classification is used to advise future transect completion, but also to estimate the proportion of each monitoring stratum that is actually represented by the walked transects. Proportions used in this report reflect experience with this set of transects through November

AR060122

2012, as well as untested transects that were classified using topographic overlays as part of planning for 2013.

Crews completed all transects using the 12 km square path, completing as much of that path as possible. The calculation of unwalkable area in these strata based on the proportion of unwalkable kilometers, not unwalkable transects. Transects completed as 12 km represent the 100% completion option. The total area of the stratum that is walkable is estimated as:

$$Proportion\ walkable = \frac{transect\ kilometers\ walked}{12\ X\ transects\ completed}.$$

If a given stratum covers 5000 km^2, but only 90% was walkable and represented by our sampling design, then the density estimate applies to 4500 km^2, and can be used to generate an estimate for the number of tortoises in those 4500 km^2. Using these area estimates adds another source of imprecision, so abundance estimates are slightly less precise than the density estimates they derive from. The additional error of this estimate is calculated as the error for a binomial proportion.

Modification of previous procedures

Because tortoises are predictably but not reliably above-ground for parts of the year, there has been continuing interest in use of surveys for sign to estimate number of live animals. The uses and limitations of this approach have been discussed at length, with the performance of live tortoise surveys being preferred. However, on smaller areas of land, few tortoises are expected to be found, so estimates based on live tortoise estimates will be imprecise. Krysik (2002) and Duda et al. (2002) explored the correlation between tortoises and sign using 2 approaches. Although the correlation between sign and live animals was not stable, the interest of land managers in developing better estimates of tortoise numbers in areas smaller than an entire management entity (such as a national park) continue. In 2012, transect walkers counted all burrows that they examined, entering these tallies at the next waypoint. We continued estimating tortoise density using our usual approach, but also provide counts and locations of tortoise burrows so that interested parties can focus on particular areas, interpolating from the critical habitat unit to the smaller parcel based on the relative number of burrows at each scale. This comparison is expected to mirror the relative number of tortoises at each scale, with caveats. Because distance sampling surveyors may not have experience identifying all types and conditions of tortoise shelter sites, tallies were made of any soil or rock openings that was examined for live tortoises and was at least 2 tortoise-lengths deep.

Debriefing to describe strengths and weaknesses of project preparation and execution

At the end of each field season, a debriefing meeting was held to review tasks and responsibilities, strengths and weaknesses of the program, and to plan for the next field season. Because the field teams had disbanded by then, field crew members were surveyed prior to the

AR060123

end of the field season to nonetheless gather their direct input as we identified training and logistical issues to target for improvement before the next field season. Although issues and/or tasks may be ascribed to individual entities, this meeting is most beneficial in identifying where centralized and/or coordinated response is required to improve the quality of the program.

RESULTS

Field observer training

The smaller Kiva and IWS groups trained alongside one another and mostly separate from GBI, although experienced crews worked between all three teams. Training started on 7 March and continued through 27 March (Table 1). Final tests of field detection abilities occurred toward the end of this period.

Proportion of tortoises detected at distances from the transect centerline

Table 2 reports the proportion of models that were available and were detected by each team at 1-, 2-, and 5-m from the transect centerline. Teams were tested after a trial run on the detection lines or after returning crews walked practice transects to refresh the search pattern (3 of 4 Kiva crews). Detection on the centerline should be 100%, and many crews achieved this. Teams 21 and 43 had perfect detection within a meter of the line during their practice trial, so their performance is not a concern.

Table 3 reports further statistics for each team after collecting data on 16 km on the evaluation lines. Measurement accuracy reported in Table 3 gives the average absolute difference between the expected and measured perpendicular distances from the model to the walked line. All measurements for all models during the 2-day trial are used for this estimate, and capture inaccuracies from 1) using a compass and measuring tape to record distances to the models, plus 2) inaccurately following the trajectory of the transect. The latter source of error does not occur on monitoring transects, because the walked transect is the true transect. On training lines, measurement error increases if crew paths diverge from the measured line that was used to place the models. The "Available Models Detected by Leader" column reports the proportion of all models that were found first by the leader. During training, this number is easily calculated and is used to identify crews in which one of the observers is not finding at least 80% of all detected. With an 80% detection rate for the leader, a 96% detection rate is expected for the team.

Although some individual metrics were below-par (gray cells in Tables 2 and 3), all teams performed well overall and no further changes were made. During training, detection curves were fit to each crew's set of tortoise model observations. In no case was the best-fitting model a negative exponential one without a "shoulder" describing detections near the centerline. Detection curves reflecting such a model would have led to additional practice. The best-fitting of the 3 remaining basic types of models were then fit to the data to generate density estimates in Table 3. In Figure 6 to Figure 8, all of the crew detection curves for each field team are overlaid.

AR060124

Crews were not evaluated on their ability to match teammates; such overlays were used to focus field personnel on an additional level of conformity they could work toward. Distance sampling and development of a single detection curve from many observers is robust to the effects of pooling across observations from crews with variable search patterns, when observers contribute proportionally to the overall pattern (Marques et al., 2007).

Table 2. Proportion of tortoise models detected by teams within 1-, 2-, or 5-m of the transect centerline. Values that scored below the target of 0.90 at 1- and 2-m are highlighted.

Team Number	1m	2m	5m
1	1.00	0.96	0.93
2	0.94	0.96	0.87

Kiva	0.99	0.96	0.89
IWS	0.93	0.92	0.90
Overall	0.95	0.93	0.89

The Kiva teams had very similar detection patterns by the time the field season began (Fig. 8). Within the GBI crews, teams 44, 48, and 50 had the most anomalous curves (broadest shoulders) in Figure 6. The usual concern when crews are successful searching farther from the line is that they will focus less close to the line; this was not the case for any of these 3 teams. They were coached on tightening their search pattern to better match other teams, but the patterns were not of concern. The extra detections by some IWS team 23 past 10m (the single curve with an extra pair of inflections), are of most concern when this indicates that one of the searchers is not detecting tortoises at the line. However, Team 23 was otherwise judged to have fairly healthy

AR060125

diagnostics. The testing arena differs from the normal field setting in ways that make it easier to evaluate trainees (higher encounter rate, for example), but also make it more difficult to use as an absolute standard for search patterns.

Table 3. Diagnostics for individual teams after training

Team	Available models detected		Measured v. exact model distance (m)	Estimated abundance	95% confidence interval	
	Within 2m of centerline by leader	Within 2m of centerline by team			Lower limit	Upper limit

Quality assurance and quality control

There were 17,654 transect records and 8216 G_0 records associated with the monitoring effort in 2012. After data specialists with the field teams had finished verifying and validating the information in these 2 databases, there were 461 cases where the data were inconsistent with constraints and expectations. (Note that many more issues are addressed each year by data specialists for field crews before the field data are submitted.) Relatively few (378) were errors created by the field crews (sometimes faulty equipment, other times data entry error), of which all were corrected by later phases of QA/QC with recourse to paper datasheets or were identified as correct but unusual data entries (not errors). Another 140 errors were "processing" errors that were identified and corrected before the final database products were created. Processing steps are associated with correcting other errors (perhaps the correct entry is mis-entered), with adding new fields, or any other manipulation that occurs after the data have been collected. When files of scanned datasheets are missing pages, this is a processing error. Other entries violate QA/QC rules but are extreme or explicable entries; there were 301 of these exceptions which require time to research and are one of the costs of QA/QC. Nonetheless, this year of data had relatively few errors, comparable to the previous year of improved QA/QC, and reflecting the improved processes to limit data entry and processing errors.

AR060128

Transect completion

Table 4 reports the number of assigned and completed transects in each stratum. For the second year in a row, no transects were inadvertently completed twice by different crews. Kiva was assigned 160 transects and walked an additional transect. They consistently replaced any assigned but unwalkable transects with alternates in the same strata. All assigned transects were completed or replaced by IWS, although one unwalkable transect in the Eldorado Valley was replaced by an alternate in neighboring Piute Valley. The Great Basin Institute completed 380 transects, replacing any assigned but unwalkable transects with alternates in the same strata. Great Basin Institute used base-camping in route-less areas to provision crews with supplies, including water, to enable crews to complete 17 transects without returning over large or difficult distances to their vehicles.

Table 4 indicates the number of assigned transects that could be completed as standard square 12km transects or by reflecting around property boundaries and infrastructure (column 4). These transects represent flatter topography. An additional number (column 5) were shortened and represent more rugged terrain. Finally, some transects were considered unwalkable (column 6). Figures 9 through 12 show locations of transects and observations of live tortoises.

Table 4. Number and type of transects in each stratum.

Stratum	Assigned transects	Assigned and alternate transects completed*	Assigned, completed 12k	Assigned, completed shortened	Assigned, judged unwalkable

Burrow encounter rate
We reported tallies of examined burrows at each waypoint, representing a path 500 m long. Crews examined 12,817 burrows, inspecting as many as 30 in a 500 m path between waypoints.

Tortoise encounter rates and detection functions
In 2012, all pairs worked together from the beginning to the end of the season. Each Kiva crew walked on average 41 transects and overall they detected 77 tortoises over 180 mm MCL; GBI crews walked a median of 37 transects and detected 162 tortoises; and IWS crews had considerably lower effort, with a median of 22 transects (days of work). However, each IWS observer subsequently walked 1-person distance transects in a separate study at the Large Scale Translocation Site near Jean, Nevada; altogether IWS personnel completed 31 days of work and the team observed 30 tortoises larger than 180 mm MCL, so the LSTS encounters were used to model the overall IWS detection probability illustrated in Fig. 14. Even when crews have similar levels of effort, if there are sufficient observations to generate separate detection curves for each team, that is preferred to also account for differences in vegetation and other regional differences that may alter detection probabilities.

Figures 13 to 15 are histograms of the observed number of tortoises seen at increasing distance from the transect centerline. There is one histogram for each team (Kiva, IWS, and GBI). These observations were used to model detection curves, overlaid in the same figures. Based on detection function behavior, it is typical to discard a few observations in the tails of the histograms in order to build a more robust model (Buckland et al. 2001). Each figure indicates the customized truncation distance that was applied. Any observations that are not used to estimate detection functions will also not be used to estimate the encounter rate (tortoises detected per kilometer walked). In distance sampling applications for many other species, encounter rate can be estimated with relatively high precision, but tortoise encounter rates are low enough that this becomes a factor in considering how to truncate observations to develop detection functions. Truncation was conservative to maximize the number of observations per stratum.

Kiva detected only 77 tortoises from which a detection curve could be built. All truncation distances considered resulted in approximately the same overall density estimate, so it was preferable to use as many observations as possible to keep precision as high as possible. Use of only observations within 14 m allowed a model with no extra inflections and with all but 5% of the observations. At this distance, the hazard-rate model with no adjustments performed best (Fig. 15). The best-fitting negative exponential model was 3rd best overall.

For GBI, truncation at 21 m required discarding just under 7% of the available observations but provided a fairly simple model fit including g(w) = 10%. The 21 m truncation distance was used

AR060134

(Fig. 13), for which the hazard rate model with 2 parameter estimates but no adjustments fit the data best, and indicate a shoulder of about 2 m – just about 10% of the width.

For IWS, the 5% truncation would be at about 14 m. The model for data truncated at 15 m is a better fit, however, and the hazard rate model with no adjustments performed better than half-normal or uniform models. The shoulder is very narrow, and in fact the best negative exponential model had an AIC slightly less than the selected hazard rate model.

The area below the curves in Figs. 13-15 is the proportion of tortoises that were detected, P_a, estimated as far as the truncation distance (the farthest distance on the x-axis in each figure). Based on these curves, GBI detected 37.9% of the visible tortoises within 21 m of the centerline (CV=0.121). The corresponding estimate of P_a for strata surveyed by IWS was 43.2% (CV=0.263) within 15 m, and for Kiva was 39.7% (CV=0.145) within 14 m.

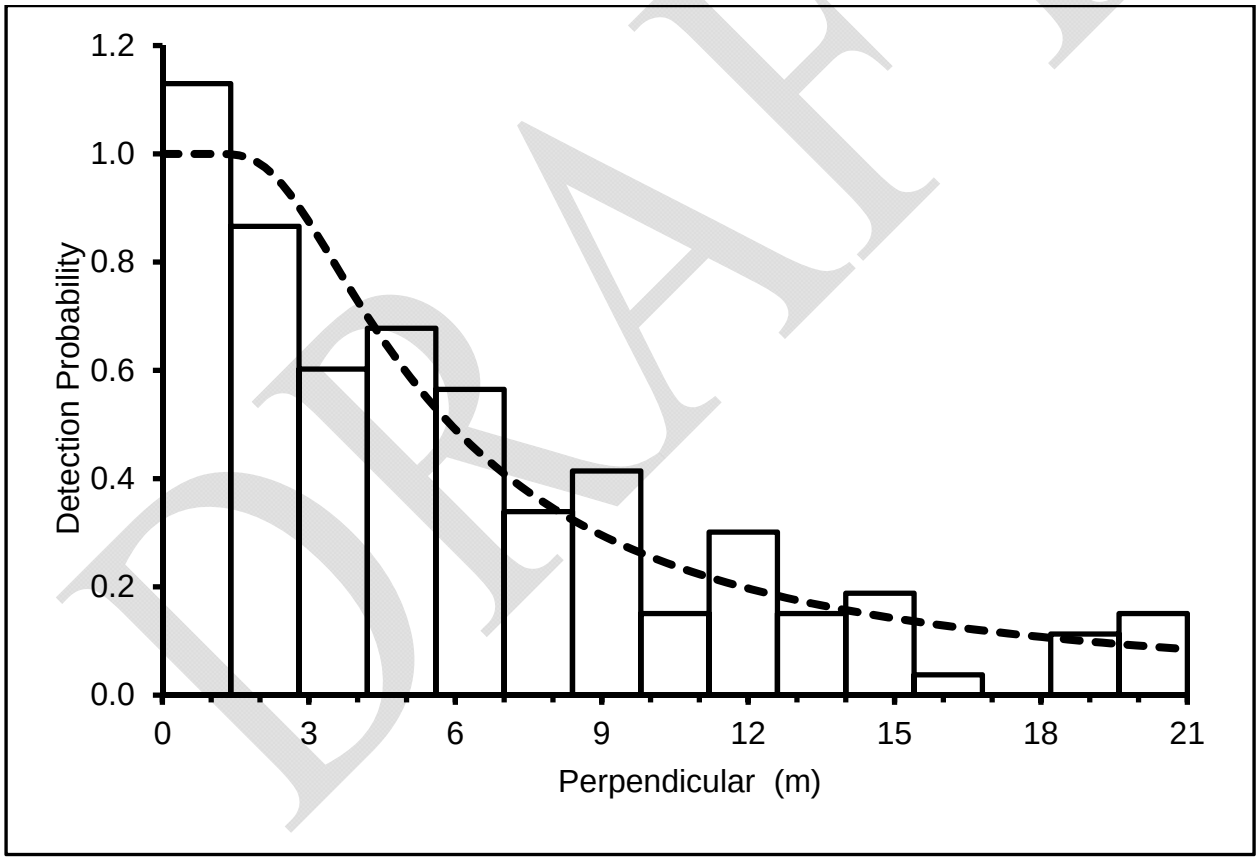

Figure 13. Observed detections (histogram) and the resulting detection function (smooth curve) for live tortoises with MCL ≥ 180mm found by GBI. This curve uses only the 151 observations found within 21 m of the line.

DRAFT

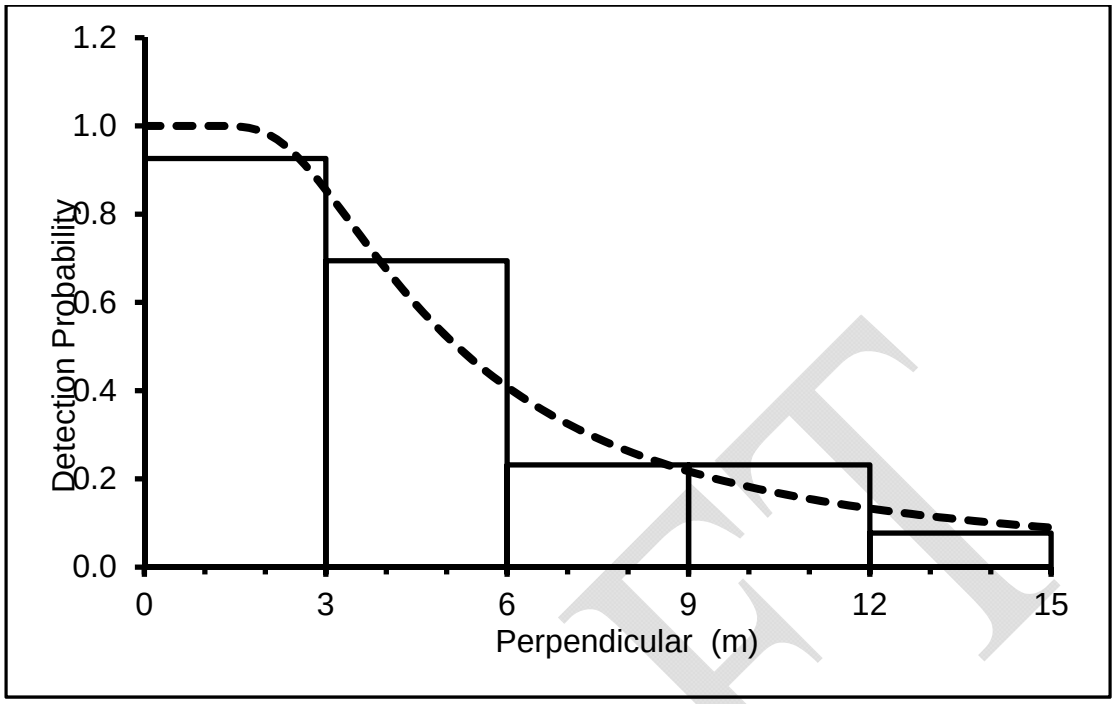

Figure 14. Observed detections (histogram) and the resulting detection function (smooth curve) for live tortoises with MCL ≥ 180 mm found by IWS. This curve uses only the 28 observations found within 15 m of the line.

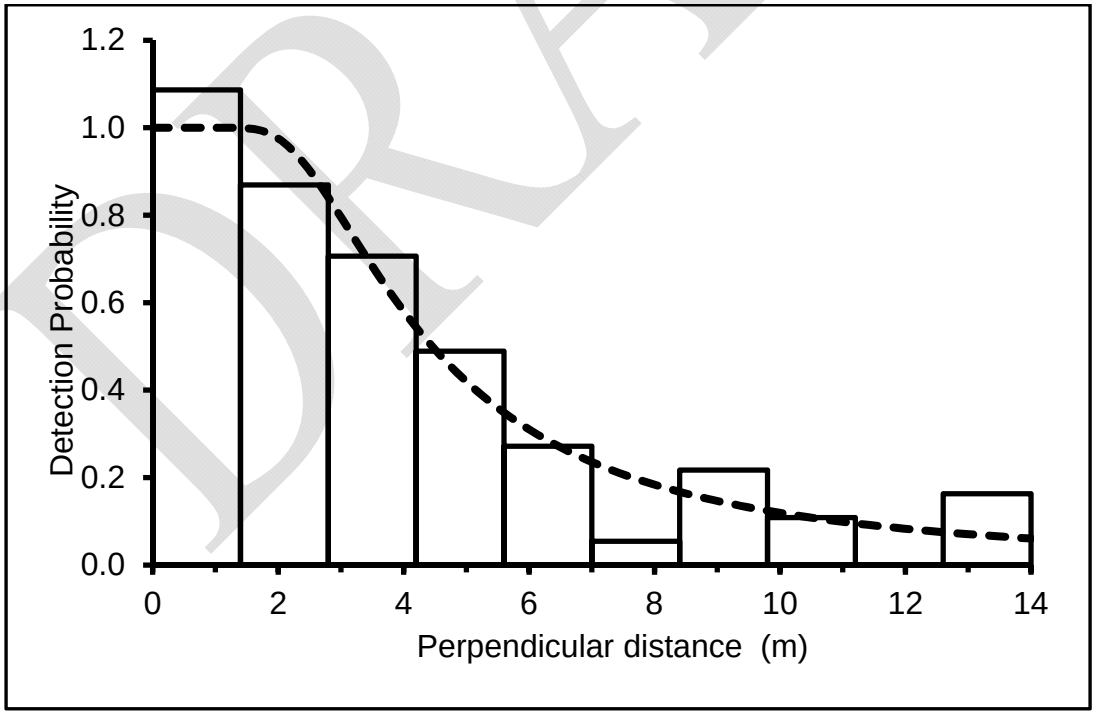

Figure 15. Observed detections (histogram) and the resulting detection function (smooth curve) for live tortoises with MCL ≥ 180mm found by Kiva. This curve uses only the 73 observations found within 14 m of the line.

DRAFT

Proportion of tortoises available for detection by line distance sampling, G_0

In general, telemetry sites and associated transects were completed sequentially, from south to north. This pattern corresponds to the expected timing of tortoise activity; peaking first in the south, later in the north. In 2012, to accommodate access dates on Chocolate Mountain, this stratum was completed before and during training. The remaining strata in the eastern part of the Colorado Desert were started 12 days after this, but visibility from the Chuckwalla and Joshua Tree telemetry sites were high during the entire period, so a single G_0 estimate was used for all of these strata and for the entire 4 week period. Tortoise activity in the eastern part of the range was very delayed compared to typical patterns, and this is reflected in unusually low G_0 estimates for Gold Butte, Halfway Wash, Chemehuevi, Piute-Mid, and Ivanpah, despite the fact that these strata were monitored in April and May. Dates, total days monitored, and G_0 estimates are given in Table 5.

Strata in the western part of the range were apparently sampled during a very active period, reflected in high G_0 estimates. In the eastern part of the range, G_0 remained relatively lower, only increasing slightly in Coyote Springs Valley which was monitored later in the field season.

Table 5. Availability of tortoises (G_0) during the period in 2012 when transects were walked in each group of neighboring strata.

G_0 sites	Strata	Dates	Days	G_0 (Std Error)
Gold-Butte	Gold Butte	27 Mar – 6 Apr	11	0.52 (0.119)
Halfway Wash	Beaver Dam Slope, Mormon Mesa	23 Apr – 21 May	29	0.54 (0.116)
Coyote Springs Valley	Coyote Springs	9 Apr – 22 Apr	14	0.98 (0.049)
Piute/ Ivanpah/ Chemehuevi	Chemehuevi, Eldorado, Fenner, Ivanpah, Piute	28 Mar – 3 May	37	0.52 (0.163)
Joshua Tree/ Chuckwalla	Chocolate Mtn, Chuckwalla, Joshua Tree, Pinto Mtns	13 Mar – 9Apr	28	0.86 (0.107)
Ord-Rodman/ Superior Cronese	Fremont-Kramer, Ord-Rodman, Superior Cronese	10 Apr – 29 Apr	20	0.87 (0.138)

Proportion of available tortoises detected on the transect centerline, *g(0)*

Because they are cryptic, even tortoises that are visible (not covered by dense vegetation or out of sight in a burrow) may not be detected. For 25 detections of tortoises within 1 m of the transect centerline, 21 were found by the observer in the lead position and 4 by the follower, so that the probability of detection by single observer, $p = 0.810$, and the proportion detected using the dual observer method, *g(0 to 1 m)* = 0.964 (SE = 0.11). Figure 16 shows that *g(0)* was converging on 1.0, indicating the assumption of perfect detection on the centerline was met; consequently, no adjustment was made to the final density estimate. The curves since dual

AR060137

observers were first used in 2004 have all supported the premise that complete detection on the transect line was achieved for years in which the dual-observer method was used (USFWS 2009, 2012a, 2012b).

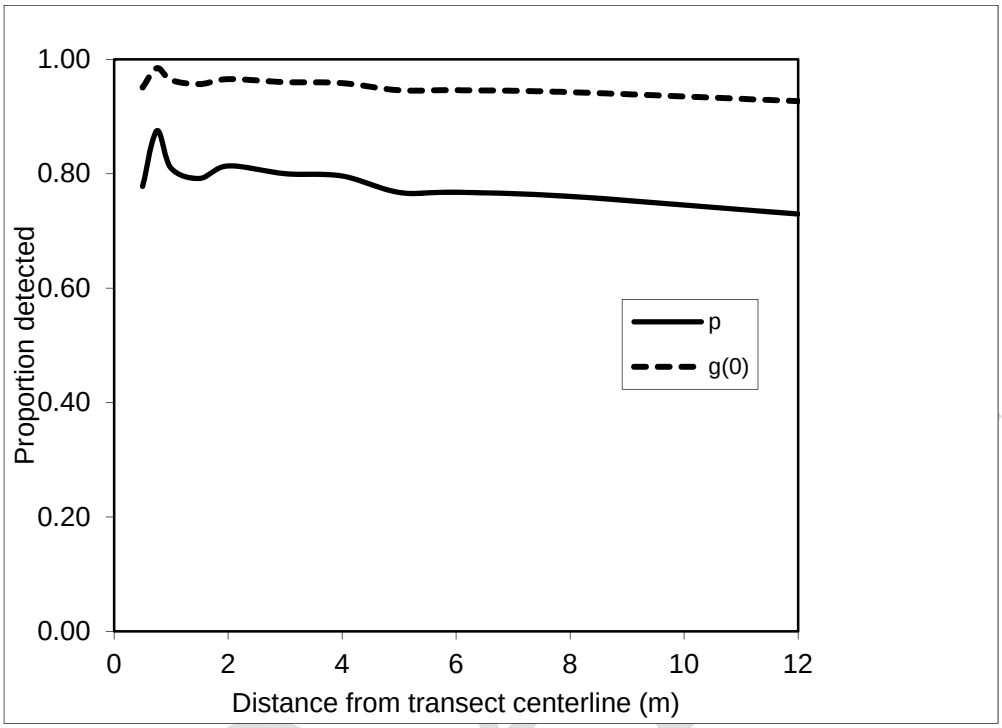

Figure 16. Detection pattern for the leader (*p*) and by the team (*g(0)*) based on all observations out to a given distance (*x*) from the centerline in 2012. Note convergence of *g(0)* on 1.0 as *x* goes to 0.

Estimates of tortoise density

Density estimates were generated separately for each monitoring stratum (Table 6), then weighted by stratum area to arrive at average density in the monitored area of each recovery unit (Table 7). Although encounter rates were estimated separately for each stratum, and have independent variances, the detection function and G_0 were estimated jointly (pooling data from multiple strata), so these variances are not independent (Fig. 5 illustrates how estimates were pooled for 2012).

When the annual estimates are imprecise, it should not be expected that there will be a close match from one year to the next. Over a period of many years, however, we expect any underlying trend in the number of tortoises to be obvious through this "background noise." Some density estimates in 2012 were based on so few observations that the estimates and very high CVs are beyond the expected 20-40% CV. This arose from last-minute funding withdrawals that manifested as sequestration rather than strategic alteration of the sampling design.

AR060138

DRAFT

Table 7. Estimated density of desert tortoises in monitored areas of each recovery unit in the Mojave and Colorado deserts in 2012.

Recovery Unit	Sampled area (km^2)	Kilometers walked	Tortoises detected	Density ($/km^2$)	Lower limit 95% CI (Density)	Upper limit 95% CI (Density)	%CV (Density)
Colorado Desert	13530	1403	44	2.4	1.45	3.95	26.0
Eastern Mojave	3720	639	8	2.2	0.75	6.67	60.5
Northeastern Mojave	4889	4184	164	3.4	2.29	5.00	20.1
Western Mojave	6873	876	33	3.6	2.05	6.21	28.8

Area of each stratum sampled and the number of tortoises in that area

Evaluating transect classification

In 2012, 149 of the 627 walked and 88 unwalked transects were not completed or addressed as predicted. Table 8 summarizes conclusions after examining these transects. Sixty were reclassified based on crew experience. In some cases, this reflects discrepancy between interpretation of terrain from imagery; in others, classification is ambiguous because over the course of a 12 km transect, terrain is so variable to that it was not a simple matter to evaluate the ability of a typical crew to complete it. The remaining 89 anomalous transects were not reclassified, because earlier experience indicated that most crews would use the original completion strategy. The 60 transects that were reclassified represent only 2.1% of the 2786 transects evaluated since 2008, so this had very little impact on our estimate of the proportion of each stratum that is walkable.

Table 8. Transects completed other than as planned and any resulting reclassification

Previous substratum	Situation	New substratum	Number of transects
12k	Shortened in 2012, contradicting previous experience. In many cases, shortened on military base for non-terrain issues	12k	30
12k	On-the-ground observation differs from imagery	Shortened	25
12k	Crew attempted the transect but couldn't walk at least 6km	Unwalkable	1
Shortened	On-the-ground experience indicates walkable though rugged	12k	21
Shortened	Lengthened or replaced as unwalkable in 2012, but not enough evidence to override previous crew experience	Shortened	59
Shortened	Crew planners considered unwalkable; reexamination of topo maps matches their interpretation	Unwalkable	6
Unwalkable	On-the-ground experience contradicted imagery	12k	1
Unwalkable	On-the-ground experience contradicted imagery	Shortened	6

AR060140

Number of tortoises based on density and area sampled

The proportion of each stratum represented by distance sampling is calculated as the proportion of planned kilometers that can be walked (Column 3 in Table 9). This proportion is calculated based on all transects evaluated since 2008. Table 9 reports the area of each stratum, the proportion covered by our density estimates, and the associated estimate of tortoise abundance.

Table 9. Estimated tortoise abundance in sampled areas of each stratum

Stratum	Area (km^2)	Proportion sampled	SE(Prop. Sampled)	Sampled area	N (number of tortoises)	95% Confidence Interval

Possibility of using burrow counts to estimate tortoise abundance at smaller scales

Crews examined 12,817 burrows as they collected tortoise observations to arrive at this estimate of N. Because there was different effort (kilometers walked) in each stratum, Figure 17 plots the relationship between cover sites and tortoise abundance as their standardized measures (burrows per kilometer walked *versus* tortoise density). Although some association is apparent it is not a linear one; without the cluster of poorly sampled strata in the lower left of Fig. 17, no association is apparent at all. This is not entirely surprising, although it is worth exploring whether the associate is accurate at smaller spatial scales. In the Colorado Desert, Krysik (2002) has shown that a strong association exists for 9 km^2 plots in a square study area that is 7 km on a side, but is broken when the plots are 64 km apart. Meanwhile, in areas where burrows are in caliche, not dirt, the mechanism for any association (e.g., more desert tortoises construct and maintain more burrows) does not exist, so for either small or large areas with predominantly caliche caves, the associations are not expected to hold up. This is clearly a topic that should be addressed with additional data and at different scales.

AR060141

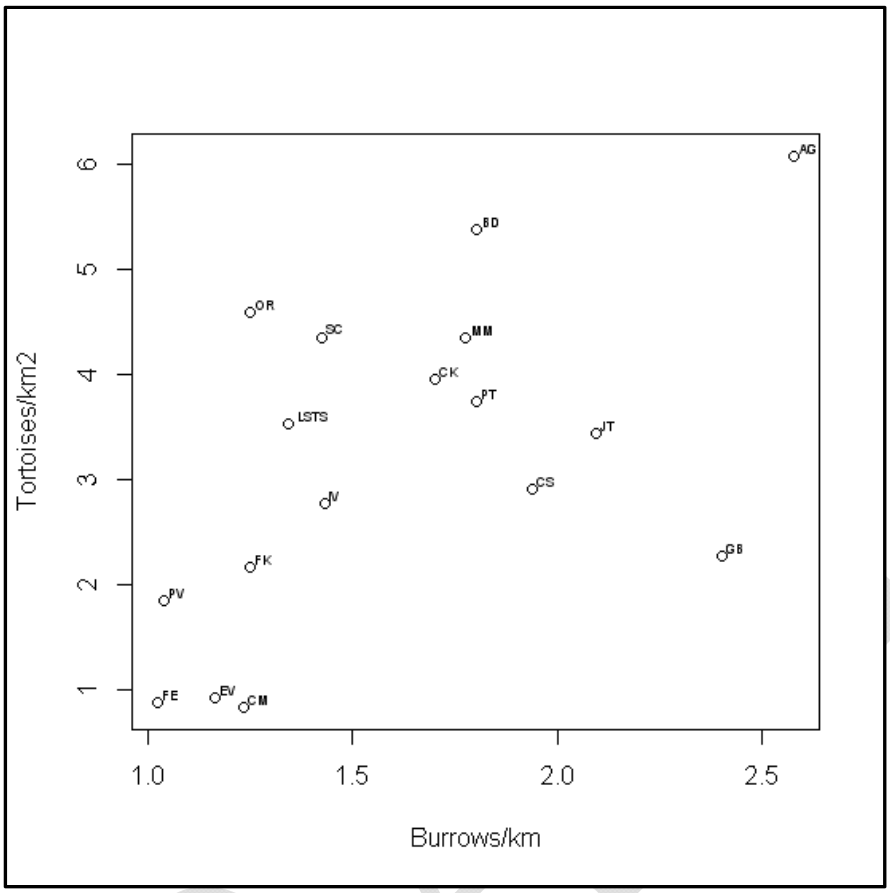

Figure 17. Scatter plot of stratum densities and burrow encounter rate.

Debriefing to identify strengths and weaknesses in preparation for future years

This meeting was held on 31 May, about 1 week after the last field work was completed. Crews were generally well prepared and appropriately addressed any complications in transect and telemetry work. The following issues were identified to be addressed by coordinated effort rather than by efforts of single parties.

Earlier review of the first field data

This was a consistent complaint of crews – that they did not get it in a timely manner, at all, or it did not address their work. There were issues with specialists and USFWS schedules that created unique timing problems this year, but in any year it would helpful to circulate copies of the assessments during training so crews know ahead of time the type of review they will see.

Training improvements to make more effective use of same time period

In general, crews felt they received the appropriate amount of preparation (list of goals) for each training day and their work was reviewed effectively. However, 2 or 3 days of practice transects were completed at the LSTS and crews felt the transects should have been reviewed as if it were the regular field season.

AR060142

To avoid conflicting advice from experienced personnel attempting to fill in gaps in the written information, it was suggested that a FAQ and/or step-through list be created for 2013 G_0. For instance, the book and training should be clear that seeing more tortoises is a priority over having more observations of a small number of tortoises. What should be reported when the tortoise's behavior was apparently in response to seeing the technician first? How often should recently transmittered tortoises be tracked and how should this be documented in our G0 database so that these animals are not included in analyses?

Photos taken on transects should be incorporated in training to illustrate terrain and burrow types not encountered during the pre-season.

DISCUSSION

Quality control and quality assurance

Electronic data collection devices were purchased before the 2011 field season, reducing equipment-related errors, and these were still performing as well or better in 2012 due to greater care with batteries. In addition, the project continued to rely on extensive and intensive feedback to crews and to data specialists during training and the field season. The training emphasis was on review of paper datasheets and standardization of rules for modifying records and documenting these changes. Data managers involved in the final stages of data processing were used to train crews involved in data collection. When project rely on large numbers of relatively independent data collection crews, this sort of standardization reduces identifiable and unidentifiable errors in the final database. The 2012 database products were comparable to those in 2011, with a marked decrease in the number of errors passed through from the field teams to independent reviewers.

Improving ability to detect trends in desert tortoise abundance

The primary goal of the monitoring program is to provide population estimates that are relevant to the recovery plan criteria (USFWS, 2011). The priority for this and every field season is therefore to improve ability to detect trends in desert tortoise abundance at the recovery unit level.

Consequences of insufficient transects

Estimates of tortoise visibility (G_0) were relatively low in the eastern part of the range; associated with this, encounter rates were the lowest that have been reported on this project (under 4 per 100 km walked in all recovery units), but adequate funding in some portions of the range allowed for sufficient transects to nonetheless detect several tortoises per stratum. In 10 of the 16 surveyed strata, fewer than 10 tortoises were detected; this is a rough lower limit for the number of observations to develop an adequate density estimate (Buckland et al. 2001). None of

AR060143

the stratum estimates are meant to stand on their own, and will either be used in combination with other stratum estimates in the same recovery unit (in annual reports such as this one) or with other years of estimates from the same stratum to describe trends; however, the dramatic loss of funding for transects BLM lands in California resulted in such reduced effort and detections that these stratum estimates should probably not be used in any aggregated for either. One way to better utilize available funds is to refrain from sampling in areas without at least a minimum level of funding. Instead of using annual recovery unit estimates to develop trends, description of recovery unit trends will be based on average trends within strata in that recovery unit. Missing years of information should be avoided if it is an important goal to describe annual recovery unit abundance, requiring representation of all associated strata. However, infrequent years of missing data do not prevent trends in individual strata from being described.

Although Anderson and Burnham (1996) targeted CVs between 10 and 15% in each recovery unit, this would be unusually high precision for such an estimate of wildlife abundance. In 2012, 3 recovery units had CVs between 20 and 29% of the density estimate – satisfactory for an annual estimate. The Eastern Mojave Recovery Unit had a density estimate of much lower precision (60.5 %). This is not surprising given the lack of investment in these strata, but is of less concern than the small number of tortoise observations (n=8) on which the density estimate for these 3700 km^2 is based.

Subject: Planning Project Notice, APN 0607-231-11, Joshua Tree Solar Farm, San Bernardino County, California

Dear Ms. Creason:

The County of San Bernardino (County) is considering the issuance of a conditional use permit to allow for the construction and operation of a photovoltaic generating facility on 10 parcels totaling 115 acres at the former Hi Desert Airport. The U.S. Fish and Wildlife Service (Service) supports the development of alternative energy sources, including solar energy. We fully recognize the importance of such development to both the Nation's economy and the global environment. Any form of economic development, however, including that of renewable energy, comes with certain environmental responsibilities. The purpose of this letter is to inform the project proponent of its responsibilities and potential liabilities associated with the renewable solar energy projects under the natural resource protection laws administered by the Service and to provide the County with our recommendations that would facilitate the component's compliance with these Federal laws.

The Service holds certain resources in trust for the American people; these resources include migratory birds and federally listed threatened and endangered species. The Service administers natural resource protection laws germane to solar energy production and transmission. These statutes include the Migratory Bird Treaty Act (16 U.S.C 703 *et seq.*), the Bald and Golden Eagle Protection Act (16 U.S.C. 668-668d.), and the Endangered Species Act (16 U.S.C. 1531 *et seq.*).

Studies on wildlife and solar-energy facilities are limited; however, recent information collected at solar facilities indicates that wildlife, particularly avian species, can be negatively affected by solar-energy development. For example, birds and bats collide with solar panels, mirrors, fences, and ancillary buildings. Birds exposed to elevated levels of solar flux may die as a result of damage to their feathers and internal organs. The construction of solar facilities also destroys large amounts of habitat for wildlife.

The Service would like to help the County make informed decisions in siting, constructing, and operating solar facilities to reduce impacts such as those mentioned above and to ensure the proponent is aware of the potential for liability associated with Federal environmental laws. We offer the following comments to assist you in your planning efforts.

Endangered Species Act

We have discussed this proposed project with NextEra Energy Resources (NextEra) and its consultants in the past. We understand that NextEra has surveyed the site for individuals of the federally threatened desert tortoise (*Gopherus agassizii*) in the past and is planning additional surveys this year. To date, desert tortoises have not been observed on the project site. If desert tortoises are present, the Service would recommend that the County require NextEra to apply for an incidental take permit, pursuant to section 10(a)(1)(B) of the Endangered Species Act, as a condition of your project approval. The County and NextEra should be aware that the process of applying for an incidental take permit under the authorities of section 10(a)(1)(B) of the Endangered Species Act would likely require at least 12 months to complete.

To ensure that the County and NextEra are fully aware of the prohibitions regarding the federally listed animals, included is information regarding section 9 of the Endangered Species Act herein. Section 9 prohibits the "take" of listed animal species. "Take" is defined by the Endangered Species Act as to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or to attempt to engage in any such conduct. "Harm" is an act that kills or injures wildlife. Such act may include significant habitat modification or degradation that actually kills or injures wildlife by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering (50 Code of Federal Regulations 17.3). "Harass" is defined as an intentional or negligent act or omission that creates the likelihood of injury to listed species by annoying it to such an extent as to significantly impair normal behavior patterns which include breeding, feeding, or sheltering (50 Code of Federal Regulations 17.3). Service may provide an exemption from the take prohibitions through the issuance of a biological opinion for Federal actions (section 7 of the Endangered Species Act) or of an incidental take permit for non-Federal actions (section 10(a)(1)(B)). Absent the Service's provision of an exemption or permit, such take could result in prosecution.

Our final comment with regard to the desert tortoise is that, regardless of the measures included in the conditional use permit, the solar site would likely provide some subsidies to common ravens (*Corvus corax*) in the form of shelter and perching sites. Common ravens are effective predators of desert tortoises and will fly long distances to obtain food and water. The project site is within occupied habitat of desert tortoises; consequently, common ravens that perch and shelter within the boundaries of the proposed projects would likely forage in adjacent habitat where desert tortoises reside. We consider this potential augmentation of the number of common ravens and increased predation pressure on desert tortoises to be a significant impact of the proposed project and recommend that the County require NextEra to participate in the regional comprehensive management plan for common ravens through the payment of the per-acre fee, in addition to the implementation of the proposed measures to reduce the attractiveness of the

project site to common ravens. All fees collected under this program would be used by the Desert Managers Group to manage common ravens in the California desert with the goal of reducing their predation on desert tortoises.

Migratory Bird Treaty Act

The development of the proposed facility would result in the loss of approximately 115 acres of desert scrub habitat that supports breeding and foraging of migratory birds. Additionally, we are aware that many migratory birds have died in association with commercial scale solar fields. For example, migratory water birds have landed at solar facilities in the desert, perhaps mistaking the sites for water bodies. Because certain species of water birds, such as grebes, loons, and some species of ducks, cannot take flight unless they are in water, at least some of the birds that land within solar plants will most likely die. Carcasses of other bird species have been found in association with solar panels, fences, and ancillary building at solar facilities.

The Migratory Bird Treaty Act protects most native species of birds in the United States, including those likely to occur in the project area; you can find a list of species protected by the Migratory Bird Treaty Act at: http://www.fws.gov/migratorybirds/regulationspolicies/mbta/mbtandx.html. The Migratory Bird Treaty Act is the cornerstone of migratory bird conservation and protection in the United States and implements four treaties that provide for international protection of migratory birds.

The Migratory Bird Treaty Act prohibits the "take" or possession of protected species of migratory birds. Under the Migratory Bird Treaty Act, take means to pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to pursue, hunt, shoot, wound, kill, trap, capture, or collect (50 Code of Federal Regulations 10.12).

The Migratory Bird Treaty Act is a strict liability statute, meaning that proof of intent, knowledge, or negligence is not an element of a violation of this statute. The statute's language is clear that an action resulting in the "taking" of an individual of a protected species is a violation of this law. The Migratory Bird Treaty Act does not specifically authorize the incidental take of migratory birds; consequently, the Service does not issue permits authorizing such take. In the absence of a permit from the Service, the temporary or permanent possession of protected migratory birds and their carcasses is also a violation of the Migratory Bird Treaty Act.

The Service carries out its mission to protect migratory birds by fostering relationships with entities that have taken effective steps to avoid take, by encouraging others to implement measures to avoid take, and through investigations and enforcement when appropriate. Companies are encouraged to work closely with the Service to identify available protective measures when developing project plans to safeguard wildlife and to implement those measures where applicable. Companies are also strongly encouraged to apply for permits authorizing otherwise prohibited activity, including special purpose utility permits. For this proposed action, NextEra may need to apply for a special purpose utility use permit from the Service. We discuss

this permit with regard to migratory birds later in this letter. Ultimately, those parties involved with the planning, design, construction, operation, maintenance, and decommissioning of projects are responsible for conducting relevant evaluations of the area and for determining, which, if any, bird species may be effected and for seeking and obtaining necessary permits to avoid liability.

Given the potential impacts that the proposed project may have on migratory birds, we recommend that NextEra develop a bird conservation strategy that includes a robust, systematic monitoring protocol to document mortality and habitat effects to birds that incorporates the following three objectives: an estimation of the overall annual avian mortality rate associated with the facility, including mortality associated with all the features of the project that are likely to result in injury and mortality (e.g., fences, ponds, solar panels); a determination of which species are killed at the facility during different times of the day (i.e., during the day vs. night); and a determination of whether mortality rates differ within the solar field (i.e., panels on the edge vs. the interior of the field). We recommend that this protocol address the efficiency of searchers and the rate at which carcasses disappear from the site; absent these components, the results of the mortality monitoring will not present a realistic estimate of the numbers of birds that die within the solar arrays. The bird plan should also include an adequate spectrum of adaptive management measures to avoid and minimize the effects of the facility's operations on bird populations. We recommend that NextEra implement the monitoring program for a minimum of two to three years; if numerous birds die as a result of operation of the project, we would recommend that the duration of monitoring be extended until NextEra can demonstrate that its adaptive management strategy is effectively reducing the number of mortalities. This type of information will be helpful in developing best management practices to minimize adverse effects to birds and address concerns on the potential for cumulative effects.

A bird conservation strategy is not a substitute for complying with the Endangered Species Act, Migratory Bird Treaty Act, or other applicable laws. We encourage NextEra to coordinate development of its bird conservation strategy with the Service during the project-planning phase to ensure the minimization measures and monitoring plan are sufficient.

The development and implementation of a bird conservation strategy to avoid take of migratory birds does not limit or preclude the Service from exercising its authority under any law, statute, or regulation if migratory birds are taken by any structures associated with the proposed solar facility. However, our Office of Law Enforcement focuses its resources on investigating and prosecuting those individuals and companies that do not identify and implement all reasonable, prudent and effective measures to avoid the take of migratory birds (including eagles) and then subsequently take individuals of such species. Ideally, a high quality, scientifically valid, and robust bird conservation strategy that is implemented in a timely and effective manner, and regularly reviewed and revised as needed, can result in the Service regarding such actions as appropriate means to avoid take of species protected under our various laws while allowing for project development in the most environmentally conscientious manner practicable.

If NextEra intends to collect the carcasses of birds, it would need to apply for a special purpose utility permit from the Service to ensure compliance with the Migratory Bird Treaty Act. The County may wish NextEra to collect carcasses to facilitate its monitoring efforts, to avoid attracting scavengers (e.g., common ravens, which also prey on desert tortoises), and to reduce the potential for human health issues. If the County determines that it would like NextEra to collect carcasses, we strongly encourage beginning the process to obtain a special purpose utility permit, which includes developing an acceptable plan to monitor the mortality of birds at the facility, early enough to allow us to issue a permit prior to the onset of construction. The application for this type of permit can be found at http://www.fws.gov/forms/3-202-17.pdf.

Because the development of numerous solar facilities in San Bernardino County and throughout the California desert, we recommend that the County addresses the cumulative impact of the development and operation of these solar facilities in the desert on migratory bird populations and their habitat. Specifically, the Service recommends that the County include a requirement in the conditional use permits for NextEra to mitigate for the loss of this habitat for migratory birds. Possible mitigation could include contributing to a fund to investigate the regional and cumulative effects of the loss of habitat for migratory birds, identifying and reducing sources of mortality, and enhancing habitat. We are willing to work with you and NextEra to develop and implement appropriate mitigation; one of the regional joint ventures that the Service has established for the conservation of migratory birds may have programs in place that would facilitate the implementation of such mitigation. A joint venture is a collaborative, regional partnership of government agencies, non-profit organizations, corporations, tribes, and individuals that conserves habitat for priority bird species, other wildlife, and people. More information on joint ventures is available at:
http://www.fws.gov/birdhabitat/JointVentures/index.shtm.

We appreciate the opportunity to participate in your planning process. We also appreciate the fact that NextEra has proposed to construct this solar facility on a site that has been disturbed by past uses. If you have any questions regarding these comments, please contact Ray Bransfield of my staff at (805) 644-1766, extension 317.

Sincerely,

Kennon A. Corey

SUBJECT: Consultation pursuant to section 7(a)(2) of the Endangered Species Act of 1973, as amended, with regard to development of an alternative energy project on Fort Irwin.

Dear Ms. Noda,

The Army requests to initiate formal consultation under 50 CFR § 402.16(b) with the US Fish & Wildlife Service with regard to its proposed development of an alternative energy project on Fort Irwin.

The Army proposes to construct and operate a solar photovoltaic (PV) facility on up to 380 ac. The facility would include solar arrays, access/maintenance roads, an electrical tie-in, a transmission line corridor, and potentially a battery energy storage system. This project is part of a Department of the Army program to address threats to the power supply to its installations from stochastic events such as accidents, terrorist attacks, and disruptive natural events such as fire and wind storms. The project also supports federal agency requirements for increasing energy consumption from renewable sources while reducing greenhouse gas emissions.

Initial surveys of the project site showed the presence of a small population of Desert Tortoises with 3 extant tortoises identified within the proposed project area. Fort Irwin, acting as the lead federal agency, has determined that the proposed project may affect and is likely to adversely affect the desert tortoise, but would not jeopardize the continued existence or recovery of the desert tortoise. The proposed project would not adversely modify or destroy designated critical habitat for this species.

No other species protected under the ESA would be affected by the proposed action. Information contained in the attached BA is not to be released outside of the FWS without the permission of the lead agency. The Army requests an expedited 90-day review for the BA, if possible, to support the development of this critical renewable energy initiative.

Fort Irwin

Fort Irwin National Training Center Solar Facility Project

Final Biological Assessment

United States Army
National Training Center and Fort Irwin
San Bernardino County, California

September 2012

Summary of Findings, Conclusions, and Determinations

The National Training Center at Fort Irwin Military Reservation in San Bernardino County, California, is proposing to construct and operate a solar photovoltaic (PV) facility on up to 380 acres (ac). The project would include the construction of the following:

- PV modules/panels
- Solar trackers (to position modules with the sun's movement) or fixed-tilt mounting structures
- Direct current-to-alternating current inverters
- Three-phase, pad-mounted medium-voltage transformers, or similar; and high-voltage step-up transformers
- Transmission line extending from the solar facility to North Loop Road
- Permanent exclusion fencing around the solar facility

The project would generate reliable back-up power, reduce consumption of non-renewable energy, and reduce combustion emissions.

Federally Listed Species

Federally listed threatened, endangered, and proposed species were evaluated to determine their potential presence within the action area. The desert tortoise (*Gopherus agassizii*), a federally listed threatened and state listed threatened species, received detailed consideration because documented observations of this species have been recorded within the action area.

Project Effects

Project-related construction will directly affect desert tortoise through permanent loss of habitat, as well as potential harassment or harm of individuals should clearance surveys determine that relocation of individuals will be necessary. Operation of the solar facility and the associated transmission line would not be expected to affect desert tortoise. Maintenance activities within the solar facility would not affect desert tortoise due to the presence of the exclusion fencing. Maintenance activities along the transmission corridor could affect desert tortoise through harassment, injury, or mortality as a result of vehicle and equipment activity in the transmission corridor, as it would not have permanent exclusion fencing.

Project construction and operation would result in approximately 380 ac of permanent effects to desert tortoise habitat. Project components generally include construction, operation, and maintenance of the solar facility site, a transmission line, and construction and operation and maintenance of other related components. The project is within the Western Mojave Recovery Unit but does not lie within a Desert Tortoise Critical Habitat area or a Desert Wildlife Management Area. The Superior-Cronese critical habitat unit is less than 5 miles west of the action area. The project would not result in fragmentation of the desert tortoise critical habitat and would not adversely modify or destroy desert tortoise critical habitat. The project would not affect any other federally listed threatened, endangered, or proposed plants or wildlife.

Avoidance and Minimization Measures

Fort Irwin has designed the project to minimize direct effects to the desert tortoise and its habitat. In addition, Fort Irwin will employ best management practices (BMPs) in order to avoid, minimize, and prevent any potential direct effects to desert tortoise or potential habitat. These measures include:

- Clearance surveys will be conducted after placement of exclusion fencing and prior to construction activities.
- An Authorized Biologist will be onsite during initial site grading activities and any subsequent construction activities that would have the potential to affect desert tortoise. If a desert tortoise is found within or adjacent to the project site during construction or operation, an Authorized Biologist will move it out of harm's way in coordination and consultation with the United States Fish and Wildlife Service.
- An erosion and sediment control plan will be implemented as part of standard Fort Irwin BMPs to prevent project-related construction effects on habitat outside the work areas.
- The action area perimeter, including support facilities, will be surrounded by desert tortoise exclusion fencing during construction. Controlled access gates will be installed at roads entering or exiting the solar farm site. The Project site will be designed, operated, and maintained so that channelization of surface water flow will not undermine the integrity of the perimeter fence or the desert tortoise exclusion fencing.
- The perimeter of the operational solar facility will be surrounded by permanent desert tortoise exclusion fencing. This area may be less than the action area fenced during construction.
- Clearance surveys will be implemented prior to maintenance activities along the transmission corridor during operation because of the potential for desert tortoise to enter this area and be injured or killed by operation of equipment within the transmission corridor.

Cumulative Effects

Cumulative effects are those effects of future state or private activities, not involving federal activities, that are reasonably certain to occur within the action area of the federal action subject to consultation (50 Code of Federal Regulations §402.02). This definition applies only to Section 7 analysis, and should not be confused with the broader use of this term in the National Environmental Policy Act, or other environmental laws.

No other projects are currently planned in the action area. Consequently, no non-federal projects would contribute to cumulative effects. Because no additional non-federal projects occur in the area, this project would not contribute to cumulative effects.

Finding of Effect

Based on the information discussed through technical assistance with resource agencies, data collected for and presented in this Biological Assessment, and the planned implementation of the avoidance and minimization measures, Fort Irwin has determined that the proposed project would have the following effects:

- Fort Irwin, acting as the lead federal agency, has determined that the proposed project **may affect and is likely to adversely affect the desert tortoise, but would not jeopardize the continued existence of** the desert tortoise.
- The proposed project would **not adversely modify or destroy** designated critical habitat for this species.

No other species protected under the Federal Endangered Species Act would be affected by the proposed action.

1 Introduction

The purpose of this Biological Assessment is to evaluate the potential effects of the Fort Irwin Solar Facility (Proposed Action) on the federally threatened Mojave population of the desert tortoise (*Gopherus agassizii*) (United States Fish and Wildlife Service [USFWS], 1990 [55 Federal Resister (FR) 12178]) and designated critical habitat for this species and to determine whether the species or its habitat are likely to be adversely affected by the action.

This BA will:

1. Provide a conceptual framework of the history of the project, including the legislative action for the withdrawal and reservation of lands and relationship to other actions and processes.
2. Document the evolution of project consultations with the USFWS.
3. Describe the proposed action, including the planned use and all proposed mitigation and conservation measures.
4. Provide detailed information on the natural history of federally listed endangered or threatened species, or species proposed for listing potentially occurring in the vicinity of the project.
5. Evaluate the potential effects of the Proposed Action on federally listed or proposed listed endangered or threatened species and any designated critical habitat for these species.
6. Provide a determination of effect ("no effect," "may affect, not likely to adversely affect, or modify critical habitat," or "may affect, is likely to adversely affect, or modify critical habitat") for the listed and proposed-listed species.

1.1 Project Background

The U.S. Army National Training Center (NTC) at Fort Irwin is located approximately 37 mi northeast of Barstow, California, in the north-central region of the Mojave Desert (Figure 1-1). Fort Irwin is approximately 25 mi from Interstate 15 midway between Las Vegas and Los Angeles. The Fort Irwin reservation encompasses over 755,000 acres (ac), with approximately half of this land used for desert battlefield training. The Superior-Cronese critical habitat unit for desert tortoise extends into the southern and southwestern portions of Fort Irwin (Figure 1-1).

Fort Irwin serves as the Army's premier training center. The NTC is the premier training center for heavy combat maneuver forces. The mission of the NTC is to provide U.S. and allied forces with tough, realistic, joint and combined arms training across the full spectrum of conflict to assist Commanders in developing trained, competent leaders and soldiers prepared for success on future joint battlefields. Fort Irwin has a resident population of approximately 4,500 soldiers and their families. In addition, approximately 4,000 to 6,000 soldiers visit Fort Irwin during training rotations, which occur 10 times a year. A cantonment area occupies approximately 14,000 ac of the installation and provides temporary and permanent living quarters for soldiers and their families. The cantonment area consists of residential areas, support facilities, retail centers, restaurants, and health care facilities.

1.2 Summary of Consultation to Date

Fort Irwin has completed consultation with USFWS regarding potential effects to desert tortoise on multiple occasions. This section discusses past consultations regarding desert tortoise that may be relevant to this Biological Assessment.

On September 15, 1995, USFWS issued a Biological Opinion (BO) on the Army mission at Fort Irwin which determined that the Army mission would not jeopardize the continued existence of the species or adversely modify critical habitat. The BO included an incidental take statement for military training activities and Reasonable and Prudent Measures (RPMs) and Terms and Conditions (T&Cs) that the Army would implement to minimize incidental take associated with training activities. The September 15, 1995 BO superseded a previous non-jeopardy BO dated September 24, 1991.

On May 31, 2002, USFWS issued a BO for the proposed installation of an off-road vehicle (ORV) use area located near the cantonment area. The ORV area, located approximately 4.5 miles south-southwest of the Military Police Station at the center of the cantonment area, overlaps the proposed Fort Irwin Solar Facility project area and is used by military personnel and their dependents during leisure time. The BO determined that the ORV use area is not located within critical habitat for the desert tortoise and is not likely to jeopardize the continued existence of the desert tortoise. The BO included an incidental take statement for the ORV use area that the Army would implement to minimize incidental take and to promote conservation of the species.

The Army had considered expansion of Fort Irwin since the 1980s. Between 1991 and 2003 there were multiple consultations on different expansion proposals. On March 15, 2004, USFWS issued a BO for the addition of maneuver training lands at Fort Irwin with a determination that the addition of training lands at Fort Irwin was not likely to jeopardize the continued existence of desert tortoise and Lane Mountain milk-vetch or to destroy or adversely modify critical habitat of the desert tortoise. This BO concluded a multi-year consultation that included revisions to the proposed expansion and inclusion of conservation actions. As a result of this consultation, the Army implemented numerous measures for the conservation of desert tortoise and Lane Mountain milk-vetch, which included:

- Establish three desert tortoise conservation areas within Fort Irwin.
- Establish a 500-meter (m) buffer for desert tortoise along the Boulder Utility Corridor.
- Establish two conservation areas for Lane Mountain milk-vetch.
- Place 1,872 ac of Lane Mountain milk-vetch habitat in the Brinkman Wash-Montana Mine population in a larger no-dig zone.

The conservation areas had no mechanized training, no ground disturbance, and no off-road activity. Vehicle travel had been limited to existing roads, and new roads were created only if needed for conservation management. Aircraft and helicopter overflights were permissible within the limits of airspace restrictions, but no landings were allowed. In the no dig zone, in addition to a prohibition on digging, only dismounted troop maneuvers were allowed and no tactical assembly areas or brigade support areas were allowed.

Subsequent to the March 15, 2004 BO and consistent with the consultation, the U.S. Geological Survey (USGS) developed a plan to guide the translocation of desert tortoises from the Fort Irwin southern expansion area. During the development of the translocation plan, the USGS determined that moving desert tortoises from the southern expansion area to areas directly south of Fort Irwin would be more appropriate than moving them farther away to an area that seemed to have undergone a major decrease in the density of desert tortoises. Because this course of action was substantially different than the one discussed in the 2004 BO, the USFWS issued a re-initiated BO (1-8-05-F-43) on December 29, 2006, that addressed the different translocation strategy, the installation of a desert tortoise-proof fence along Interstate 15, and the construction of pens to hold translocated desert tortoise.

On May 21, 2009 the Army requested reinitiation of formal consultation because the number of desert tortoise found in the southern expansion area exceeded that predicted in the previous BO and because new information regarding elevated levels of predation of translocated desert tortoises became available. Subsequently, the Bureau of Land Management (BLM), which was part of a joint Conservation Mitigation Working Group that also included USFWS, the Army, and the California Department of Fish and Game, determined that its proposed action to allow the Army to release desert tortoise from Fort Irwin onto public lands in the western translocation area was likely to adversely affect the desert tortoise. USFWS determined that the BLM proposed action was likely to adversely affect the desert tortoise in the same manner as the translocation portion of the Army proposed action and determined that it was appropriate to issue a single BO to both agencies.

On July 30, 2009, USFWS provided the Army and BLM a draft BO. The Army provided comments on the draft BO and BLM made the draft BO available for public review as part of the National Environmental Policy Act review for its proposed action of allowing the Army to use public lands for the translocation of desert tortoise. USFWS also received comments on the draft BO from the Center for Biological Diversity, Public Employees for Environmental Responsibility, and Desert Survivors. The Western Watersheds Project commented on the BLM environmental assessment with regard to the draft BO. BLM withdrew from formal consultation on September 21, 2009 and the Army withdrew from formal consultation on September 20, 2010 due to cancellation of the fall desert tortoise translocation. Subsequently, the Army requested reinitiation of formal consultation on January 20, 2011 for an action involving multiple Federal agencies, but for which the consultation and conference responsibilities would be fulfilled by the Army (NTC) as the lead agency in accordance with 50 Code of Federal Regulations (CFR) 402.07. The request for reinitiating formal consultation was based on (1) the increase in the number of desert tortoise found compared to the number analyzed in the original BO and (2) the fact that the original BO was issued prior to the Ninth Circuit Court's decision that invalidated the USFWS regulatory definition of "destruction or adverse modification of critical habitat" at 50 CFR 402.02.

USFWS considered the comments received on the draft BO and incorporated them into its final BO of April 27, 2012, as appropriate. The April 27, 2012 BO for the addition of maneuver training lands at Fort Irwin determined that the proposed action was not likely to jeopardize the continued existence of the desert tortoise and that, while approximately 2.4 percent of the Superior-Cronese Critical Habitat Unit would be adversely affected by subsequent training activities, the action was not likely to adversely modify or destroy critical habitat of the desert tortoise. The BO included an incidental take statement for military training activities and RPMs and T&Cs that the Army would implement to minimize incidental take and to promote conservation of the species.

For the action under consideration in this Biological Assessment, a conference call discussion was conducted on February 15, 2012, with Brian Croft (USFWS, 2012a) regarding desert tortoise presence/absence surveyor requirements and any qualifications that may need to be submitted prior to surveying. Mike Ackerman (US Army Environmental Command) discussed project permitting requirements with Brian Croft on April 29, 2012. Mr. Croft indicated that consultation will be required for the project and mentioned that the USFWS has turned the action over to Erin Nordin in the San Bernardino USFWS office. Mr. Ackerman also spoke with Ms. Nordin regarding the permitting needs for the project. Both USFWS employees indicated that a Biological Assessment with formal consultation would be recommended for the proposed project.

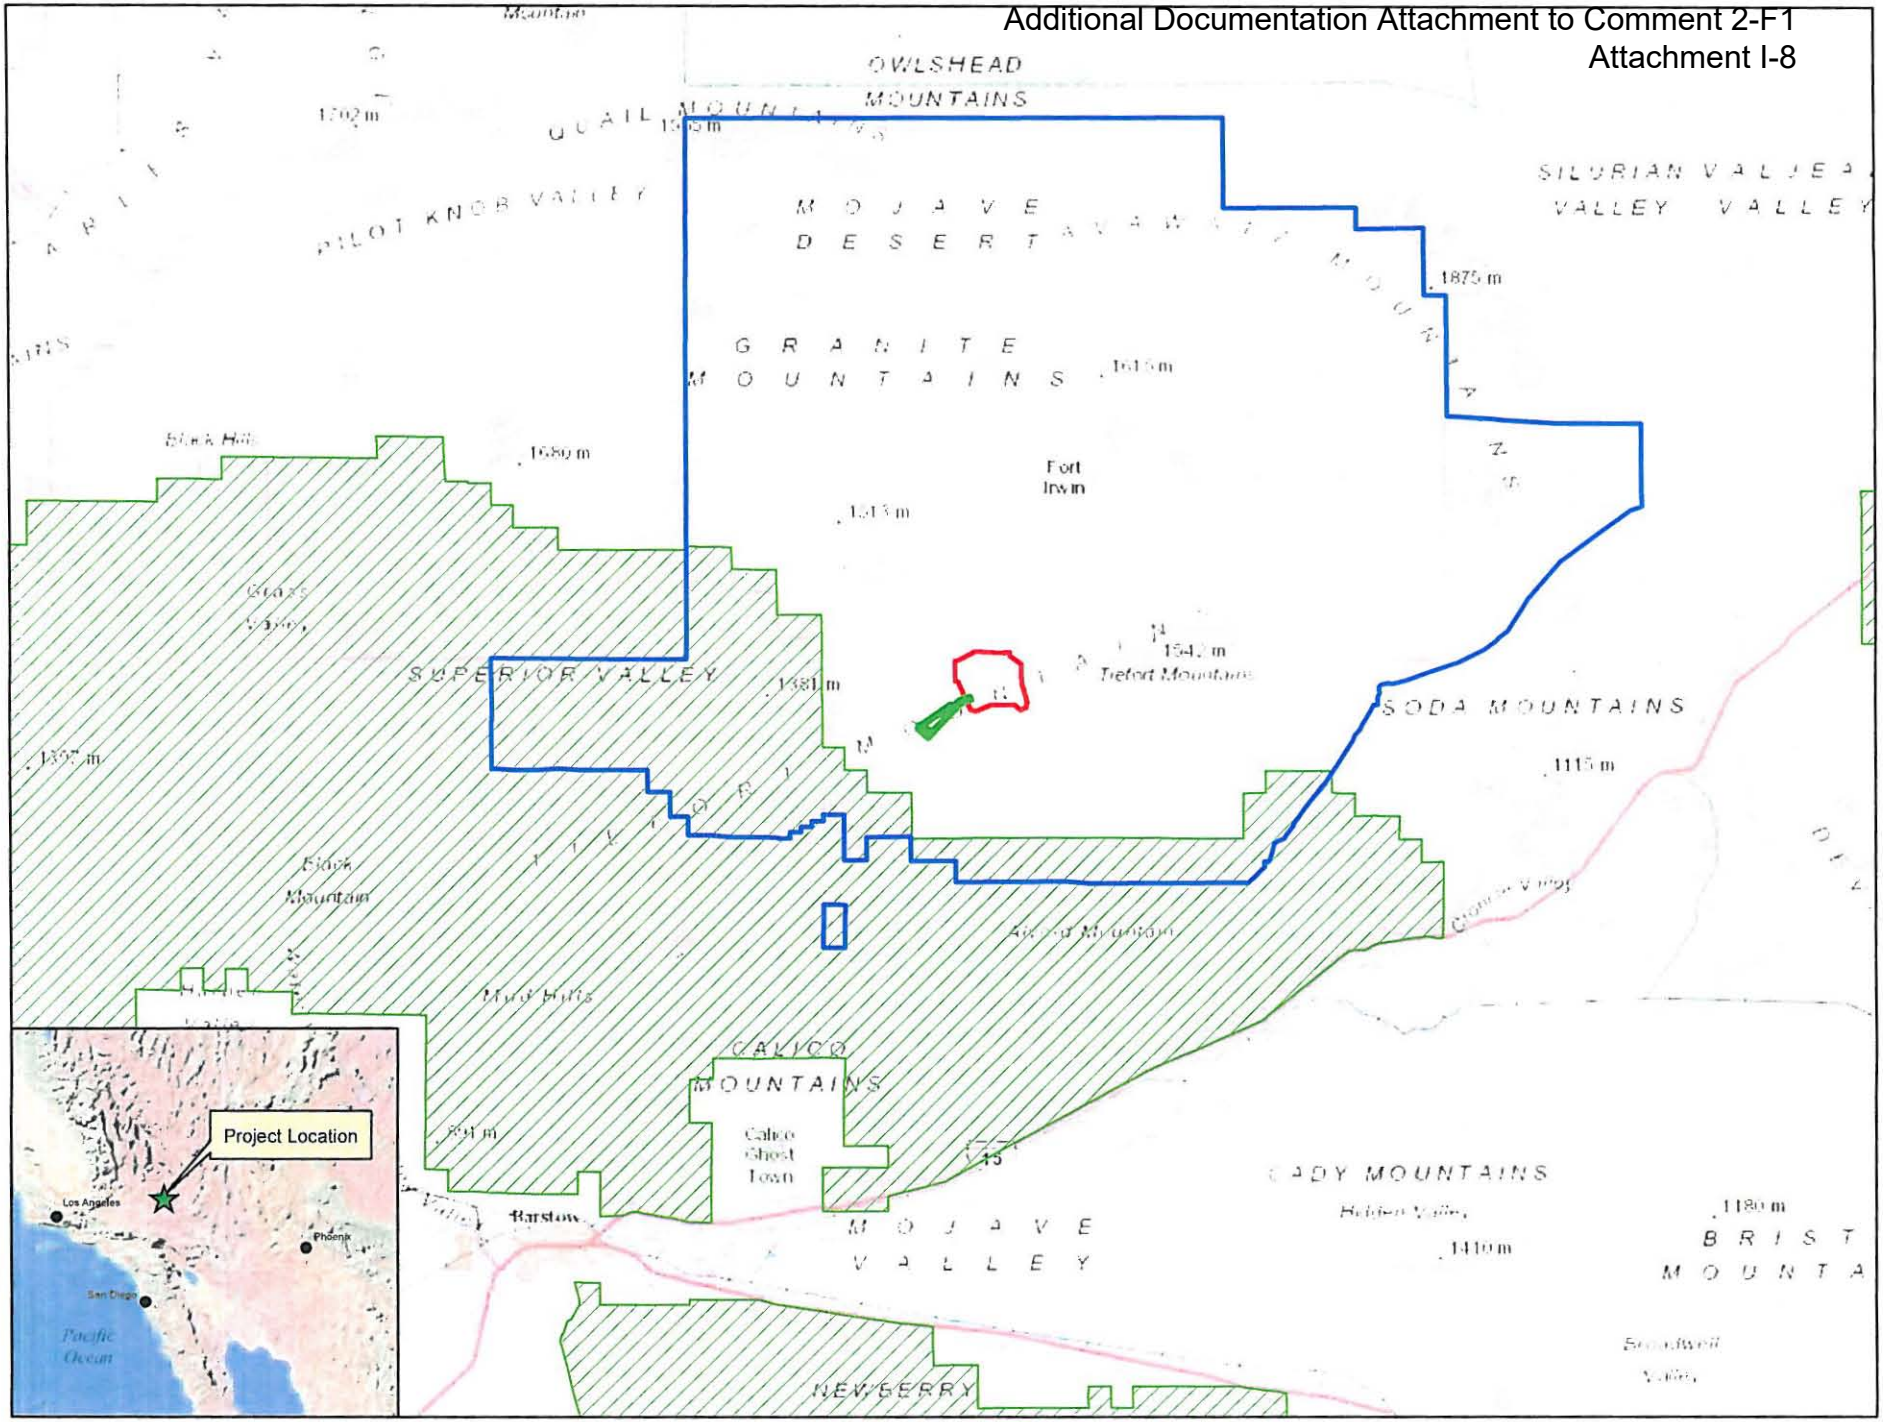

FIGURE 1-1
Desert Tortoise Critical Habitat Area
Fort Irwin National Training Center Solar Facility Project
Natural Resources Report
Fort Irwin, California

AR060166

2 Project Description

Fort Irwin is proposing to construct and operate a solar photovoltaic (PV) facility on up to 380 ac. The facility would include solar arrays, access/maintenance roads, an electrical tie-in, a transmission line corridor, and potentially a battery energy storage system.

2.1 Project Purpose and Need

The project is part of a Department of the Army program to address threats to the power supply to its installations from stochastic events such as accidents, terrorist attacks, and disruptive natural events such as fire and wind storms. The Fort Irwin power supply is vulnerable to disruption. Installation electricity is distributed through a single 30-mile (mi)-long radial 115-kilovolt (kV) power line operated by Southern California Edison (SCE) which, if disrupted, would require the NTC to rely on back-up power generation, resulting in greater amounts of energy consumption and air pollution.

Fort Irwin needs to address the following U.S. Army Senior Energy Council security goals:

- Increase in energy-efficiency across platforms and facilities.
- Increase use of renewable/alternative energy.
- Increase assurance of access to sufficient energy supplies.
- Reduce adverse impacts on the environment.

Fort Irwin must meet the requirements of Congressional legislation and Executive Orders (EOs), including The Energy Policy Act of 2005 (Section 203), EO 13423, EO 13514, the National Defense Authorization Act of 2007, which mandates a 25 percent reduction in the use of nonrenewable energy by 2025, and the Energy Independence and Security Act of 2007, which directs reductions in the use of fossil fuels.

The purpose of the Fort Irwin project is to provide the NTC with enhanced energy security through a protected onsite energy supply to support installation operations and to enhance energy sustainability at the installation.

The Proposed Action would achieve the following objectives:

1. Provide Fort Irwin with a secure and reliable supply of back-up electrical power from a renewable source
2. Meet the goal of 25 percent increased use of renewable energy by 2025

2.2 Action Area

The implementing regulations to Section 7(a)(2) of the Endangered Species Act (ESA) define the action area to be all areas affected directly or indirectly by the federal action and not merely the immediate area affected by the proposed project (50 CFR §402.02). The action area is the area where direct effects from construction and operation (the project footprint) or indirect effects of the proposed action and any interrelated or interdependent human activities may occur. The direct and indirect effects of these activities include associated physical, chemical, and/or biological effects of considerable likelihood. Indirect effects are those that are caused by or would result from the proposed action later in time, but are still reasonably certain to occur. The project is not expected to cause increased amounts of traffic that would result in future increases in light, noise, or vibration disturbances or result in increased potential for traffic mortality.

It is possible that relocation of desert tortoise to the adjacent area and subsequent exclusion of desert tortoise from the solar facility site would result in biological impacts through interaction with other desert tortoise.

Temporary relocation of desert tortoise from the transmission corridor area during construction would not be expected to result in biological impacts because desert tortoise would not be permanently excluded from this area and would be expected to return to it after construction.

Male desert tortoises translocated a short distance move an average of 619 m in the first year following relocation (Walde et al., 2011). Therefore, it is possible that translocated desert tortoise from the solar facility site could reasonably be expected to move up to 619 m to the northwest. Results of the solar facility site survey (Appendix A; CH2M HILL, 2012) indicate that tortoise within the solar facility site already are likely to use a portion of this area, as an occupied burrow was found approximately 100 m within the northwestern boundary of the solar facility site and additional desert tortoise sign were found along and near the northwestern boundary. Because the number of desert tortoise that would be translocated would be small, due to the low desert tortoise density in the solar facility site and the surrounding area, it is unlikely that any biological impacts would result from relocation.

The potential for indirect biological effects is expected to be low in surrounding areas as a result of relocation of desert tortoise and subsequent exclusion of desert tortoise from the solar facility site. No interrelated and interdependent projects are known for this area. Potential indirect effects during construction and operation include storm water runoff from the proposed solar facility site which could affect the immediately surrounding area of the site (discussed further in Section 6.2 of this document). An Erosion and Sedimentation Control Plan and a Storm Water Pollution Prevention Plan (SWPPP) will be implemented to prevent degradation to desert tortoise habitat within and immediately surrounding the construction area. The indirect effect to the desert tortoise from damage to adjacent habitat will be minimized through implementation of these plans. However, other desert tortoise populations may occupy home ranges that overlap the project area. These tortoises could experience indirect impacts from loss of potential habitat.

Therefore, the action area for this project is equal to the area of direct effects and the immediately adjacent area. This includes the 380 ac of desert tortoise habitat that will be affected by the construction of the project, including the solar site, the associated linear facilities (e.g., access roads and transmission line), and related infrastructure. The area for potential operational impacts would not extend beyond the area that will be impacted by construction.

The analyses of environmental baseline, effects of the action on the species and designated critical habitat, cumulative effects, and the impacts of incidental taking, are based upon this action area.

2.3 Project Components

The proposed project is the construction and operation of a PV solar array on approximately 380 ac of land approximately 0.25-mi inside the Fort Irwin main gate. The facility would be 13- to 20-megawatt electrical (MWe) and would connect to existing SCE infrastructure that serves Fort Irwin via a substation adjacent to the proposed project location. A new transmission line would be constructed from the solar facility to existing SCE infrastructure at North Loop Road to provide back-up power to buildings 980, 985, and 988 in the Fort Irwin cantonment area. The final constructed footprint would be approximately 250 ac in size. Construction parking and laydown areas could extend beyond the approximately 250-ac footprint, but would be confined within the approximately 380-ac area.

The major project equipment would include the following:

- PV modules/panels
- Solar trackers (to position modules with the sun's movement) or fixed-tilt mounting structures
- Direct current-to-alternating current inverters
- Three-phase, pad-mounted medium-voltage transformers, or similar; and high-voltage step-up transformers
- Transmission line corridor extending from the solar facility to North Loop Road
- Permanent desert tortoise exclusion fencing

The PV modules, inverters, and transformers would be combined into approximately 1-megawatt (MW) blocks that are repeated to reach the full required capacity (up to 20 MW). Each block would be approximately 500 feet by 700 feet. Trenches for cables would be placed approximately 12 inches underground when needed to connect panel arrays. The solar arrays would be supported in one of three manners depending on wind and geophysical conditions (soils, bedrock, etc.): (1) concrete ballasts set at grade, (2) piles either driven or screwed to a minimum of 4-5 feet in depth, or (3) excavated, cast-in-place concrete footers.

Unpaved access/maintenance roads would be constructed from existing roads to access the site and individual blocks of arrays.

As part of the project plan and for energy security purposes, the PV project would be used to provide power to critical Fort Irwin military facilities during (rare) prolonged outages of the SCE-owned and -operated electrical grid. The PV project would provide power to critical facilities at buildings 980, 985, and 988. The buildings would be connected to a new, "solar circuit" via aboveground or underground conductors installed from the PV project along the north side of Fort Irwin Road that would connect with existing infrastructure upon reaching North Loop Road. An alternative approach to energy security would be to install three portable, 1-megawatt-hour energy storage batteries that would be charged and recharged at the PV facility and trucked to and connected to buildings 980, 985, 988, and/or other buildings in a rotating manner. The PV facility would connect to the Tiefort substation via a 100- to 500-yard electrical tie-in line, which would be installed at or below the height of the existing distribution lines in the vicinity.

Operation of the solar facility would involve limited activity beyond maintenance of the facility (vegetation control, road maintenance, etc.) and annual washing of the solar panels to remove accumulated dust. Water would be trucked to the site to clean the solar panels.

2.4 Construction Methods and Equipment

All temporary use areas and laydown areas would be within the construction footprint. The maximum monthly construction work force would be approximately 145 people. Construction equipment likely to be used includes:

- Scraper
- Motor grader
- Excavator – trench
- Excavator – pier
- Hydraulic ram
- Dozer
- Dump truck
- Pad drum vibratory roller
- 4,000-gallon water truck
- Backhoe loader
- Concrete truck
- Loaders – Bobcats
- Grade-all
- Welders
- Trencher
- Lightweight trucks

Some oversized equipment would be used during construction. However, no equipment would be larger than equipment that is routinely trucked in and out of Fort Irwin on Fort Irwin Road (e.g., tanks).

Prior to construction activities and site clearance survey, high-visibility orange exclusion fencing and desert tortoise exclusion fencing will be installed along the perimeter of the work areas, including the transmission

corridor, to clearly delineate the extent of the construction area. The exclusion fencing will prevent construction encroachment into desert tortoise habitat, as well as excluding desert tortoise from entering the action area. The location of the exclusion fencing will be established in the field by the Authorized Biologist(s). The project's special provisions package will provide clear language regarding fencing installation procedures, acceptable fencing material, prohibited construction-related activities, vehicle operation, material and equipment storage, and other surface-disturbing activities.

Permanent exclusion fencing will be placed around the solar facility at the close of construction and will encompass the minimum area needed for operation and maintenance of the facility. This fencing will prevent desert tortoise from returning to the facility site once it is operational and minimize the potential for inadvertent impacts during operation. During operation of the solar site, routine operation and maintenance activities are expected to be limited to repair of the perimeter fence, access gates, all-weather roads, solar arrays/ module components, support facilities, vehicle and equipment movement, and vegetation removal. Once annually, water would be trucked to the site to clean the solar panels. Use of oversized equipment is not anticipated during operations.

The Authorized Biologist(s) will also obtain required permits before project initiation and prior to handling any desert tortoise or their parts, will conduct clearance surveys within 2 weeks prior of construction to determine the presence of desert tortoise on the site, will conduct all handling and relocation of desert tortoise individuals indentified in the construction area, will train construction workers on desert tortoise regulations and protocols prior to any ground-breaking activities, and will conduct biological monitoring for desert tortoise in the project area during site (or related facilities) mobilization, ground disturbance, grading, construction, operation, and closure activities. The Authorized Biologist(s) will perform these activities to prevent and minimize harm and harassment to desert tortoise individuals during construction and operation of the proposed project. These minimization measures are further discussed in Section 7.2.

An Erosion and Sedimentation Control Plan and a SWPPP will be implemented to prevent indirect effects from degradation to the desert tortoise habitat within and immediately surrounding the construction area. During construction, dust suppression, general housekeeping measures, prohibition of pets in the area, and invasive plant removal will occur to minimize harm and harassment to the desert tortoise and to prevent attracting predators that may harm or harass desert tortoise. These minimization and avoidance measures are further discussed in Section 7.1.

2.5 Construction Schedule

Project construction would likely begin in spring 2013. Construction would last approximately 6 months.

3 Status of Species

3.1 Status of Listed Species

A list of federally endangered and threatened species that may be affected by the proposed project was obtained online from the California Department of Fish and Game (CDFG) California Natural Diversity Database (CNDDB) (CDFG, 2012) and the California Native Plant Society (CNPS) inventory of rare and endangered plants of California (CNPS, 2012). These databases were queried for the USGS Langford Well 7.5-minute quadrangle map, where the project is located, as well as the eight surrounding quadrangle maps. A list of federally listed or proposed wildlife and plant species potentially occurring within the action area (shown in Figure 3-1) was compiled to evaluate potential impacts resulting from project construction. The action area is defined as the areas that would be directly affected by the project, which is the maximum extent of construction-related ground-disturbing activities. Records were reviewed for federally listed species that may occur within the action area.

Two federally listed species, the threatened desert tortoise and the endangered Lane Mountain milk-vetch (*Astragalus jaegerianus*), were identified as having potential to occur within the action area based on habitat suitability and known range (Bagley, 1998; USFWS, 2008).

3.1.1 Desert Tortoise

3.1.1.1 Listing History

The desert tortoise occurs in the Mojave and Sonoran Deserts in southern California, southern Nevada, Arizona, and the southwestern tip of Utah in the U.S., as well as Sonora and northern Sinaloa in Mexico (USFWS, 2012b). The Mojave population of the desert tortoise includes all tortoises north and west of the Colorado River in Arizona, Utah, Nevada, and California (USFWS, 2011a).

In response to the dramatic decrease in numbers of the Mojave population of the desert tortoise throughout its range, the USFWS emergency-listed the species as endangered on August 4, 1989 (54 FR 32326). This listing occurred as a result of continued human-caused habitat destruction through urban expansion, off-road vehicle use, illegal collection for the pet trade, and raven predation on juvenile tortoises. The Mojave population was then proposed under normal listing procedures on October 13, 1989 (54 FR 42270), and subsequently listed as threatened throughout its range on April 2, 1990 (55 FR 12178), when USFWS concluded that listing of desert tortoise was warranted. On March 30, 1993, the USFWS released the *Draft Recovery Plan for the Desert Tortoise (Mojave Population)* (USFWS, 1993). The Final Recovery Plan was released on June 28, 1994 (USFWS, 1994). An additional plan for the desert tortoise, the *Proposed Desert Wildlife Management Areas for Recovery of the Mojave Population of the Desert Tortoise* (Brussard et al., 1994), divided the species' range into six recovery units. In 2011, the *Revised Recovery Plan for the Mojave Population of the Desert Tortoise (Gopherus agassizii)* was published by USFWS. The Revised Recovery Plan reduced the number of recovery units to five based on data collected since the original establishment of recovery units (USFWS, 2011a). Fort Irwin is in the Western Mojave Recovery Unit.

The recovery priority number for the Mojave population of the desert tortoise has been established as 12C (USFWS, 2011a) based on:

- A moderate degree of threat
- A low potential for recovery
- Listed population below the species level
- Potential conflict with development or other forms of economic activity

The degree of threat to the Mojave population of the desert tortoise has increased since its original listing in 1990, but still is not considered to place the species at imminent risk of extinction (USFWS, 2011a).

3.1.1.2 Threats

The majority of threats to the desert tortoise or its habitat are associated with human land uses. The threats identified in the 1994 Recovery Plan formed the basis for listing the desert tortoise and continue to affect the species. However, despite clear demonstration that these threats affect individual tortoises, there are few data available to evaluate or quantify the effects of threats on desert tortoise populations (USFWS, 2011a). The threats to desert tortoise and their habitats include:

- Urbanization
- Unauthorized all-terrain vehicle (ATV) activity
- Authorized vehicular activity
- Illegal collecting
- Mortality on paved roads
- Vandalism
- Livestock grazing
- Feral burros
- Drought
- Non-native plants
- Changes to natural fire regimes
- Environmental contaminants
- Upper respiratory tract disease and other diseases

Urbanization and associated development is a major impact to the species and its habitat. Recreational use of roads and trails and large-volume, high-speed travel on major roads and highways have contributed to desert tortoise mortality, as well as habitat loss, degradation, and fragmentation. Many highways have been fenced to exclude desert tortoise, which includes US 95 south of Las Vegas; US 93 north of Las Vegas; SR 161, 163, 164, and 165; Interstate (I)-15 northeast of Las Vegas and in California; and I-10 and I-40, as well as Highways 58, 62, and 395 in California. In addition, roads and highways create an edge effect that is detrimental to desert tortoise populations (Bury, 1987; Boarman and Sazaki, 2006). Boarman and Sazaki (2006) found that desert tortoise populations are depressed next to major roadways out to a distance of at least 400 m (0.25 mi).

Drought has been implicated as a factor in reduced survival rates among desert tortoise in local areas (Longshore et al., 2003). In this 9-year study, researchers compared two "closely situated, but physiographically different, sites" in the Lake Mead National Recreation Area, Nevada. After a period when survival rates were stable, the survival rate decreased on one of the sites that experienced drought conditions in 3 out of 4 years. The authors postulate that if such local incidents occur on a regular basis, "source-sink population dynamics may be an important factor" in determining the density of desert tortoise populations.

Proliferation of invasive plants is increasing in the Mojave and Sonoran Deserts and is recognized as a significant threat to desert tortoise habitat. Many species of non-native plants from Europe and Asia have become common to abundant in some areas, particularly where disturbance has occurred and is ongoing. As non-native plant species become established, native perennial and annual plant species may decrease, diminish, or die out (D'Antonio and Vitousek, 1992). Land managers and field scientists have identified over 116 species of non-native plants in the Mojave and Colorado Deserts (Brooks and Esque, 2002).

Increased levels of atmospheric pollution and nitrogen deposition related to increased human presence and combustion of fossil fuels can cause increased levels of soil nitrogen, which in turn may result in significant changes in plant communities (Aber et al., 1989). Many of the non-native annual plant taxa in the Mojave region

evolved in more fertile Mediterranean regions and benefit from increased levels of soil nitrogen, which gives them a competitive edge over native annuals. Studies at three sites within the central, southern, and western Mojave Desert indicated that increased levels of soil nitrogen can increase the dominance of non-native annual plants and promote the invasion of new species in desert regions. Furthermore, increased dominance by non-native annuals may decrease the diversity of native annual plants, and increased biomass of non-native annual grasses may increase fire frequency (Brooks, 2003).

Nutritional intake affects growth rates in juvenile desert tortoises (Medica et al., 1975) and female reproductive output (Turner et al., 1986, 1987; Henen, 1992). Invasion of non-native plants can affect the quality and quantity of plant foods available to desert tortoise, and thereby affect nutritional intake. Desert tortoise typically are quite selective in their choices of foods (Burge, 1977; Nagy and Medica, 1986; Turner et al., 1987; Avery, 1992; Henen, 1992; Jennings, 1992, 1993; Esque, 1992, 1994), and in some areas the preferences are clearly for native plants over the weedy non-native species.

As native plants are displaced by non-native invasive species in some areas of the Mojave Desert, non-native plants can be a necessary food source for some desert tortoises. However, non-native plants may not be as nutritious as native plants. Recent studies have shown that the availability of calcium and phosphorus is higher in forbs than in grasses and that desert tortoise lose phosphorus when feeding on grasses but gain phosphorus when eating forbs (Hazard et al., 2002). A comparative study on the nutritional qualities of native vs. non-native grasses and forbs commonly consumed by desert tortoises (*Achnatherum hymenoides* [Indian ricegrass] vs. *Schismus barbatus* [Mediterranean grass]; *Malacothrix* spp. [desert dandelion] vs. *Erodium cicutarium*), found that the nutritional value of the two grasses was similar, but both grasses had much lower nutritional value than the forbs (Nagy et al. 1998). This suggests that the proliferation of non-native grasses such as *Schismus* to the exclusion of native forbs and other plants places desert tortoises at a nutritional disadvantage (D'Antonio and Vitousek, 1992). Furthermore, if desert tortoise consume just enough food to satisfy their energy needs (as commonly noted in other vertebrate groups), then the native forbs provide significantly more nitrogen and water than the non-native forbs (Nagy et al., 1998).

Changes in the abundance and distribution of native plants also may affect desert tortoise in more subtle ways. In the Mojave Desert, many food plants are high in potassium (Minnich, 1979), which is difficult for desert tortoise to excrete due to the lack of salt glands that occur in other reptilian herbivores such as chuckwalla (*Sauromalus obesus*) and desert iguana (*Dipsosaurus dorsalis*) (Minnich, 1970; Nagy, 1972). Reptiles are unable to produce osmotically concentrated urine, which further complicates the ability of the desert tortoise to expel excess potassium (Oftedal and Allen, 1996). Oftedal (2002) suggested that desert tortoise may be vulnerable to upper respiratory tract disease or other diseases due to their need to obtain sufficient water and nitrogen from food plants to counteract the negative effects of dietary potassium. Only high quality food plants (as expressed by the potassium excretion potential, or PEP, index) allow substantial storage of protein (nitrogen) that is used for growth and reproduction, or to sustain the animals during drought. Non-native annual grasses have lower PEP indices than most native forbs (Oftedal, 2002; Oftedal et al., 2002). Foraging studies have demonstrated that juvenile Mojave Desert tortoises are highly selective while foraging, selecting both the plant species and plant parts that have the highest PEP value. Impacts to vegetation (such as livestock grazing, invasion of non-native plants, and soil disturbance) that reduce the abundance and distribution of high-PEP plants may result in additional challenges for foraging desert tortoise (Oftedal et al., 2002).

In addition, predation by common ravens and coyotes is considered a threat that may be increasing in severity due to the expansion of human activities into more remote locations throughout the desert or prey shifting because of prolonged drought and a lack of prey species (e.g., lagomorphs). Common raven populations in some areas of the adjacent Mojave Desert have increased 1,500 percent from 1968 to 1988 in response to expanding human use of the desert (Boarman, 2002). Since ravens were scarce in the desert prior to 1940, the existing level of raven predation on juvenile desert tortoises is considered an unnatural occurrence (BLM, 1990). In addition to ravens, domestic and feral dogs have emerged as significant predators of desert tortoises in areas adjacent to residential development (USFWS, 2012b).

3.1.1.3 Recovery Criteria

The *Revised Recovery Plan for the Mojave Population of the Desert Tortoise (Gopherus agassizii)* identifies the following recovery goals and objectives (USFWS, 2011a):

- Recovery Objective 1 (Demography). Maintain self-sustaining populations of desert tortoise within each recovery unit into the future.
  Recovery Criterion 1. Rates of population change for desert tortoise are increasing over at least 25 years (a single tortoise generation), as measured
  - by extensive, range-wide monitoring across tortoise conservation areas within each recovery unit, and
  - by direct monitoring and estimation of vital rates (recruitment, survival) from demographic study areas within each recovery unit.
- Recovery Objective 2 (Distribution). Maintain well-distributed populations of desert tortoise throughout each recovery unit.
  Recovery Criterion 2. Distribution of desert tortoise throughout each tortoise conservation area is increasing over at least 25 years.
- Recovery Objective 3 (Habitat). Ensure that habitat within each recovery unit is protected and managed to support long-term viability of desert tortoise populations.
  Recovery Criterion 3. The quantity of desert tortoise habitat within each desert tortoise conservation area is maintained with no net loss until tortoise population viability is ensured.
  The condition of desert tortoise habitat should also be demonstrably improving.

3.1.2 Lane Mountain Milk-vetch

3.1.2.1 Listing History

Lane Mountain milk-vetch was federally listed as endangered on October 6, 1998 (USFWS, 1998 [63 FR 53596]). The species was first recommended for endangered status in January 1975. On June 4, 2012, USFWS issued a 90-day petition finding in the FR that reclassification of the Lane Mountain milk-vetch from endangered to threatened may be warranted and initiated a status review for the species (USFWS, 2012c).

The discovery and accumulation of knowledge concerning the distribution and abundance of Lane Mountain milk-vetch are discussed by Charis (2002). Intensive plot and transect surveys by Prigge et al. (2000, 2001) and Charis (2002) covered all areas previously known or suspected to support the species, and resulted in a determination of its distribution (Charis, 2002). Lane Mountain milk-vetch is known to occur in four relatively discrete locations (Prigge et al., 2000, 2001; Charis, 2002). For identification purposes, the populations have been named Coolgardie Mesa, Paradise Valley, Brinkman Wash–Montana Mine, and NASA Goldstone. However, the populations identified for Brinkman Wash-Montanan Mine and NASA Goldstone have been determined to be geographically contiguous and are now consolidated as the Goldstone-Brinkman Unit (USFWS, 2011b). The Coolgardie Mesa population and a small portion of the Paradise Valley population are outside of Fort Irwin. A portion of the NASA Goldstone population is on Fort Irwin land permitted for use to the National Aeronautics and Space Administration (NASA). The rest of the Paradise Valley population and the Goldstone-Brinkman Unit are on Fort Irwin but are outside the action area.

The Coolgardie Mesa population is the largest known population, containing an estimated 8,000 to 20,000 individual plants and nearly 46 percent of the total known habitat.

3.1.2.2 Threats

Threats to the Lane Mountain milk-vetch identified by the USFWS include habitat destruction from dry wash gold mining, rock and mineral collecting, and ATV recreation and threats due to military activity (USFWS, 1998). An

increase of non-native grasses spreading from road grading and other ground-disturbing activities increases the potential for fire frequency and species competition, and may have long-term deleterious effects on Lane Mountain milk-vetch. Small populations are vulnerable to extirpation simply by chance due to fluctuating environmental conditions and demographic stochasticity. A small portion of the distribution of the species near Brinkman Wash on Fort Irwin is subject to habitat disturbance associated with military training. However, the area is infrequently used and most of the area has been designated as a "no dig zone" and off-limits for mechanized training since 1991.

3.1.2.3 Recovery Criteria

A recovery plan has not been developed for this species and no recovery criteria have been established (USFWS, 2008).

3.2 Status of Designated Critical Habitat

3.2.1 Desert Tortoise

The Mojave population of the desert tortoise was listed as threatened on April 2, 1990, with a recovery plan published in June 1994. The recovery plan included a supplement that identified proposed Desert Wildlife Management Area (DWMAs). Critical habitat was designated in 1994 (58 FR 45748), under provisions of the ESA (16 U.S.C. 1531, *et seq.*), based largely on the DWMAs identified in the 1994 Recovery Plan and encompassed more than 6.4 million ac. Critical habitat was designated in all four states supporting the species. Designated critical habitat for the desert tortoise occurs on the southern and southwestern portions of Fort Irwin. The boundary of the Superior-Cronese critical habitat unit is less than 5 mi west of the action area, but the critical habitat does not extend into the action area (Figure 1-1).

3.2.2 Lane Mountain Milk-vetch

On April 1, 2010, the USFWS proposed revised designation of critical habitat for Lane Mountain milk-vetch (79 FR 16404-16421) under provisions of the ESA (16 U.S.C. 1531, *et seq.*). Following an extensive review of information and public comments, the USFWS formally designated critical habitat for the species in a final ruling published on May 19, 2011 (76 FR 29108-29129). In total, approximately 14,069 ac of land in 2 units located in the Mojave Desert in San Bernardino County, California, fall within the boundaries of the revised critical habitat designation. The action area does not include any designated critical habitat for the Lane Mountain milk-vetch.

Fort Irwin National Training Center Solar Facility Project
Natural Resources Report
Fort Irwin, California

4 Environmental Baseline

This section is limited to a discussion of the desert tortoise. Because Lane Mountain milk-vetch does not occur in the action area and there is no designated critical habitat for it within the action area. Therefore, Lane Mountain milk-vetch is not further discussed as the proposed project would have no potential to affect this species.

Per 50 CFR 402.02, the environmental baseline includes the past and present impacts of all Federal, State, or private actions and other human activities in the action area, the anticipated impacts of all proposed Federal projects in the action area that have already undergone formal or early Section 7 consultation, and the impact of State or private actions which are contemporaneous with the consultation in process. For the action area, the past impacts to the action area would include military training activities, unauthorized off-road vehicle use, the construction and maintenance of Fort Irwin Road, development of the ORV use area, and the construction and maintenance of the electric substation and associated electrical transmission infrastructure. Military training is no longer conducted in this area and no additional State or private actions are known or planned that would be contemporaneous with this consultation.

4.1 Existing Baseline Conditions

The action area is the 380 ac of desert tortoise habitat adjacent to Fort Irwin Road, as depicted on Figure 3-1. The habitat within the action area is Mojave creosote bush scrub, and is dominated by a sub-association of this vegetation type: the creosote *(Larrea tridentata)* –burrobush *(Ambrosia dumosa)* association. Creosote bush covers extensive portions of the action area in nearly pure stands, and occurs in close association with burrobush in other areas.

Optimal habitat for the desert tortoise has been characterized as creosote bush scrub in which annual precipitation ranges from 2 to 8 inches, where the diversity of perennial plants is relatively high and production of ephemerals also is high (USFWS, 2011a). Soils must be friable enough for digging burrows, but firm enough so that burrows do not collapse. Desert tortoise occur from below sea level to an elevation of 7,300 feet, but the most favorable habitat occurs at elevations of approximately 1,000 to 3,000 feet (USFWS, 2011a).

Desert tortoise most commonly occur within desert scrub vegetation, primarily in creosote bush scrub. They also occur in succulent scrub, cheesebush scrub, blackbrush scrub, hopsage scrub, shadscale scrub, microphyll woodland, Mojave saltbush-allscale scrub, and scrub-steppe vegetation types of the desert and semidesert grassland complex (USFWS, 1994). Throughout most of the Mojave region, desert tortoise occur most commonly on gently sloping terrain with soils ranging from sandy to gravelly, and in areas with scattered shrubs where there is abundant inter-shrub space for growth of herbaceous plants (Gardner and Brodie, 2000).

Watershed or Other Relevant Habitat Unit

The action area is within the Coyote watershed basin and within the Western Mojave Recovery Unit for the desert tortoise, as defined by USFWS (2011a). There are no perennial watercourses within the region. Washes descending from mountains and other elevated landforms provide channels for ephemeral and intermittent flows of surface runoff into topographical depressions or playas where ephemeral lakes form. Water accumulates in these areas during times of greater-than-average precipitation, which occur on average at least once every 10 years.

4.1.1 Shelter

A diversity of plant species within a desert tortoise habitat plays a key role in providing shelter sites for protection from predators and environmental extreme. Desert tortoise are most active during April/ May and September/

October. Desert tortoise may be active during periods of mild or rainy weather in summer and winter. During inactive periods, tortoises rest in subterranean burrows or caliche caves, and spend approximately 98 percent of the time in these shelter sites (Nagy and Medica, 1986). During active periods, they usually spend nights and the hotter part of the day in their burrow. Tortoises also may rest under shrubs or in shallow burrows (pallets) and use an average of 7 to 12 burrows at any given time (Bulova, 1994; TRW Environmental Safety Systems Inc.,1997).

Walde et al. (2003) observed that desert tortoise retreat into burrows when air temperature reach approximately 91.0° F and ground temperatures reach approximately 94.6 °F; 95 percent of observations of desert tortoises above ground occurred at air temperature less than 91 °F. The body temperature at which desert tortoise become incapacitated ranges from 101.5 °F to 113.2 °F (Naegle, 1976; Zimmerman et al., 1994).

The action area is within the central Mojave Desert region of the Desert Floristic Province (Hickman, 1993) and has only one vegetative community type, Mojave creosote bush scrub, and is dominated by a sub-association of this vegetation type: the creosote *(Larrea tridentata)* –burrobush *(Ambrosia dumosa)* association. Creosote bush covers extensive portions of the action area in nearly pure stands, and occurs in close association with burrobush in other areas. Other plant species observed in the action area include Mormon tea (*Ephedra nevadensis*) and brittlebush (*Encelia farinose*). All native plants observed within the action area are identified in the survey report, which is provided as Appendix A. Much of the action area was historically disturbed by military training activities and there are several shallow bomb craters. There was evidence of some ATV use within the action area.

Soils throughout the action area are primarily derived from limestone and dolomite parent material and are characterized by well-drained sandy textures with a relatively high cover of rock fragments on the surface. The soil units present in the action area are the Kimberlina series and the Calvista series, which are suitable for excavation of desert tortoise burrows.

The action area includes shrub vegetation that can provide shelter from potential predators and heat (USFWS, 2012d) and soils suitable for excavation of burrows to provide shelter during resting and dormant periods.

4.1.2 Feeding

Tortoise activity patterns are primarily controlled by ambient temperature and precipitation (Nagy and Medica, 1986; Zimmerman et al., 1994). Desert tortoise are active for approximately 6 weeks to 5 months of the year, depending on annual variations of temperature and rainfall. Desert habitats are characterized by prolonged periods of barely measurable rainfall. In much of the Mojave Desert, droughts of 8 months or more occur frequently. During such times, the desert is virtually devoid of food for tortoises except for cacti and dried grasses (Oftedal, 2002). Most precipitation occurs in winter in the West Mojave Desert, resulting in abundant annual spring vegetation that dries by late May or June. Desert tortoises in the West Mojave Desert are primarily active in May and June, with a secondary activity period from September through October.

In drought years, the ability of desert tortoise to drink while surface water is available following rains may be crucial for tortoise survival. During drought, desert tortoise forage over larger areas, increasing the likelihood of encounters with sources of injury or mortality, including humans and predators.

Although desert tortoise eat non-native plants, they generally prefer native forbs when available (Jennings, 1993; Avery, 1998). The vegetation in the action area, described in Section 4.1.1, provides an assemblage of native species that is suitable as forage for desert tortoise during periods of ephemeral plant growth.

4.1.3 Reproduction

Desert tortoise may live 50 or more years in the wild. Reproduction begins between ages 12-20, with clutch sizes of 1-14 eggs. In years with low rainfall, females may lay few to no eggs. Females can store sperm for 5 years or longer, meaning they can reproduce for several years after mating. Nests are built and eggs are laid in late spring or early summer. The hatchlings appear in 90 to 120 days. There is no maternal care of young, so hatchlings must survive on their own (USFWS, 2012d). An unhatched egg was found in the action area during the 2012 survey (CH2M HILL, 2012, Appendix A).

4.1.4 Habitat Connectivity and Migration

Tortoise activities are concentrated in overlapping core areas, known as home ranges. The size of desert tortoise home ranges varies with respect to location and year. Individual desert tortoise do not migrate in the true sense of the term. However, desert tortoise do move about within their home ranges and the ability to move among burrows, foraging areas, water sources, and mineral deposits to meet life history requirements is crucial to survival of individual desert tortoise. As noted in the discussion of threats in Section 3, human activity can create barriers to movement and affect the ability of a tortoise to meet all these life history needs.

Male desert tortoise actively defend their home ranges against other males. Female desert tortoise typically do not defend territories. In the West Mojave Desert, the estimated mean home range is 111 ac for male desert tortoise and 40 ac for female desert tortoise (Harless et al., 2009). Over an average lifetime, desert tortoise may require more than 960 ac of habitat and a tortoise may make forays of more than 7 mi (Berry, 1986).

The Mojave desert tortoise exhibits broad patterns of migration interrupted by major topographic barriers, based on analysis of gene flow among subunits (USFWS, 2011a). However, migration among populations is not a rapid process and is not expected to occur on the order of decades (USFWS, 2011a).

5 Natural History and Species Occurrence

Two federally listed species, desert tortoise and Lane Mountain milk-vetch, were determined to have the potential to occur within the action area. Desert tortoise were found within the action area during the field surveys. Lane Mountain milk-vetch was not found during field surveys (Appendix A) and is not expected to occur within the action area. Because no potential to impact Lane Mountain milk-vetch or its habitat exists, this species is not further discussed.

5.1 Site Specific Biological Requirements and Project Context

The desert tortoise is well studied at Fort Irwin. Numerous surveys have been conducted over the years to document the distribution and estimated size of tortoise populations throughout the installation. The desert tortoise is known to occur throughout Fort Irwin in low to moderate numbers, with the highest concentration of tortoises in the Superior Dry Lake portion of Fort Irwin, which does not include the action area.

Elevations in the action area range from approximately 2,600 feet above mean sea level (amsl) on the southeastern corner to approximately 3,200 feet amsl on the northwestern edge, which is within the elevation range where desert tortoise occur. As discussed in Section 4, the vegetation and soils in the action area provide suitable foraging and burrow habitat for the species.

The action area, which extends from the main gate access road east toward Tiefort Mountain, was evaluated for the presence of desert tortoise and Lane Mountain milk-vetch. CH2M HILL biologists conducted surveys to identify and map threatened and endangered species habitat within the proposed solar facility site and transmission line corridor from March 26, 2012, through March 29, 2012. Protocol presence/absence surveys (USFWS, 2010) were conducted for desert tortoise within the action area by walking transects at 10-m spacing throughout the action area and three additional 10-m belt transects at 200-m intervals parallel to the northern border of the transmission line corridor (200 m, 400 m, and 600 m from the perimeter), to account for an adjacent zone of influence in accordance with USFWS protocol for a linear site. The survey area is shown in Figure 3-1 and the results of the survey (CH2M HILL, 2012) are provided as Appendix A.

Three desert tortoise were observed during the field survey, two of which were within burrows. Four additional desert tortoise burrows that appeared to be active were observed along with three apparently inactive burrows. One unhatched egg from 2011 was observed. Five relatively intact desert tortoise carcasses were observed and eight other occurrences of shell-skeletal remains were observed (Figure 3-1, Appendix A).

5.2 Site Specific Critical Habitat and Project Context

The project is located within the Western Mojave Recovery Unit (USFWS, 2011a) but is not within designated Desert Tortoise Critical Habitat. The boundary for the Superior-Cronese critical habitat unit is less than 5 mi west of the action area.

5.3 Site Specific Limiting Factors for Recovery

Based on the site survey results, desert tortoise densities in the action area are low (CH2M HILL, 2012) and the tortoise population in the action area represents a very low percentage of the entire Mojave population. Population trend analysis indicates that the Superior-Cronese designated critical habitat unit area to the south of the action area along Fort Irwin Road had a higher than average occurrence of live desert tortoise(Tracy et al., 2004). Historic densities of desert tortoise within the action area and on Fort Irwin prior to military maneuvers

are unknown, as no population studies were conducted. At present, Mojave desert tortoise populations are considered to be depressed and well below the listing level for the species due to a prolonged drought cycle with extremely elevated mortality and decreased reproduction. Low desert tortoise densities observed within the action area (CH2M HILL, 2012), relative to other parts of Fort Irwin and to nearby designated critical habitat, suggest that the action area does not represent tortoise habitat that is crucial for recovery.

6 Analysis of Effect of the Action

This section discusses potential project effects and cumulative effects for the Desert Tortoise. Project effects include direct effects ("take" associated with construction and operation activities and habitat loss, as described in Sections 4 and 5) and indirect effects (for example, from habitat degradation as a result of runoff from increased impervious surfaces).

Permanent effects will be limited to the action area and the immediately surrounding area. Project activities will result in permanent effects to desert tortoise habitat as a result of the following activities: grading, paving, and excavating. A total of approximately 380 ac of permanent effects to desert tortoise habitat would occur during construction. Operation and maintenance of the solar facility and the associated electrical transmission corridor would not further affect habitat. Implementation of the avoidance and minimization measures listed in Section 7 would minimize potential effects to desert tortoise and associated habitat from construction, operation, and maintenance of the solar facility and its associated infrastructure.

While there are potential adverse indirect effects associated with the project, these effects would be reduced or avoided by implementing avoidance and minimization measures. General measures and species-specific measures that Fort Irwin will implement during construction and operation to avoid and minimize project-related effects are described in Section 7.

6.1 Direct Effects

Project actions could result in direct mortality, injury, or harassment of individuals as a result of encounters with vehicles or heavy equipment in the action area. The proposed action contains measures to minimize or eliminate the effects from vehicles straying from designated access or designated areas into adjacent habitat. In addition, direct effects may include individual tortoises being crushed or entombed in their burrows, nest destruction, disruption of tortoise behavior during construction or operation of facilities, and disturbance by noise or vibrations from the heavy equipment.

6.1.1 Direct Effects from Construction

Increased human activity and vehicle travel would occur from the construction and improvement of access roads, which could disturb, injure, or kill individual tortoises. Installation of the exclusion fencing could result in direct effects such as mortality, injury, or harassment of desert tortoise due to equipment operation, installation activities, destruction of tortoise burrows, and tortoise relocation. The Authorized Biologist will oversee installation of the temporary exclusion fencing prior to construction to minimize the potential for impacts to desert tortoise.

Clearance surveys conducted in advance of construction will result in harassment of any desert tortoise within the action area from the presence of the surveyors. Exclusion fencing will be placed around the action area and any desert tortoise within the action area will be translocated outside the exclusion fencing. The exclusion fencing would preclude desert tortoises from re-entering the work areas. This would result in fragmentation of habitat and individual home ranges.

Capturing, handling, and translocating desert tortoises from the site will result in capture and harassment. However, USFWS has stated that it does not expect that the capture and handling of desert tortoises (e.g., to remove them from harm's way), when conducted by Authorized Biologists, is likely to result in injury or mortality (USFWS BO of April 27, 2012).

As noted in the discussion of threats in Section 3, there is an edge effect on desert tortoise populations near major highways that extends out to a distance of at least 400 m (0.25 mi) (Bury, 1987; Boarman and Sasaki 2006).

Desert tortoise densities in the action area appear depressed (CH2M HILL, 2012) and an edge effect along Fort Irwin Road may be contributing to the depressed densities. Because the fence construction would occur within an area that is largely disturbed and where desert tortoise abundance is documented to be low (CH2M HILL, 2012), this activity is expected to affect few, if any, desert tortoises or nests. Once the fence is in place and any tortoise removed from the construction area, no further direct effects to desert tortoise from construction activities would be expected.

Blythe et al. (2003) found that translocated Sonoran Desert tortoises translocated less than 0.5 mi returned to their home ranges within a few days. Tortoises translocated outside their home ranges would likely attempt to return to the area from which they were moved, which would increase the potential for exposure to adverse effects associated with project construction. However, because the action area would be fenced to exclude desert tortoise re-entry and other minimization measures would be adhered to, the probability of direct effects to individuals would be relatively low.

The construction and operation of the proposed solar facility would eliminate 380 ac of habitat from the Western Mojave Recovery Unit. This loss of habitat would represent less than 0.01 percent of the habitat in the Western Mojave Habitat Unit and would not result in an appreciable change in the abundance and distribution of desert tortoise within the unit.

No designated critical habitat for the desert tortoise occurs in the action area. The nearest designated critical habitat for this species is 5 mi away (the northern and eastern part of the Superior-Cronese critical habitat unit). There would be no direct effects to critical habitat for the desert tortoise from construction activities.

6.1.2 Direct Effects from Operation

Desert tortoise have been documented nesting in commercial scale wind energy facilities in numbers and with hatchling success comparable to nearby undisturbed habitat (Ennen et al., 2012). Because the species has been shown to coexist with similar energy projects, no direct effects from operation of the solar facility would be expected. The use of exclusion fencing around the facility would prevent desert tortoise exposure to vehicular traffic that would deliver water and materials for maintenance.

Maintenance activities on the electric transmission corridor could result in interaction with desert tortoise. The transmission corridor would not be fenced and desert tortoise may use the habitat in this corridor and be present during maintenance activities. Because the corridor will be adjacent to Fort Irwin Road, the edge effect from the road may reduce this possibility. Prior to any maintenance activity involving off-road use of vehicles or equipment, the area where vehicles and equipment would be operated would be subjected to a clearance survey and temporary exclusion fencing would be placed around the work areas to prevent desert tortoise entry during maintenance activities. The fencing would be removed when maintenance is complete.

There would be no direct effects to critical habitat for the desert tortoise from operations and maintenance activities.

6.2 Indirect Effects

Indirect effects are those that are caused by, or result from, the proposed action and are later in time, but reasonably certain to occur. In contrast to direct effects, indirect effects are more subtle, and may affect individuals, populations, and habitat quality over an extended period of time, long after construction activities have been completed. Indirect effects are of particular concern for long-lived species such as the desert tortoise because project-related effects may not become evident in individuals or populations until years later. Indirect effects may include increased predation by common ravens, loss or fragmentation of habitat linkages from creation of permanent barriers to movement that disrupt population and genetic connectivity, degradation of habitat and the diet of desert tortoises from the spread of non-native plant species or increased erosion,

degradation of habitat to other desert tortoise populations whose home ranges may overlap the proposed project area, and noise and lighting from human activities.

6.2.1 Indirect Effects from Construction

Should a precipitation event occur during construction, there could be indirect effects to desert tortoise habitat from stormwater runoff across disturbed soils and associated erosion and sedimentation. Scour could remove vegetation and sedimentation could fill burrows or bury vegetation and nests. The Army would require the contractor to implement appropriate best management practices (BMPs) before any initial disturbance and maintain those BMPs throughout construction. Erosion control measures such as application of compost blankets, mulch, riprap, or geotextiles to stabilize slopes could be implemented to protect exposed soil and minimize erosion. BMPs such as directional grading, check dams, slope diversions, and temporary diversion dikes could be implemented for runoff control. Sediment control measures that could be implemented to reduce sediment leaving the site include compost filter berms and socks; fiber rolls or berms; sediment basins, rock dams, filters, chambers, or traps; silt fences; and hay bales. Implementation and maintenance of appropriate BMPs during construction would make it unlikely that indirect effects to desert tortoise habitat would occur from stormwater runoff and associated erosion and sedimentation.

Invasion of non-native plants can affect the quality and quantity of plant foods available to desert tortoises, and thereby affect nutritional intake. Nutritional intake affects growth rates in juvenile desert tortoises (Hazard et al., 2010) and female reproductive output (Henen, 1992). The dominant annual species in the action area found during surveys was Mediterranean grass (*Schismus arabicus*). The presence of this species as a dominant in the action area indicates that forage quality in the action area has already been adversely impacted by invasive exotic species. Soils disturbance during construction can make the area more susceptible to invasion by other non-native species and further degrade the habitat.

Based on the ability to adapt to noise disturbance, noise attenuation as distance from the project increases, and the fact that desert tortoises do not rely on auditory cues for their survival, it is likely that no desert tortoises would be injured or killed as a result of project-related noise. Minimization measures that are part of the proposed action would further protect the species.

Because Fort Irwin Road borders the action area, the erection of permanent exclusion fencing would not be expected to be a major impediment to movement of desert tortoise within their home ranges. Because the desert tortoise population in the action area is depressed, it is unlikely that desert tortoise are routinely traveling across the action area to the opposite side of Fort Irwin Road. Any effects as a result of barriers to desert tortoise movement would be minimal.

No indirect effects to desert tortoise would be expected from maintenance of the transmission corridor. Any maintenance activity would be of short duration and there would be no offsite effects and no effects that would persist.

The project would not result in fragmentation of the existing critical habitat for the desert tortoise, because the project is not located within critical habitat for the species. There would be no indirect effects to critical habitat for the desert tortoise from construction activities.

6.2.2 Indirect Effects from Operation

The solar facility will have a greater amount of impervious area than is present in the action area, which would result in increased stormwater runoff and associated erosion and sedimentation if not controlled. The Army would require implementation of post-construction BMPs to maintain pre-development runoff flow volumes and rates and prevent any offsite effects from stormwater runoff during operation of the solar facility. Post-construction BMPs would include detention ponds and flow diversions, which would maintain pre-development runoff flows for 10-year floods and attenuate larger storm events. Any indirect effects from stormwater runoff and associated erosion and sedimentation would be minimal.

The solar facility and transmission corridor could provide additional temporary and permanent nesting, perching, and roosting sites for the common raven. The potentially increased common raven population within the area could cause the indirect effect of increased predation to juvenile desert tortoises.

Maintenance activities would be conducted inside the fenced solar facility and would not result in offsite effects. Water trucked in for washing the solar panels would be contained within the post-construction stormwater BMPs discussed above. No indirect effects to desert tortoise from routine maintenance of the solar facility during operations would be expected.

The generation of electricity during operation of the solar facility would have no offsite effects and would not result in indirect effects to desert tortoise.

There would be no indirect effects to critical habitat for the desert tortoise from operations and maintenance activities.

6.3 Effect of the Proposed Action on Tribal Resources or Interests

The Army has evaluated the potential for effects to Native American interests and resources and determined that the proposed action would result in no affects to tribal resources or interests.

6.4 Estimating Take

The fundamental duty of a federal lead agency under Section 7 of the ESA is to ensure that federal actions do not jeopardize the continued existence of listed species. As noted on page 4-50 of the ESA Section 7 Consultation Handbook (USFWS and National Marine Fisheries Service, 1998): *Section 7 requires the minimization of the level of take. It is not appropriate to require mitigation for the impacts of incidental take.*

As required by the ESA, Fort Irwin will implement reasonable and prudent measures to minimize and avoid take of listed species. The Fort Irwin project would not jeopardize the continued existence of desert tortoise.

While the proposed project has the potential to affect desert tortoise, the avoidance and minimization measures, as described in Section 7, would minimize the potential adverse effects.

The take associated with construction of the solar facility and transmission corridor would likely be limited to harassment of desert tortoise during surveys and relocation and creation of barriers to movement. While mortality is possible, no mortality would be expected from these actions.

Use of the exclusion fencing would prevent direct mortality during construction.

6.5 Cumulative Effects

Cumulative effects are defined in 50 CFR §402.02 as "those effects of future State or private activities, not involving Federal activities that are reasonably certain to occur within the action area of the Federal action subject to consultation." The Fort Irwin project would be built and operated entirely within Fort Irwin. No future State or private activities are known for the vicinity of the action area. The closest activities are military training activities and maintenance of Fort Irwin Road, but these represent continued baseline activities and would not change conditions in the action area.

The direct and indirect effects of the project would be minimal, and appropriate avoidance and minimization measures would be implemented. Therefore, the project would not be expected to result in adverse cumulative effects to desert tortoise.

7 Avoidance and Minimization Measures

As required under the ESA, Fort Irwin will implement reasonable and prudent measures to minimize and avoid potential take of desert tortoise.

7.1 Standard Specifications

The following avoidance and minimization measures will be incorporated into the project:

- **Erosion and Sediment Control Plan**. Fort Irwin will prepare and implement an erosion control and restoration plan to control short- and long-term erosion and sedimentation effects, and to restore soils and vegetation in areas affected by construction activities. The plan will include all necessary requirements regarding erosion control, and will include BMPs for erosion and sediment control as required. Only appropriate native plant material will be used for erosion control and restoration. Erosion control will be placed on all disturbed slopes and material disposal sites.
- **SWPPP**. Fort Irwin will submit to the Regional Water Quality Control Board (RWQCB) a notice of intent to discharge stormwater before construction and/or operation activities begin. Also, Fort Irwin will develop and implement a SWPPP, as required by the conditions of a National Pollutant Discharge Elimination System (NPDES) permit. Fort Irwin will prepare a SWPPP that identifies BMPs for discharges and for groundwater disposal from dewatering operations associated with road construction. The SWPPP will identify how and where these discharges would be disposed of during construction and operations. The SWPPP will include provisions for the following:
  - The area of ground disturbance will be minimized. No ground disturbance will be allowed outside the limits defined in permits. Preservation of existing vegetation will be provided to the maximum extent practical. Required BMPs will be in place during construction of the project to minimize effects to desert tortoise habitat. The limits of the construction areas will be marked with high visibility fencing to clearly identify the construction area relative to sensitive areas. These areas also will be surrounded by exclusion fencing to prevent desert tortoise entry.
  - Temporary erosion control devices will be an integral part of construction. Sedimentation fences will be used to contain polluted or turbid runoff from the work site. Other methods of temporary erosion control, including but not limited to hay bale check dams, will be employed to protect areas susceptible to damage from runoff. Erosion control devices will be installed concurrently with construction earthwork.
  - Sediment control will be maintained at construction site entrances/exits.
  - Spill control BMPs will be implemented any time chemicals and/or hazardous substances are stored or used on the project. Employees of contractors will be educated in proper material handling, spill prevention, and clean-up. Clean-up materials will be onsite and located near material storage and use areas.
  - Erosion control devices will be monitored on a regular basis and augmented as necessary. In the event of pending storms, and in compliance with the SWPPP, erosion control devices will be inspected to ensure that they are in place and are functional. Monitoring and maintenance of erosion control devices and adjacent disturbed areas will continue during and immediately after storm events.
- **Dust Control.** If dust control measures are needed, standard dust control BMPs will be used. Any material stockpiles will be watered, sprayed with tackifier, or covered, to minimize dust production and wind erosion.
- **General Housekeeping.** To prevent attraction of predators, all food-related trash items such as wrappers, cans, bottles, and food scraps will be disposed of in closed containers and removed at least once every 3 days

and all containers that may hold water following a precipitation event or application of water for dust control will be stored in closed areas or inverted to prevent creation of a water attractant.

- **Pets.** To prevent harassment, injury, or mortality of a desert tortoise or destruction of their refuge areas, no pets will be permitted in the action area.
- **Invasive Plant Species**. When practicable, invasive plants in the action area will be removed. Fort Irwin will comply with Executive Order 13112, to reduce the spread of invasive non-native plant species and minimize the potential decrease of palatable vegetation for wildlife species. This order is intended to prevent the introduction of invasive species and provide for their control in order to minimize the economic, ecological, and human health impacts.

7.2 Special Provisions Specifications

- **Permits.** All appropriate State and Federal permits for handling desert tortoises or their parts, must be acquired by the Authorized Biologist(s) or other personnel before project initiation and prior to handling any desert tortoise or their parts, or conducting any activity requiring a permit.
- **Clearance Surveys.** Within 2 weeks of the onset of construction, 100 percent coverage ground surveys of the action area, including all associated linear facilities (transmission corridor, access roads, etc.) will be conducted for desert tortoise, signs of desert tortoise use, or desert tortoise burrows. If no tortoises or active burrows are identified, construction will proceed without interruption. The Authorized Biologist (see Biological Monitoring item below) will direct clearance surveys for desert tortoise within the action area. This will include the clearance of any tortoise burrows within this corridor to ensure that any tortoise present are moved out of harm's way prior to grubbing consistent with the following details. There is ample similar habitat adjacent to the action area and throughout Fort Irwin available for potential relocation of desert tortoise. Desert tortoise could be relocated to other areas with fewer disturbances, including established conservation areas on Fort Irwin, and away from ATV trails. Once the action area is deemed free of desert tortoise and after exclusion fencing (see below) is in place, in accordance with USFWS clearance survey protocols, heavy equipment would be allowed to enter the site to perform earthwork such as clearing, grubbing, leveling, and trenching.
- **Relocation.** Tortoise handling, burrow construction, egg handling, and other procedures will follow those described in the Guidelines for Handling Desert Tortoise during Construction Projects (Desert Tortoise Council, 1994). Unavoidable burrows inhabited by tortoises will be excavated by the Authorized Biologist(s) using hand tools. To prevent re-entry by a tortoise, all burrows within the action area that do not contain tortoises will be collapsed.
- **Exclusion Fencing**. Fort Irwin will instruct the contractor to install temporary desert tortoise exclusion fencing around the entire solar project construction area, including the transmission corridor, prior to start of construction. This fencing will be installed under direction of an Authorized Biologist and would be done prior to the site clearance survey to prevent desert tortoise from reentering the area following the clearance survey. Construction equipment entrances will also be gated to further prevent tortoises from entering the construction site. The fence will be installed with an Authorized Biologist present. Fence design will be a minimum of 18 inches tall and consist of 1-inch horizontal by 2-inch vertical mesh (hardware cloth or plastic) and be installed flush with the ground. Fencing will be inspected daily during construction and weekly during operation. Any damage to the fencing will be repaired. Zero clearance will be maintained between the bottom of the fence and the ground to ensure that any bent portions are properly covered. Temporary exclusion fencing would be removed following completion of construction.
  Upon completion of construction, the solar facility will be surrounded with permanent exclusion fencing to prevent tortoise re-entry into this area. Fence design will be a minimum of 18 inches tall and consist of 1-inch horizontal by 2-inch vertical mesh (hardware cloth or plastic) and will be installed 24 to 36 inches below the ground surface. The transmission corridor would not have permanent exclusion fencing.

- **Worker Training.** The Authorized Biologist(s) will conduct a training session for all construction workers before work is started on the project. The Authorized biologist(s) or designated desert tortoise monitor(s) will inform field management and construction personnel of the need to avoid and protect resources by preparing and implementing a worker environmental awareness program. The program will provide workers with information on their responsibilities with regard to the desert tortoise and other sensitive species. Construction personnel will be educated on the types of sensitive resources located in the action area and the measures required to avoid effects on these resources. All construction personnel will attend an environmental training program before groundbreaking activities. Materials covered in the training program will include environmental rules and regulations for the project, requirements for limiting activities to the construction right-of-way, and avoidance and minimization measures designed to protect demarcated sensitive resource areas. Training will educate construction supervisors and managers on the need for pre-construction surveys; construction drawing format and interpretation; staking methods to protect resources; the construction process; roles and responsibilities; project management structure and contacts; environmental commitments; implementation of BMPs; and emergency procedures.

- **Biological Monitoring.** Authorized Biologist(s) will be appointed to oversee all biological work. The Authorized Biologist will perform the following during any site (or related facilities) mobilization, ground disturbance, grading, construction, operation, and closure activities. The Authorized Biologist may be assisted by desert tortoise monitor(s) who have been approved by the Authorized Biologist, but the Authorized Biologist will remain the contact for Fort Irwin. Desert tortoise monitors will oversee all project construction activities with potential to affect desert tortoise. Desert tortoise monitors will ensure proper implementation of protective measures, record and report desert tortoise and tortoise sign observations in accordance with approved protocol, report incidents of noncompliance in accordance with the BO and relevant permits, and move desert tortoise from harm's way and place these animals in "safe areas" pre-selected by the Authorized Biologist(s) or maintain the desert tortoises in their immediate possession until an Authorized Biologist assumes care of the animal.
  Desert tortoise monitors will assist the Authorized Biologist(s) during surveys. Desert tortoise monitors will not be authorized to conduct desert tortoise presence/absence or clearance surveys unless directly supervised by an Authorized Biologist. "Directly supervised" means the Authorized Biologist is in direct voice and sight contact with the desert tortoise monitor.

The Authorized Biologist's duties will include:

- Be available to supervise, conduct, and coordinate mitigation, monitoring, and other biological resources compliance activities, particularly in areas requiring avoidance or containing sensitive biological resources, such as special-status species or their habitat.
- Clearly mark sensitive biological resource areas and inspect these areas at appropriate intervals for compliance with regulatory terms and conditions.
- Inspect active construction areas where animals may have become inadvertently entrapped within the area prior to the start of construction each day. At the end of the day, inspect for the installation of structures that prevent entrapment or allow escape during periods of construction inactivity. Periodically inspect areas with high vehicle activity (e.g., parking lots) for animals in harm's way.

During operation, the Authorized Biologist will be a Fort Irwin biologist.

7.3 Summary of Avoidance, Minimization, and Conservation Measures

Fort Irwin has designed the project to minimize direct effects to the desert tortoise and its habitat. In addition, Fort Irwin will employ BMPs in order to avoid, minimize, and prevent potential direct effects to desert tortoise or potential habitat. These measures include:

- Clearance surveys will be conducted prior to construction activities within the proposed solar site and prior to installation of the transmission line components.
- An Authorized Biologist will be onsite during initial site grading activities and any subsequent construction activities which would have the potential to affect desert tortoise. If a desert tortoise is found within or adjacent to the project site during construction or operation, an Authorized Biologist will move it out of harm's way in coordination and consultation with the USFWS.
- The construction site perimeter, including support facilities and the transmission line corridor, will be surrounded by temporary desert tortoise exclusion fencing. Controlled access gates, equipped with tortoise grates, will be installed at roads entering or exiting the solar farm site. The solar facility will be designed, operated, and maintained so that channelization of surface water flow will not undermine the integrity of the perimeter fence or the desert tortoise exclusion fencing.
- An erosion and sediment control plan will be implemented as part of standard Fort Irwin BMPs to prevent project-related construction effects on habitat outside the work areas.
- Following construction, permanent desert tortoise exclusion fencing will be constructed and maintained to prevent desert tortoise entry into the solar facility during operations.

8 Finding of Effect

Fort Irwin, acting as the lead federal agency, has determined that the proposed project **may affect and is likely to adversely affect the desert tortoise, but would not jeopardize the continued existence of** the desert tortoise. The proposed project would **not adversely modify or destroy** designated critical habitat for this species.

No other species protected under the ESA would be affected by the proposed action.

Summary

This natural resources report describes the existing biological resources for the proposed Fort Irwin National Training Center Solar Facility Project located in the City of Fort Irwin in San Bernardino County, approximately 37 miles (60 kilometers) northeast of Barstow, California. The project site covers approximately 380 acres of disturbed Mojave creosote scrub vegetation. The natural resources survey identified the vegetation communities, common species, and special-status species and their habitat present within the project area. The survey focused on federally listed desert tortoise (*Gopherus agassizii*) and included a protocol level survey on the entire project area.

Two live tortoises were found during the survey, and active or historic desert tortoise sign (active burrow, carcass, etc.) was found within the project area or in the survey's zone of influence.

Two sensitive bird species were observed on the project site (burrowing owl and loggerhead shrike).

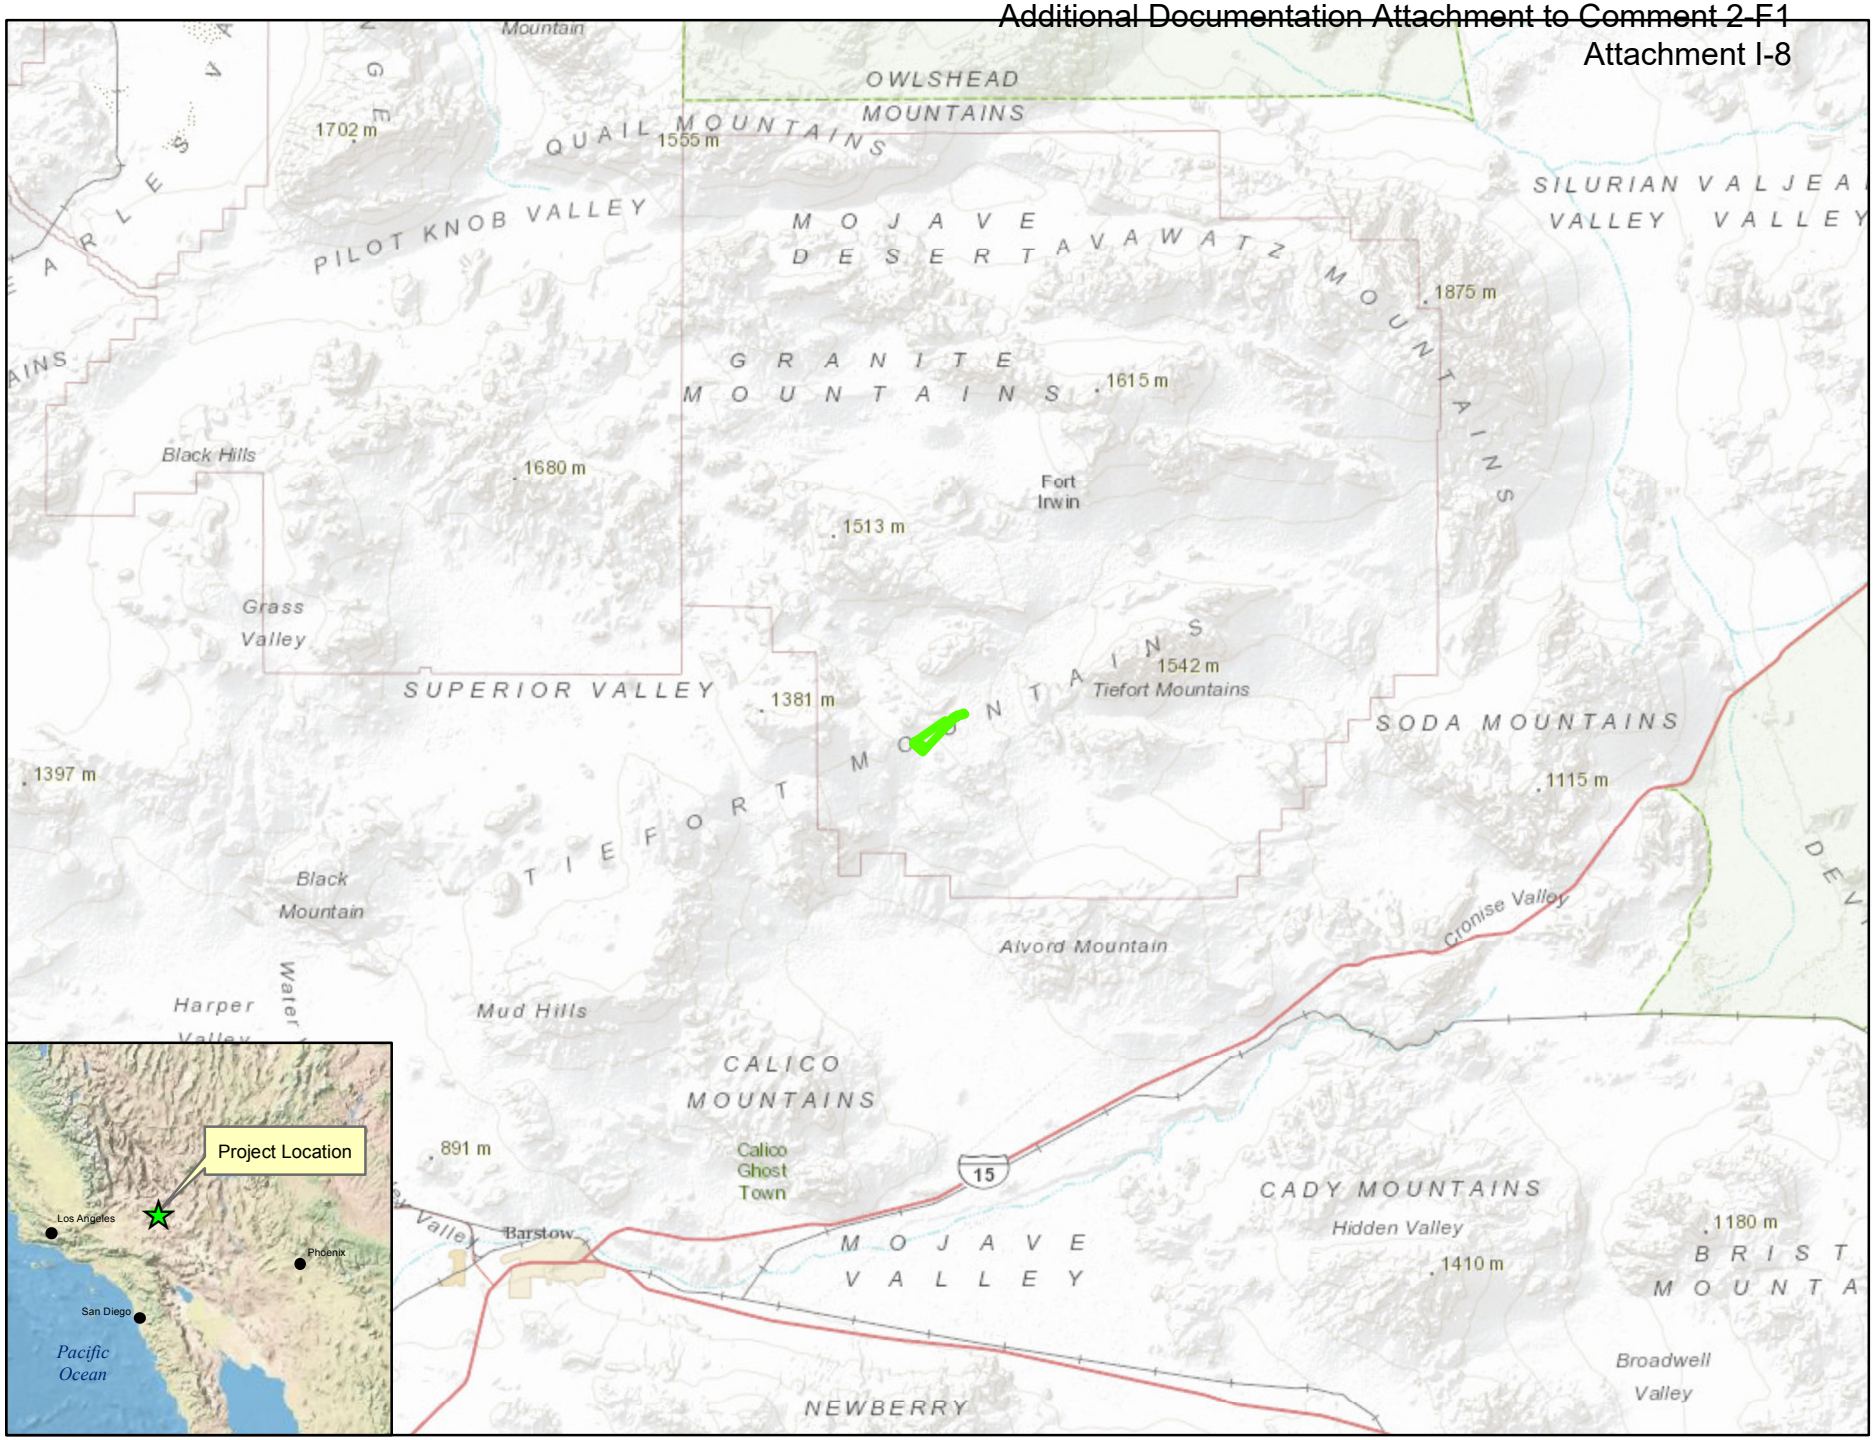
SECTION 1

Introduction

This report presents the results of a natural resources survey and protocol level survey for the federally threatened desert tortoise (*Gopherus agassizii*) to support analysis of the environmental impacts associated with the construction and operation of a solar facility at Fort Irwin, California. The natural resources survey was conducted to characterize the proposed solar facility area (approximately 380 acres) and to determine whether the desert tortoise or any other protected species occurs within the proposed project area.



1.1 Project Description

Fort Irwin is proposing to construct and operate a solar photovoltaic (PV) facility on up to 380 acres. The facility will include solar arrays, a battery energy storage system, access/maintenance roads, and an electrical tie-in. The proposed action is required to meet energy reduction requirements in Executive Orders and Department of Defense and U.S. Army mandates.

1.2 Site Location

Fort Irwin, also known as the National Training Center, is located in southeast California 37 miles (mi) (60 kilometers (km) northeast of Barstow in the Mojave Desert in northern San Bernardino County. Fort Irwin was designated as a permanent installation in 1961 and encompasses approximately 996 square mi (2,580 square km). The installation is approximately 25 mi (40 km) from Interstate 15 midway between Las Vegas and Los Angeles (Figure 1-1).

Fort Irwin serves at the Army's premier training center. Over half of the land area of Fort Irwin is used for desert battlefield training. One of the key training opportunities on Fort Irwin includes the use of an Opposing Force, which provides force-on-force and live-fire training for ground and aviation units in a joint scenario. The Fort Irwin cantonment area contains housing, administrative, medical, and other supporting facilities and encompasses approximately 3 square mi (8 square km).

SECTION 2

Methods

CH2M HILL biologists conducted a natural resources survey to identify and map federal and state threatened and endangered species habitat within the proposed solar facility site and transmission line corridor from March 26, 2012 through March 29, 2012. The project corridor extends from the main gate access road, west toward Tiefort Mountain. Together, the site and project corridor make up the project area.

2.1 Survey Methodology

The goal of the CH2M HILL survey was to determine the presence or absence of desert tortoises and any other listed species within the proposed project area. The survey was conducted within the proposed solar site and the transmission line corridor by a four-person team of CH2M HILL biologists, Jessica Birnbaum, Gabriel Dupree, Amy Hammontree, and Jason Speights.

The survey was conducted according to the 1992 Field Survey Protocol for Any Federal Action that May Occur within the Range of the Desert Tortoise (U.S. Fish & Wildlife Service [USFWS] 1992; USFWS, 1996; USFWS, 2010) by walking transects at 10-meter (m) spacing throughout all accessible, appropriate habitat on the proposed project site and walking transects within the surrounding zone of influence (ZOI). The ZOI survey consisted of three additional 10-m (approximately 30-foot [ft]) ZOI belt transects at 200-m (approximately 655-ft) intervals parallel to the northern border of the transmission line corridor (200-m, 400-m, and 600-m from the perimeter), in accordance with USFWS protocol for a linear site. The area where survey was conducted is shown in Figure 2-1.

- During the survey, information was collected by the following methods:
- Performing preliminary characterization of plant communities on the site.
- Taking photographs of the site (Appendix A).
- Recording all definitive sign of desert tortoises, including live tortoises, burrows, scat, carcasses, and shell-skeletal remains (Appendix A). Any tortoise or large mammal burrows encountered that could be used by tortoises were visually inspected. Very small burrows that could be used by juvenile tortoises but are much more often rodent burrows were also visually checked when encountered.
- Recording all other sensitive species sightings, including the federally endangered Lane Mountain milk-vetch (*Astragalus jaegerianus*) and other California sensitive plant and animal species. The Lane Mountain milk-vetch is known to occur at Fort Irwin, and designated critical habitat for the species has been identified south of the installation boundary.
- Recording sightings of all common plant and animal species.

Each biologist utilized a global positioning system (GPS) unit to orient and guide the survey. The location of any observed special status species sign was recorded using the GPS unit. All transect routes were generated prior to conducting the field work and uploaded into the Garmin hand-held GPS unit.

SECTION 3

Results

This section provides the results of the natural resources and focused desert tortoise survey, including site characteristics, plants, wildlife, and sensitive species.

3.1 Site Characteristics

Much of the land within the proposed Fort Irwin solar PV facility site has been historically disturbed by military training activities, including several shallow bomb craters. There was also evidence of previous all-terrain vehicle use within the site. The survey area ranged in elevation from approximately 792 m [2,600 ft] above mean sea level (msl) on the southeastern corner to approximately 975 m (3,200 ft) msl on the northwestern edge, and is characterized by creosote bush (*Larrea tridentata*)-white bursage (*Ambrosia dumosa*) series vegetation community (Sawyer and Keeler-Wolf, 1995 and Hollan, 1986). Creosote bush and white bursage are common throughout the site, while common associated species varied. Wildlife observed on the site was typical of that found in surrounding areas. No fish or amphibious species are likely to inhabit the site or immediately surrounding areas because there are no permanent water sources there. All wildlife and plants observed are listed in Table 3-1.

3.2 Sensitive Species

Nine sensitive species (four plants and five animals) were specifically targeted during the natural resources survey. The four plant species include the federally endangered Lane Mountain milk-vetch and three California state protected species: the alkali Mariposa lily (*Calochortus striatus*), Clokey's cryptantha (*Cryptantha clokeyi*), and the Mohave fishhook cactus (*Sclerocactus polyancistrus*). The five animal species include the desert tortoise (federally listed as threatened) and four state protected bird species: LeConte's thrasher (*Toxostoma lecontei*), burrowing owl (*Athene cunicularia)* loggerhead shrike (*Lanius ludovicianus*), and yellow-headed blackbird (*Xanthocephalus xanthocephalus*). These species were targeted due to the existence of historical records of occurrence in the project vicinity (California Native Plant Society (CNPS), 2012; California Department of Fish and Game (CDFG), 2012). Figure 2-1 depicts the locations for all desert tortoise and burrowing owl sign found, and GPS locations for each are provided in Table 3-2.

3.2.1 Sensitive Plant Species

3.2.1.1 Alkali Mariposa Lily

Alkali Mariposa lily is a CNPS List 1B.2 bulbiferous herb that blooms from April to June and is historically known to occur most commonly in open, flat, barren sites on the sandy margins of alkali depressions in creosote bush scrub and arid phase saltbush scrub communities at elevations ranging from approximately 70 m to 1,595 m (230 to 5,230 ft) msl. This plant was not observed during the natural resources survey and is not expected to occur due the lack of suitable habitat on the proposed project site (CNPS, 2012).

3.2.1.2 Clokey's Cryptantha

Clokey's cryptantha is a CNPS List 1B.2 annual herb that blooms in April and is known to occur in desert habitat, generally including sandy or gravelly soils within creosote bush scrub communities in the Mojave Desert from elevations of approximately 800 m (2,625 ft) to approximately 1,280 m (4,200 ft) msl. This plant was not observed during the natural resources survey, but it has a moderate potential to occur due to the presence of suitable habitat on the proposed project site (CNPS, 2012).

3.2.1.3 Lane Mountain Milk-vetch

Lane Mountain milk-vetch is a perennial herb that is federally listed as endangered. It is most commonly found in Mojave mixed woody scrub or creosote bush scrub. Habitat for the species is found at elevations of approximately 915 to 1,220 m (3,000 to 4,000 ft) msl with granite substrate, shallow soils with bedrock near the surface, relatively gentle slopes and areas of low ridges, diverse shrub assemblages in Mojave creosote bush scrub, and Mojave mixed woody scrub communities. It is almost exclusively found growing up through shrubs or occasionally through clumps of dead bunchgrass. This plant was not observed during the natural resources survey and is not expected to occur due to habitat on the proposed project site being marginally suitable to support the species (Calflora, 2012).

3.2.1.4 Mohave Fishhook Cactus

Mohave fishhook cactus is a CNPS List 4.2 shrub (stem succulent) that is generally found on basalt rock hillsides, limestone hillsides, and desert pavement, generally on south- to southwest-facing slopes. This plant

was not observed during the natural resources survey, but has a moderate potential to occur due to the presence of suitable habitat on the proposed project site (CNPS, 2012).

3.2.2 Sensitive Wildlife Species

3.2.2.1 Desert Tortoise

Desert tortoises were classified by the USFWS as a threatened species in 1990. This listing occurred as a result of continued human-caused habitat destruction through urban expansion, off-road vehicle use, illegal collection for the pet trade, and raven predation on juvenile tortoises.

The desert tortoise is listed as threatened in over 30 percent of its range. Desert tortoises occur in southeastern California, southern Nevada, southwestern Utah, and northwestern Arizona, often within desert scrub communities (USFWS, 2012).

Two desert tortoises were observed inside their burrows, as well as four other desert tortoise burrows that appeared to be active, with scat observed in or around the entrance of the burrow. One unhatched egg from 2011 was observed. A total of nine desert tortoise burrows were observed during the survey. One pallet, or a shallow depression constructed under low shrubs providing a temporary resting for the tortoise, was observed. Five relatively intact desert tortoise carcasses (indicating that the animals probably died within the past 1 to 2 years) were observed. Eight collections of shell-skeletal remains (indicating the animals had been dead a minimum of 2 years) were observed. See Table 3-2 for the locations of all desert tortoise sign found.

Notes:
DT = Desert Tortoise; BUOW = Burrowing Owl

3.2.2.2 LeConte's Thrasher

LeConte's thrasher is a California state species of concern and is protected by the Migratory Bird Treaty Act (MBTA). Home range is in saltbush-cholla scrub. Preferred habitat generally consists of sparsely vegetated desert flats, dunes, alluvial fans, or gently rolling hills having a high proportion of one or more species of saltbush or shadscale and/or cylindrical cholla cactus 0.9 to 1.9 m (approximately 3 to 6 ft) tall. It rarely occurs in habitats consisting entirely of creosote bush. The majority of shrubs in the project area rarely exceed 2.5 m (approximately 8 ft) in height, except for isolated desert trees, yuccas, or tall, thin shrubs. This species was not observed during the natural resources survey and is not expected to occur on the project site due to the habitat being marginally suitable.

3.2.2.3 Loggerhead Shrike

The loggerhead shrike is a California state species of concern and is protected by the MBTA. This species is relatively common in lowland California and prefers open habitat with scattered shrubs and trees for nesting (Grinnell and Miller 1944). Marginally suitable foraging habitat for this species occurs within the project area, and suitable nesting habitat is very rare. One individual loggerhead shrike was observed on the project site during the survey.

3.2.2.4 Yellow-headed Blackbird

The yellow-headed blackbird is a California state species of concern and is protected by the MBTA. The species generally occurs in California as a migrant or summer resident, but small numbers winter in the southern deserts. Preferred breeding habitat includes marshes and wetlands with tall emergent vegetation, and the blackbird may forage in surrounding wetlands, grasslands, and croplands. Yellow-headed blackbirds breed at scattered sites throughout the Mojave Desert. Small numbers breed regularly near Victorville, Barstow, and Newberry Springs in San Bernardino County. Marginally suitable foraging habitat for this species occurs within the project area, but no suitable nesting habitat occurs. The yellow-headed blackbird was observed on the project site during the survey.

3.2.2.5 Mohave Ground Squirrel

Mojave ground squirrel (Spermophilous mohavensis) is a California state-listed threatened species restricted to the Mojave Desert in San Bernardino, Los Angeles, Kern, and Inyo Counties. This species favors open desert scrub, alkali desert scrub, and Joshua tree habitats at elevations ranging from approximately 550 to 1,524 m (1,800 to 5,000 ft) msl. It is known to feed in annual grasslands. This species was not observed during the survey but has a moderate potential to occur on the project site.

3.2.2.6 Western Burrowing Owl

The western burrowing owl is a state species of concern and is protected by the MBTA. This ground-nesting raptor occupies burrows in annual grassland or ruderal habitats. It is known to occur in open, dry grasslands, agricultural and range lands, and desert habitats often associated with burrowing animals (CDFW, 1993). This species was observed on the project site (Table 3-1).

SECTION 4

Conclusions and Recommendations

This section presents conclusions about biological resources in the project area and presents recommendations concerning further surveys or permitting that may be required.

4.1 Conclusions

One federally threatened wildlife species and three wildlife California species of concern were determined to occur within the proposed project area:

- Desert tortoise (federally threatened)
- Burrowing owl (California species of concern)
- Loggerhead shrike (California species of concern)
- Yellow-headed blackbird (California species of concern)

Two active desert tortoise burrows were observed during the survey. Other California state-listed wildlife species observed include the burrowing owl, loggerhead shrike, and yellow-headed blackbird. No additional federally protected species or California protected wildlife species were observed during the field survey.

In addition, one California wildlife species listed as threatened and two state plants listed as sensitive are considered to have a moderate or higher potential to exist in the project area but were not observed during the survey:

- Mohave ground squirrel (California threatened species)
- Clokey's cryptantha (California sensitive species)
- Mojave fishhook cactus (California sensitive species)

4.2 Recommendations

A pre-construction survey may be required for the federally threatened desert tortoise. It is recommended that coordination with the CDFG and USFWS be conducted to ensure that no adverse effects occur to this species as a result of project construction.

A pre-construction nesting bird survey or avoidance/mitigation may be required for the loggerhead shrike to comply with the MBTA. Project activities may take place in areas of potential nesting for loggerhead shrikes. If project construction activities are to occur during bird nesting season (generally between February 1 and October 15), it may be necessary to conduct a nesting bird survey prior to vegetation disturbance as deemed necessary by CDFG.

The following surveys would be recommended and deemed necessary by CDFG, if a state permit is required for the project:

- A survey for Mojave ground squirrel may be recommended by CDFG depending upon the permitting needs for the project.
- A pre-construction survey may be required for burrowing owls within 30 days of the initiation of vegetation removal activities on the project site. This survey is typically required by CDFG and consists of walking 30-m transects throughout the project area to identify any owls currently inhabiting areas where project activities may disturb their burrows. During the non-breeding season (October-February) these owls can be passively relocated off the project site after completion of coordination and a relocation plan is approved by CDFG.
- Clokey's cryptantha and Mojave fishhook cactus have a moderate potential to occur at on the project site. A rare plant survey may be required by CDFG depending on project permitting needs.

Project Description

1.0 Introduction

1.0.1 Executive Summary- Description of facility

enXco Development Corp. proposes to develop "McCoy Soleil," a 300 Megawatt renewable energy resource incorporating Solar Reserve's "Solar Power Tower" concentrating solar power (CSP) technology. The proposed project, located approximately.10 miles northwest of the town of Blythe, CA, may use portions of 23 sections of BLM administered land, applied for under serialized application CACA 049490.

The technology that will be used at McCoy Soleil has been proven at the Department of Energy's Solar One and Solar Two facilities just east of Barstow. Solar Reserve holds the exclusive license to develop the technology proven at Solar Two and further refined since. Upon construction the project will consist of approximately 8500 heliostats each 120m2, sited over an approximate two and a half square mile solar field. At the center of that field would be a 600 ft. tower with a solar receiver at the top, two storage tanks at the base of the tower to store molten salt, and several other ancillary buildings also at the base. The project will be interconnected via a new 230kv interconnection at the proposed Midpoint substation approximately 14 miles away.

1.0.2 Schedule for project

McCoy Soleil is currently waiting for the first phase of the transmission study results before proceeding to the next major phase of development. At this time, enXco is predicting a COD of December 2013, to coincide with the predicted on-line date of the Devers Palo Verde 2 transmission project. Please see the Appendix for a detailed chart of the project schedule.

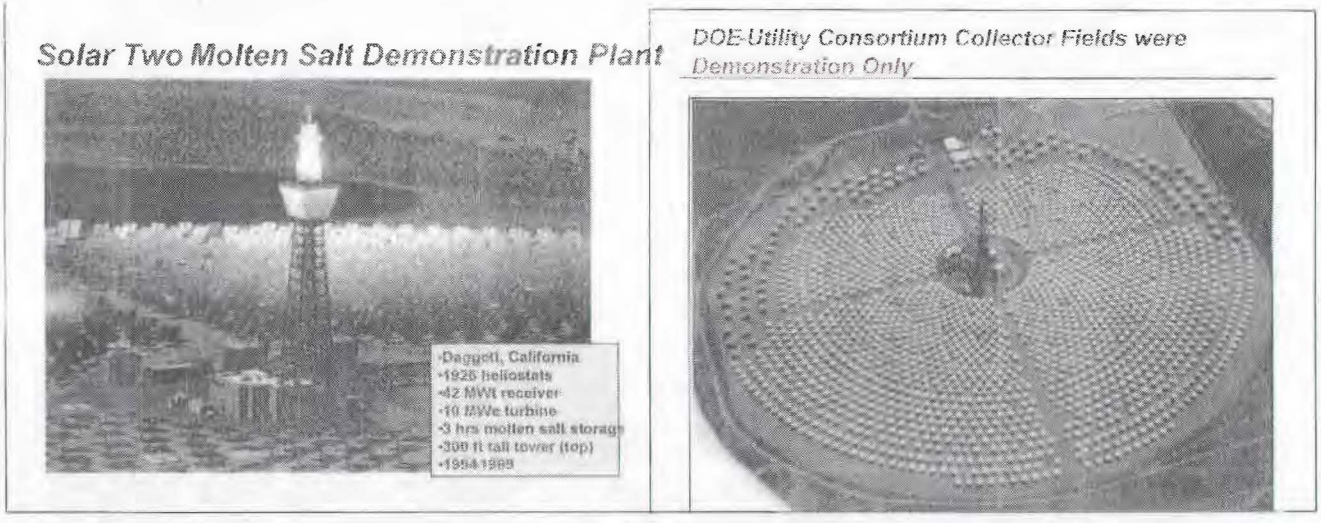
1.1 Proponent's Purpose and need for the Project

enXco is a renewable energy development and operations company which seeks to provide clean, renewable energy to the Southern California electricity system. California is currently experiencing increased load growth and requires new sources to meet demand. In addition, California has passed two important laws, instituting a statewide renewable portfolio standard (RPS) and greenhouse gas reduction plan (AB-32). The RPS currently requires independently owned utilities in California to purchase 20% of their energy from renewable sources by 2010. Governor Schwarzenegger signed an executive order, and the CA state legislature is currently writing a bill to require a 33% RPS by 2020. Utilities and other greenhouse gas (GHG) emitters in California will simultaneously need to reduce their GHG emissions through the implementation of AB-32.

Once operational, McCoy Soleil will be able to provide southern California with high value fully dispatchable electricity generated from a renewable resource. Because solar power produces energy during the peak energy demand, the resource is highly valued by utilities. Thus, McCoy Soleil will help the utility meet its renewable energy requirements, California meet its AB-32 requirements, and it will allow BLM to help meet the challenge of the Energy Policy Act of 2005 to install at least 10,000MW of non-hydro renewable generation capacity on public lands by 2015.

In order to select the best possible site for CSP development using BLM administered lands enXco used the following criteria for McCoy Soleil:

- **Solar Insolation** – This area of the Mojave desert ranks among the highest insolation values in North America, with a corresponding benefit to net capacity factor projections. This will result in a lower cost of electricity for California ratepayers.
- **Road and Transmission Access** – Parcel is located within an area that is readily accessible for roads and transmission right of way.
- **Distance to Point of Interconnect** – The proposed Midpoint substation is located approximately 14 miles to the south of the project boundary.
- **Size** – The heliostat field and power block will cover the majority of the project area. For detailed acreage requirements, please see Table 1.2.3 and the drawings in the Appendix.
- **Environmental Consideration** – Site screening took into consideration potential presence of endangered/threatened species, impacts on surface & groundwater, impacts on ecology & flora, impacts on terrestrial fauna, impacts on soils & agricultural potential, impacts on avifauna, impacts on cultural heritage resources, noise impacts, potential social and visual impact. Please see section 5.0 for a further discussion of environmental considerations.
- **Soil Conditions** – enXco has not yet completed a soil test to determine requirements for foundations for the solar array. Preliminary walk-through by civil engineers suggests that the foundations discussed in section 5.8 will be sufficient for geotechnical needs.



1.0.3 Technology overview

Once operational, McCoy Soleil will use the sun's energy to heat molten salt, which will be used to generate steam, on demand, in order to turn a traditional steam turbine. The unique aspect of this technology is its ability to store the sun's thermal energy in the form of molten salt for extended periods of time. By storing the sun's thermal energy a few hours or a few days, McCoy Soleil will be able to generate electricity at the times it is most critical for the utility to receive firm capacity, during peak and super-peak periods. Additionally, McCoy Soleil will be able to do what most solar based renewables cannot, deliver full capacity to the grid when it's cloudy, or even at night. Thus, McCoy Soleil will deliver zero emission, solar generation to SCE at the times it needs it most.

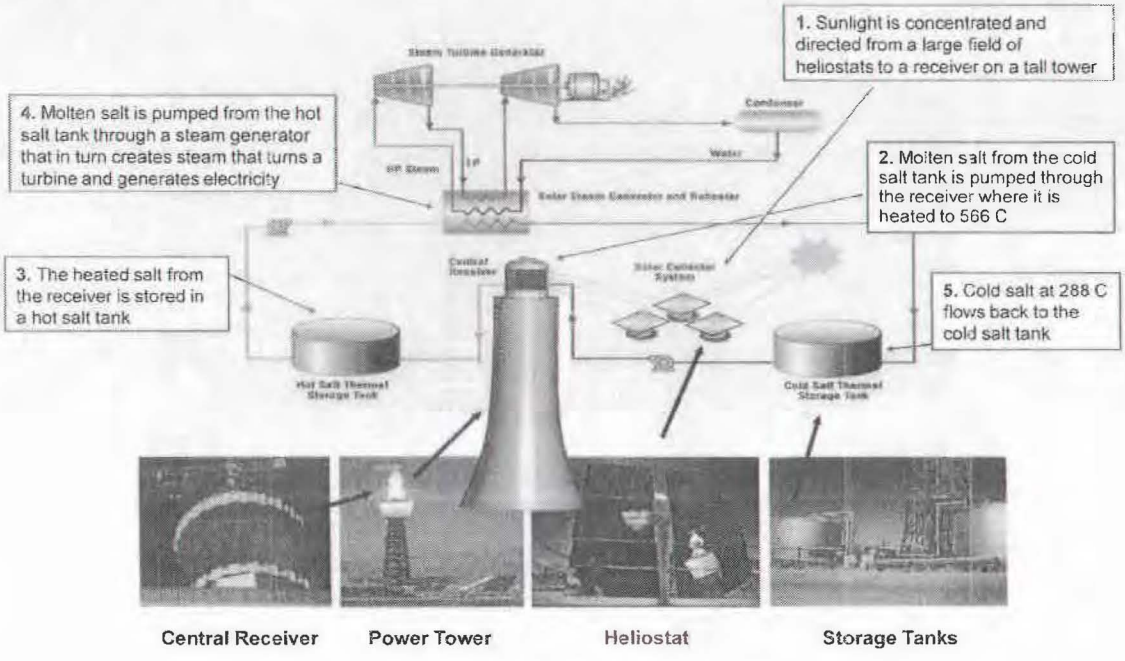
1.0.4 Technology History

The technology that will be implemented at the McCoy site was proven in a demonstration plant just west of Barstow, CA. The Department of Energy backed 'Solar One' and 'Solar Two' projects of the 1980s and 1990s were the first demonstration of the solar tower power technology that will be used at McCoy Soleil. Located just east of Barstow California, both Solar One and Solar Two were joint projects between the U.S. Department of Energy, the Solar Energy Research Institute (now NREL), Rocketdyne (now part of United Technologies) and a consortium of investor owned utilities. Solar One, which operated from 1982 to 1986, was based on direct steam generation technology. Without an ability to store the thermal energy, Solar One proved to be uneconomical as the loss of the sun's energy (e.g., clouds, night) resulting in a significant drop in plant performance. With Solar Two, Rocketdyne incorporated a molten salt loop in the plant enabling the efficient storage of thermal energy and the ability to continue to

generate power when the sun wasn't available. This also created the ability to deliver solar electricity 24 hours a day, the addition of thermal storage also created the ability to dispatch solar electricity when power is most needed during periods of peak demand. As a result, Solar Two demonstrated a significant increase in overall plant efficiency. Below are pictures of the Solar Two plant.

Pictures of Solar One and Solar Two

In the years since the completion of Solar Two, Solar Power Tower technology has been improved to enhance overall efficiencies and controls. Market conditions and the emergence of renewable portfolio standards have positioned the Solar Power Tower project incorporating molten salt technology as the solar technology with the greatest potential to make electricity competitive for utilities and grid operators. Solar Power Towers are currently being built in southern Spain, and Solar Reserve will have at least one plant operational prior to construction of McCoy Soleil, in order to prove out the technology at large scale.



1.0.5 Technology Description

The Solar Power Tower project provides the unique capability to efficiently store solar energy, thereby enabling solar electricity to be generated and dispatched when desired. The plant consists of three major subsystems: 1) a field of heliostats, 2) the molten salt system, and 3) a conventional steam turbine power generation facilities [see Figure 6]. The generation of solar power starts with the heliostats concentrating the solar energy onto a central receiver (step 1). This receiver consists of thin-walled tubes through which molten salt passes, absorbing the solar energy (step 2). The molten salt leaves the central receiver and proceeds to a storage tank, the "hot salt thermal storage tank" (step 3). Since the molten salt material is very efficient at storing solar energy, the Power Tower project provides a firm source of renewable power that can be dispatched when needed. The molten salt then moves through a heat exchanger, which transmits its energy to generate steam which is sent to a steam turbine generating electricity (step 4). After generation of steam in the steam generator heat exchanger, the molten salt is sent to another the cold salt terminal storage tank, (step 5), and the cycle is repeated.

Solar Power Tower with Energy Storage

SolarReserve

3

1.2 General Facility Description, Design and Operation

1.2.1 Project Location, Land Ownership and Jurisdiction

The site for McCoy Soleil is located in Riverside County, approximately 10 miles northwest of the town of Blythe, CA. Please see section 3.2 for a better understanding of the previous use of Solar Reserve's technology in the California Desert. McCoy Soleil's site consists of nineteen (19) full sections and three (3) partial sections that are administered by the Bureau of Land Management. Please see drawings in the Appendix for a overview of the site, and section 1.2.2 for the list of the BLM property sections considered for this project site. enXco will be siting the solar facilities in one of the two locations identified in the Appendix. At that time, enXco will be pleased to relinquish any unused portions of the application to BLM. Final siting will be determined after detailed biological field studies are completed in order to avoid the most sensitive habitats, such as Desert Wash Woodlands. Final road alignment will likewise be determined by biological and cultural studies.

The McCoy Soleil project location is crossed by a gas ROW through the middle which will be avoided by the solar facilities. The average slope of the land under consideration is under 1%, which makes it ideal for solar CSP. The sections in question contain dry washes that flow predominantly northwest to southeast towards Blythe, and are fed by McCoy Mountains to the northwest. It is enXco's goal to minimize disturbance to the desert washes. Please see section

1.2.10 and drawings in the Appendix for detailed information on stormwater drainage and erosion control.

In addition to the physical characteristics of the site, the area was selected due to its easy access via existing roads. The site is directly off of and easily accessed via the Kaiser Mine road, north of Interstate 10. Although the existing roads would be used to the extent possible, the existing dirt track will need to be upgraded to access the facilities, and unpaved roads would be constructed to serve as access roads from the existing road network to the facilities and heliostat field. Please see section 2.7 for further discussion of grading and roadwork that will be required, and the Appendix for maps and drawings indicating the preliminary road and heliostat layout.

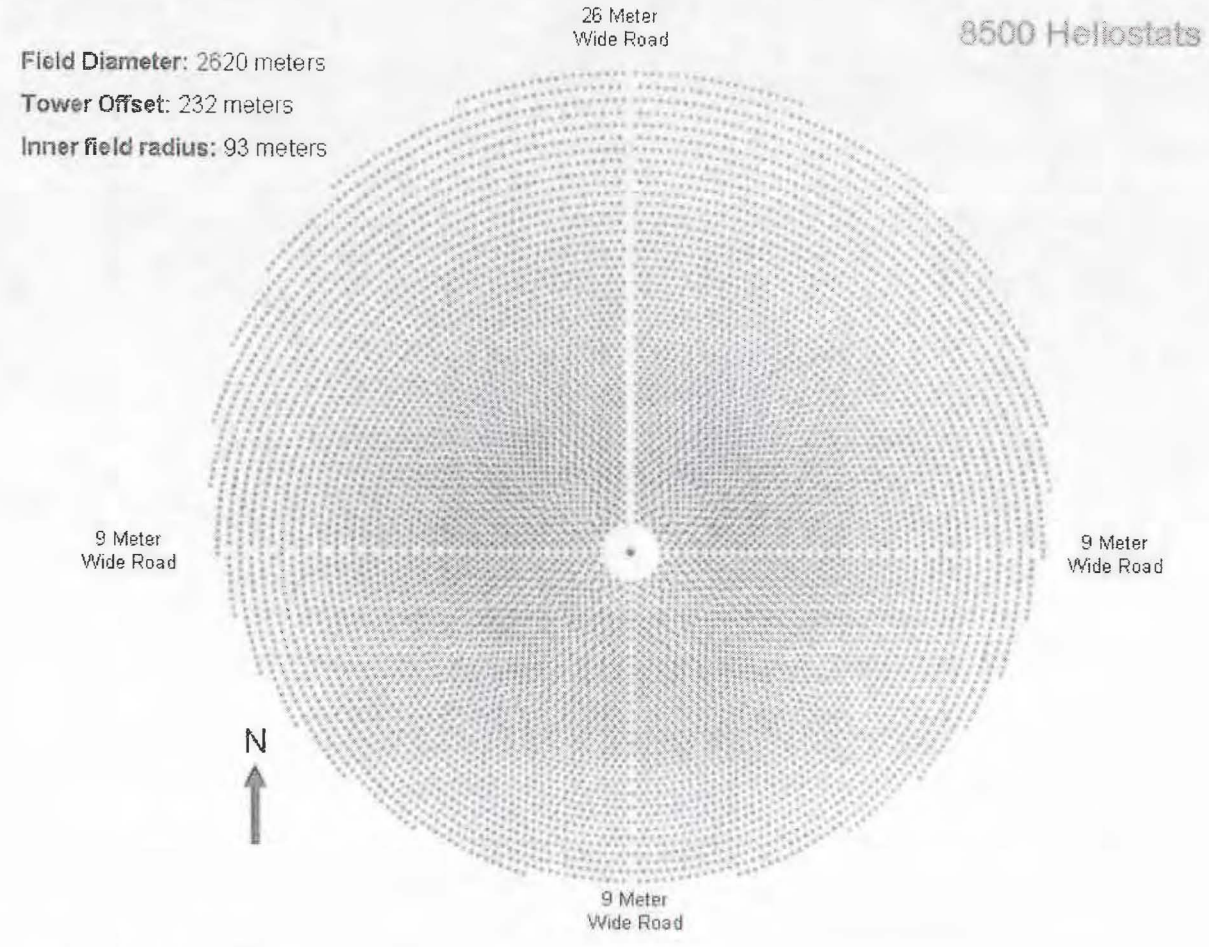
1.2.3 Total Acreage and general dimensions of facilities and components

Within the heliostat array fields, the power block area, the permanent facilities located around the perimeter road and in the temporary construction logistics area, clearing would be performed. All vegetation would be removed with a brush rake in order to separate the vegetation from the soil. The proposed disturbed area within the subject BLM right-of-way land is estimated to be 1808 acres. The new transmission line will disturb approximately 56 acres outside of the project area. The roadway to the site will follow an existing trail, but will disturb an additional 5.5 acres. The acres required for McCoy Soleil are described below and depicted in the drawings in the Appendix.

Estimated Overall Project Acreage		
Project Component	**Temporary (acres)**	**Permanent (acres)**
Current Right of Way	13959	13959
Transmission ROW (to be added to current 299 application)	136	136
Solar Heliostat Field	831	831
Operations and Maintenance Areas	8	6.4

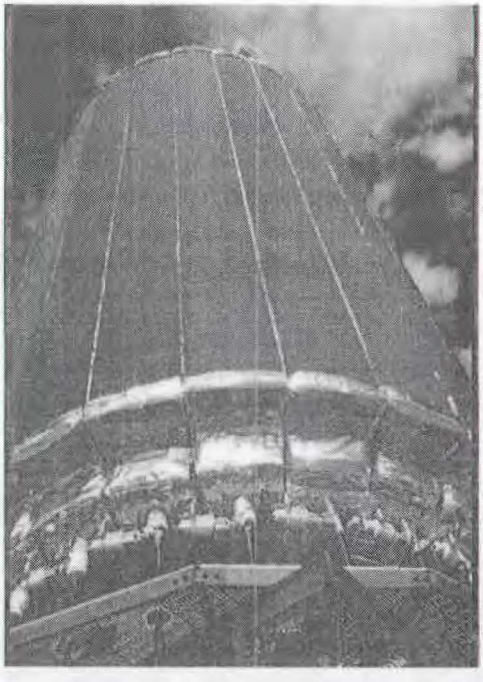


Switchyard	5	3.7
Roads outside project area	8	5.5
Construction Laydown Area	10	2
Transmission Lines disturbed	146	56
Total BLM acres disturbed	1911	1808

1.2.4 Numbers and General Dimensions of Solar Array

Approximately 8500 of these heliostats will be sited around the base of the tower. This sort of solar field technology is unique in that the siting of these heliostats is more flexible than the solar fields of other CSP technologies. By being somewhat modular in nature washes, hills, mounds and other micro-topography may be more easily avoided than in a typical trough plant. Thus a solar tower would require a fraction of the grading necessary for a trough plant, and will thus maintain the integrity of the soil surface. Though enXco anticipates it will have to site a portion of heliostats do to micro-topography, it will endeavor to keep the solar field as tight as possible so to limit the total area affected by the solar field.

enXco



SolarReserve Optimal Heliostat Layout

Solar Field optimal layout.

1.2.5 Towers, substations, transmission lines, access roads

At the center of the heliostat field will stand the receiver tower. The tower will be approximately 600 ft tall, with the solar receiver taking up the top 60 ft. The tower will be made predominantly of slipform concrete, with the solar receiver sitting on top and a few other ancillary elements like walkways and cranes to help service the receiver during scheduled maintenance. The receiver is made of a several panels and a multitude of thin-walled pipes through which the molten salt flows. To the right is an indicative picture of the solar receiver to be used at McCoy Soleil.

From the 'cold storage tank' below molten salt ~500°F will be pumped up the tower, it will flow through the pipes of the receiver and absorb the sun's thermal energy focused by the solar field. After absorbing the sun's heat the molten salt will flow back down to a 'hot storage tank' where the ~1000°F molten salt will be stored until it is pumped to a heat exchange which will generate steam to turn the steam turbine. Upon going through the heat exchanger, the cooled salt will be pumped back to the 'cold storage tank' closing the molten salt loop.

The nitrate salts used in the receiver are similar to that used in fertilizers, consisting of a 60:40 ratio of $NaNO_3$ (sodium nitrate) and KNO_3 (potassium nitrate). Since the molten salt loop is a closed system minimal salts will have to be added once the plant is operational. The small amounts of salt that would escape the loop are relatively harmless once cooled. After being swept up, these salts are innocuous and typically can be disposed of at any local landfill.

Please see the drawings in the Appendix for a diagram of the tower molten salt loop elements and steam turbine elements.

Preliminary layout and road design is based on detailed topographic maps and an on-site walk-through by civil engineers. Final service road alignments will also be dependent upon the final results of the environmental report documenting the results of field investigations. All standard engineering practices are incorporated into the road design and all applicable engineering designs will be applied to minimize soil erosion as caused by normal seasonal precipitation. The project access will use as much of the existing road structure as feasibly possible. Please see drawings in the Appendix for maintenance access road with culverts, typical road layout in the solar field, and road and erosion control treatments.

1.2.6 Temporary construction workspace, yards, and staging areas

enXco and our consultants are still engaged in designing the details of the construction process and will provide extensive drawings of temporary facilities during the NEPA process.

Temporary construction buildings will include 3-4 trailer offices for the management of the construction. enXco has not chosen a final location for these, but they will be along the northern border of the project area, in the vicinity of the entrance gate. Portable latrines will also be located in this area.

A small laydown area will be required adjacent to the heliostat assembly building of approximately 2 acres to accommodate delivery of materials, vehicles, etc. Additional parking and delivery of construction materials will utilize the future heliostat footprint, prior to its construction. Please see the Appendix for location and detail.

enXco does not anticipate that any additional land will be disturbed for laydown in the solar field. However, if additional temporary staging areas are required, they will be detailed in the EIS, and these will be restored to their prior condition once project construction is complete. No temporary disturbance is required outside the ROW application and final perimeter fencing. Please see the table of disturbed acres in section 1.2.3 for temporary and permanent acres required.

1.2.7 Geotechnical studies and data needs, including solar insolation testing

Preliminary geotechnical studies were conducted by civil engineers. The soils analysis was incorporated in the preliminary grading and drainage plan, and in the analysis of foundation requirements for the solar field. A more detailed study will be required as outlined below.

enXco plans to install a pyranometer to collect global horizontal and direct-normal solar radiation data from the site location in order to better predict solar plant electricity production. Installation of the ten (10) foot square non-penetrating cement pad, with solar testing equipment, and surrounded by 40-foot square fence will likely commence in early spring 2011 after the required EA is obtained and approved. The site for the pyranometer will be adjacent to the future O&M building and will be detailed in the EA for the testing ROW.

Additional testing needs that may be undertaken include:

- Aerial (LIDAR) survey to support detailed civil grading and drainage design;
- Hydrologic/drainage study including a regression analysis for detailed site drainage design and erosion and control plan;
- Geotechnical investigation, including borings, soil sampling, and ground penetrating studies for foundation and earthwork design, and dirt access road treatments;
- Test well program and aquifer testing to evaluate potential on-site groundwater sources;

All additional testing that may involve ground disturbance will receive an authorized permit by the BLM before commencement of activities.

1.2.8 Ancillary Facilities

Ancillary structures will include a 60'x 60' O&M building to house several on-site engineers and administrative personnel, small 50' x 50' heliostat assembly and storage shed for spare parts and a small parking area for workers. Please see the Appendix for placement of the facilities.

1.2.9 Water usage, amounts, sources

During Construction, water will be used to minimize fugitive dust as well as for other construction activities such as soil compaction. Based on expected soil moisture content and the optimal moisture of the soil necessary to achieve proper compaction, it is estimated that 1000 acre-feet (AF) of water will be necessary for the first year of construction. For subsequent construction years, 150 AF will be required for on-going dust mitigation. An on-site well will be permitted through the California State Division of Water Resources. Portable bathrooms will be provided during construction, as needed, and will be emptied offsite per regulations.

The proposed station is designed with a dry cooling tower for steam cycle cooling. This facility will require water for make-up of condensate due to normal relief valve losses and minor spills, general facilities and human consumption and water to wash the heliostats. Heliostat washing is a normal, continuous process that will occur regularly, with a wash water requirement of less than 70 acre-feet per year.

Water will be supplied from a well field developed at the project. A water tank will have a sufficient capacity for a one day operation at peak power generation. The water use can be divided into the following three categories based on the quality required:

(1) Service water which includes all other miscellaneous uses;
(2) Demineralized water for make-up to the steam cycle and mirror washing and
(3) Potable water.

The water will be treated using a conventional water treatment system to meet all plant needs. The plant will require a raw water storage tank, on the order of 2 million gallons, which will also contain a minimum of 300,000 gallons of water for fire protection capabilities. Steam cycle process water must meet stringent specifications for suspended and dissolved solids. This water will be processed by means of a demineralized water makeup system. enXco anticipates this will consist of multiple operations, concluding with mixed-bed demineralizers. The feedwater system will also include mechanisms to control dissolved oxygen, maintain a specific pH, and minimize scale formation. Demineralized water will also be used for the washing of heliostats. Potable water that meets regulatory standards for safe drinking water will be further treated on-site. The potable system will supply water to sinks, toilets, showers, drinking fountains, and emergency eye wash safety showers.

Water Consumption Requirements	Approximate Consumption during Construction	Approximate Consumption during Operation
Steam Cycle makeup water (AF)	0	100
Mirror wash water (AF)	0	70
Air cooled condenser augmentation (AF)	0	430
Construction year 1 (AF)	1000	0
Construction subsequent years (AF)	150	0
Total annual (acre-feet/year)	575 (2 years)	600

1.2.10 Erosion control and stormwater drainage

Once the earthwork grading and pad construction has been completed, the following storm water conveyance system and permanent BMPs will be placed. The site's final grade will be such that storm water from within the heliostat field will sheet flow to geocell lined service roadway swales that will convey flows to the southern portion of the project. The detained runoff will discharge offsite to existing natural drainage channels. The post-development sediment/retention basin and discharge points will provide storm water pollution prevention BMP controls along with retention time to reduce the peak offsite discharge to match pre-development conditions. The storm water discharge points will maintain the existing natural drainage course and will provide increased offsite drainage controls for the 100-year return storm event. Secondary storm water release greater than the sediment basin capacity will flow over the southern basin berm and roadway into the natural drainage channel without damaging the solar field improvements or adjacent down stream conditions. The discharge outlets will be constructed with rip rap, which will serve as an energy dissipater for heavy storm water discharge.

The offsite storm water run-on will sheet-flow to a perimeter geocell diversion channel with two controlled offsite concentrated discharge points. The upstream portions will also be protected with a perimeter road berm that will provide site protection from storm water run-on during a 100-year return storm event. The toe of the northern protective berm slope will be armored with soil cement cover and rip-rap to provide for slope erosion protection during a heavy storm event.

Storm water management calculations will be completed to develop drainage and erosion control protection for support of the construction activities, final grading, drainage system sizing for the 25-year return storm event; and the 100-year event flood control protection. These calculations will evaluate the following:

- Identify the site drainage patters and drainage areas for each phase of construction.
- Identify the design storm event
- Determine peak discharge rate
- Determine the required capacity for the drainage control systems
- Develop flood control protection elevations
- Design and size storm water control systems components

1.2.10.1 Erosion control and stormwater drainage BMPs

Construction and industrial operations at the site will be subject to the General Construction and General Industrial Storm Water National Pollution Discharge Elimination System (NPDES) permits, respectively. Compliance with these permits will require preparation and implementation of construction and operation Storm Water Pollution Prevention Plans (SWPPPs) that address the following requirements (among others):

- Identification of activities that may pollute storm water;
- Identification of Best Management Practices (BMPs) to control storm water pollution, including water erosion and wind erosion;
- BMP inspection, maintenance and repair;
- Training; and
- Site inspection and monitoring.

Erosion and sedimentation control BMP's will be designed and implemented to meet the requirements of the General Construction and General Industrial Storm Water NPDES permits as well as any requirements specified by the BLM.

The area of soil disturbance for the project would be kept to a minimum to limit wind and water erosion and enhance successful site rehabilitation/restoration. The areas of soil disturbance would be limited to pipeline alignments, transmission lines, access roads, construction support areas, and the heliostat, power block and operational support facilities.

Soil stabilization measures would be used to prevent soil being detached by stormwater runoff or wind erosion. The Applicant would employ temporary and permanent BMPs to protect the soil surface by covering or binding soil particles or preventing the concentration of runoff. The project would incorporate erosion-control measures required by regulatory agency permits and contract documents as well as other measures selected by the engineer. Site-specific BMPs

would be identified in the SWPPP, with final selection and design by the engineer, and associated figures to be included in the final active project SWPPP.

Project design features and or mitigation measures that will aide in the protection of soil resources could include at a minimum:

- Erosion and sedimentation control calculations performed to verify acceptable stormwater velocities, calculate BMP clean out frequencies and to size rip rap.
- Construction and final drainage designed to promote sheet flow, avoid un-necessary concentration of runoff, and control runoff velocity.
- Stone filters and check dams strategically placed throughout the Site to provide areas for sediment deposition and to promote the sheet flow of stormwater prior to leaving the Site boundary. Where available, native materials (rock and gravel) would be used for the construction of the stone filter and check dams. A stone crusher may be provided on site to utilize local stone for the production of gravel.
- Diversion berms, culverts and water bars would be utilized to redirect stormwater.
- Diversion channels would be armored as required to prevent erosion and scouring.
- Flat detention/infiltration ponds and ditches would be used.
- Where possible, maintenance roads would be designed not to disrupt regional flow patterns.
- Silt fences would be utilized extensively during each phase of construction to minimize wind and water erosion. Silt fence locations have yet to be determined and would be provided on the 90% engineering drawings.
- In areas of temporary disturbance (e.g., pipeline or transmission line alignment, temporary construction support areas), the surface would be recontoured to promote sheet flow and restore and match the original or surrounding drainage function. Native vegetation would be restored to promote healing of the landscape.
- Periodic maintenance conducted as required after major storm events and when the volume of material behind the check dams exceeds 50 percent of the original volume. Stone filters and check dams are not intended to alter drainage patterns but are intended to minimize soil erosion and promote sheet flow.
- Erosion and Sedimentation control BMP design would be in accordance with applicable government codes and standards.

1.2.11 Vegetation treatment and weed management

Excavation will require the removal of all vegetation from the areas to either be excavated (cut) or filled, which include the powerblock and tower, access roads, laydown, parking and O&M facilities. Vegetation under 18" may be able to be maintained within the solar field. At a minimum, all vegetation between every other row will be cleared with a blade to reduce the risk of fire and allow construction and maintenance access. Scarifying by blade will disturb the soil

to several inches and potentially allow some roots to remain to assist in soil stabilization and reduce the possibility of erosion. These scarified areas will serve as the access roads for both installation and continued maintenance and cleaning of the heliostat field. As such, they will be moderately graded to allow regular access with a pick-up truck-mounted tanker for washing. Continued weed management in cleared areas would be maintained through targeted application of herbicides such as Roundup® and/or by occasional scarification. Additional soil disturbance by regular operations of the plant is not expected.

enXco will develop a Weed Management Plan (WMP) for McCoy Soleil that describes non-native, noxious or invasive weed species that occur or are likely to occur at the site and prescribes management actions that may be taken to monitor and eradicate specified species. The WMP will also describe applicable regulations for the use of herbicides on federally managed lands in California, and provide the basis for proper management and use of herbicides at the site.

Typical operations and maintenance requirements for native landscapes are low once established. The WMP will include weeding, annual pruning, and soil monitoring if necessary. Weeding should occur frequently during the initial growth period to ensure that invasive plants do not mature and set seed. Weeding activities will follow the approved WMP. Once the native plant species are established, weeding frequency will drop to less frequent levels.

Vegetation will be allowed to re-grow within the heliostat field to the extent that it doesn't interfere with the movement of the heliostats. Vegetation will not be allowed to grow above 18". The access roads will be kept clear of vegetation and maintained as described further in section 4.1.

1.2.12 Waste and hazardous materials management

The McCoy Soleil project will be designed, constructed, operated and maintained to ensure the safe use and storage of hazardous materials. Storage, handling, and use of all chemicals will be conducted in accordance with applicable laws, ordinances, regulations and standards. Chemicals will be stored in appropriate chemical storage facilities. Bulk chemicals will be stored in storage tanks, and other chemicals will be stored in returnable delivery containers. Chemical storage and chemical feed areas will be designed to contain leaks and spills. Workers will be trained to handle hazardous wastes generated at the site.

Once construction is complete, McCoy Soleil will have minimal hazardous and non-hazardous waste at the site. The molten salt is a combination is a 60:40 ratio of Sodium Nitrate ($NaNO_3$) and Potassium Nitrate (KNO_3), in their sold form these two salts are traditionally used as elements in garden fertilizer. Since the salts are only used as a thermal working fluid and are not consumed, it is used continuously for the life of the plant without need for re-processing. Occasional spills of small quantities of salt from a leaking gasket quickly freeze and are picked up by plant staff and put into a waste receptacle. Depending upon the rules of the local jurisdiction this salt can be reused or disposed of in a landfill. At the end of the Solar Two demonstration period, the salt was solidified onsite and sold for fertilizer.

In addition to small quantities of salt which may leak, the turbine plant drains flow to an oily waste separator common to many steam plants and the waste removed by vacuum truck to a qualified facility. This fluid may contain lubricants and oils common to the turbine generator island. The quantity of this waste should be no different than for a similar steam unit of comparable size. Where possibilities exist for spills to occur from plant operations, catchment areas will be constructed to contain the spill. For example, the steam turbine will be sited on a cement pad with integrated containment that can control a possible catastrophic spill. Waste containing high metal concentrations, will be temporarily stored on site in portable tanks, and disposed of off-site by a chemical cleaning contractor in accordance with applicable regulatory requirements.

Electric equipment insulating materials will be specified to be free of polychlorinated biphenyls (PCBs).

Safety showers and eyewashes will be provided adjacent to or in the area of all chemical storage and use areas. State approved personal protective equipment will be used by plant personnel during chemical spill containment and cleanup activities. Personnel will be properly trained in the handling of these chemicals and instructed in the procedures to follow in case of a chemical spill or accidental release. Adequate supplies of absorbent material will be stored on-site for spill cleanup.

Other wastes generated on site will include those typical of a commercial building, such as computer and electronic equipment, paper, food scraps, cleaning agents, oily rags, oil and gasoline for vehicle use, etc. All wastes will be disposed of according to applicable LORS. In addition, no food wastes will be available for wildlife such as ravens to scavenge.

1.2.13 Fire Protection

Fire protection will be provided to limit risk of personnel injury, property loss, and possible disruption of the electricity generated by the project. Fire protection starts with reduced flammable materials in the solar field, including vegetation. This is one of the primary reasons that some vegetation will be removed from the site prior to construction of the solar field. Fire prevention will also be dependent on secure fencing of the site, as described elsewhere. Fire protection also includes appropriate access to all areas of the solar field by fire truck, with turn-around areas. Thus, final plans of the solar facilities will be inspected by local fire marshals for sign-off.

A Fire Protection and Prevention Plan will be prepared for construction and operation of the facility. The plan will include measures to safeguard human life, preventing personnel injury, preservation of property and minimizing downtime due to fire or explosion. Fire protection measures will include fire prevention methods to prevent the inception of fires. Of concern are adequate exits, fire-safe construction, reduction of ignition sources, control of fuel sources, and proper maintenance of fire fighting systems.

During construction, the permanent facility fire suppression system will be placed in service as early as practicable. Prior to installation of the facility's permanent fire suppression system, fire

extinguishers and other portable fire fighting equipment will be available onsite. These fire extinguishers will be maintained for the full construction duration in accordance with local and federal OSHA requirements.

Locations of portable fire extinguishers will include, but not necessarily be limited to office spaces, hot work area, flammable storage areas, and mobile equipment such as work trucks and other vehicles. Fire fighting equipment will be marked conspicuously and be accessible at all times. Portable equipment will be routinely inspected, as required by local and federal LORS, and replaced immediately if defective or in need of charge.

Sprinkler Systems will be installed in the Administration and Operations Building as required by National Fire Protection Association (NFPA) and local code requirements. Handheld fire extinguishers of the appropriate size and rating will be located in accordance with NFPA 10 throughout the facility. The plant will have a minimum of a 3,000,000 gallon raw water storage tank, of which 300,000 gallons will be dedicated to fire protection. One electric and one diesel-powered backup water pump, with a capability of 3,000 gallons per minute, will deliver water to the fire protection pipe system. A smaller jockey-pump will be used to maintain water pressure within the pipe system.

The area with highest fire risk is the power block and tower, as well as the auxiliary and control buildings and the fire protection system will be concentrated on these resources.

1.2.14 Site Security and fencing during construction and operation

Site security will be of the utmost importance due to the high value of the equipment used in construction of McCoy Soleil, and the safety of personnel and the public. At the onset of construction, site access will be controlled for personnel and vehicles. A security fence, which will also be the permanent fence, will be installed around the plant site boundary. At this time, all required laydown areas are expected to be contained within the defined project boundaries, and thus no additional temporary fencing will be required. In addition, security will be enhanced with motion detectors, facility lighting, and cameras in key locations. Care will be taken to prevent undue light pollution from the nighttime security lighting. Exterior lighting will comply with current title 24 regulations from the State of California, limiting uplighting and light pollution from exterior fixtures. Security will be maintained as required by the EPC contractor or a suitable subcontractor to maintain public safety and the security of the facilities.

Security fencing will be erected around the entire perimeter of the project area, with an access gate in the west corner prior to beginning construction. An emergency gate will be in the southwest corner, with access to the existing dirt road..Site perimeter fence will be 8 feet high and have an overall height of no more than 10 feet from the bottom of the fabric to the top barbed wire. The fence will have top rail, bottom tension wire, and three strands of barbed wire mounted on 45 degree extension arms. Posts will be set in concrete.

Controlled access gates will be located at the entrance to the facility. Site gates will be swing or rolling type access gates. Access through the main gate will require an electronic swipe card, preventing unaccompanied visitors from accessing the facility or construction area. All visitors will be logged in and out of the facility during normal business hours. Visitors and non-

employees will be allowed entry only with approval from a staff member of the facility. Visitors will be issued passes that are worn during their visit and returned to the main office when leaving. The facility will be staffed 24 hours/day and 7 days per week to maintain security. Even when the facility is not generating electricity, personnel will be present for maintenance and site security.

To reduce offsite lighting impacts, lighting at the facility would be restricted to areas required for safety, security, and operation. Exterior lights would be hooded, and lights would be directed onsite so that light or glare would be minimized. Low-pressure sodium lamps and fixtures of a non-glare type would be specified. Switched lighting would be provided for areas where continuous lighting is not required for normal operation, safety, or security; this would allow these areas to remain un-illuminated (dark) most of the time and thereby minimize the amount of lighting potentially visible offsite.

1.2.15 Electrical Components, new equipment and system upgrades

Power will be generated by the steam turbine generator (STG) and stepped up through the generator step-up transformer to the utility high voltage system. The generator shall be connected to the step-up transformer by isolated phase bus duct. A low-side generator breaker shall be provided between the generator and the generator step-up transformer (GSU).

The main generator will be synchronized to the utility's transmission system using the generator breaker. The STG will be supplied with metering quality current and potential transformers and meters capable of supplying signals to the control system and performance monitoring system.

A two winding, delta-wye GSU transformer will be designed according to the Institute of Electrical and Electronics Engineers Standards (IEEE) C57.12.00-2000 and supplied for the STG generator. The neutral point of each high voltage (HV) winding will be solidly grounded. The GSU transformer will have metal oxide surge arresters adjacent to the HV terminals.

Accessories will include a local visual enunciator, magnetic liquid-level gauge, pressure-relief device, sudden pressure relay, oil preservation device, valves for top and bottom filter press connections, drain/sampling valves, grounding pads, bushing-mounted current transformers, combustible gas detector, on-line dissolved gas/water monitor with 4-20 milliamp signal out to the controller, and hot spot winding temperature elements.

The GSU will include manual de-energized tap changers located in the HV windings with taps ranging from 5 percent above normal to 5 percent below normal in 2.5 percent increments. GSU transformer auxiliaries will be powered from two 480 V, three-phase, three wire sources for each transformer. Each power supply will be fed from separate sources and routed in separate conduits.

A two-winding, delta-wye UAT transformer will be designed according to the IEEE Standards C57.12.00-2000 and supplied for 4,160 V service. The UAT will be rated to supply facility

startup and maximum operating power requirements. A system calculation showing all connected equipment loads for the UAT transformer will be used to determine the requirements prior to procurement of the UAT. The neutral point of the UAT low voltage (LV) winding will be 1,000 amp (A) low-resistance grounded.

A plant electrical building will house the 4,160 V switchgear, 4,160 V motor controllers, low voltage switchgear, low voltage motor control centers, control panels, power and lighting panels, uninterruptible power supply (UPS), DC station batteries, DC switchboard, and other miscellaneous equipment, steam turbine control equipment and the control I/O cabinets.

The medium voltage switchgear will be single-ended, rated 4,160 V nominal, three-phase, three-wire with ratings not to exceed 3,000 A continuous and the calculated fault current duty. The medium voltage switchgear will receive power from the unit auxiliary transformer through non-segregated phase bus duct.

The medium voltage switchgear lineups will be located indoors, will use vacuum interrupters, and will be rated to continuously distribute the full auxiliary load. Each lineup will contain auxiliary power metering and voltage transformers, a main incoming breaker, and feeder breakers as necessary to distribute the load. All medium voltage breakers will be electrically operated from the control system and equipped with a stored energy mechanism. Breakers will be provided with remote racking mechanisms.

The emergency power for the plant switchyard and other plant critical loads will be supplied by the 125 volt DC (VDC) station battery system.

1.2.16 Interconnection to electrical grid – gen-tie

The project will be connected to the existing SCE transmission system via the Conceptual Midpoint substation located approximately 14 miles south of the project site. The interconnection map, Figure 2 in the Appendix, shows proposed interconnection route approximately 14 miles in length from McCoy Soleil to the proposed Midpoint substation. Results from the System Impact Study from SCE/CAISO are expected by spring of 2010.

McCoy Soleil will likely connect to the SCE line by construction of a single-circuit three-phase 115kV or 230 kV transmission line that would interconnect to the conceptual Midpoint substation. Foundations for the transmission line structures consist of single concrete piers reinforced as necessary to withstand design loads. The poles are approximately 80 feet in height with a span length expected to average approximately 500 feet. As identified in map 4, interconnection route (a) and (b) are both designed to follow major roads, railroads, and other ROW to minimize impact of further road building. Service roads will be required, if they do not already exist, to access the interconnection line. Final path will be subject to results of the Facility Study by the California ISO, final detailed designs, and the secured route easement.

enXco

1.2.17 Spill prevention and containment for construction and operation

Spill Prevention Control and Countermeasure Plans (SPCC) - SPCC Plans will be prepared for construction and operation of the site. The plans will include spill prevention and countermeasures procedures to be implemented including (but not limited to) a spill record (if applicable), analysis of potential spills, description of containment facilities, fill and overfill prevention facilities, spill response procedures, personnel training and spill prevention.

No equipment in the solar field will require containment structures. Only the power tower, powerblock, cooling and substation equipment in the central receiver location will require containment structures, as shown in Figure 4. Again, all equipment will be free of PCBs. The substation pad will be designed to capture any spills of insulator material.

Domestic wastewater will be treated and disposed at the site using a septic disposal system consisting of septic tanks and leach field permitted with the Riverside County Health District. Construction and maintenance vehicles will be maintained in accordance with manufacturer recommendations to minimize the risk of vehicle spills.

1.2.18 Health and Safety Program

As on of the largest independent operators of wind farms in the United States today, enXco is proud of its track record on safety. enXco plans to transfer lessons learned and the high quality of its wind safety program to the construction and operation of large-scale solar plants.

Safety of personnel will remain the Operator's top priority at the plant. The Safety Manual delineates the methods for meeting this goal. This manual will be kept up-to-date with government laws, regulations and policies as well as prudent industry practices.

Annual familiarity training will be conducted with the local authorities, including police and fire departments, as appropriate. Annual First Aid and CPR training will also be conducted.

A Safety Committee, with representatives from maintenance and operations personnel, and chaired by the Plant Manager, will be established. It will meet at least quarterly to review overall personnel and plant safety and make recommendations to the Owner for improvements to plant and personnel safety that are beyond the scope of the Operator. The Safety Committee will maintain a safety incentive program for all plant personnel.

There will be safety meetings for all employees at least monthly to conduct training as well as review procedures and lessons learned from other plants in the area of personnel and plant safety.

Weekly site Safety Surveys will be conducted to verify and inspect the entire plant site. They are intended to look at safety equipment status, signs properly posted and safety equipment operation. The safety program will be evaluated periodically by site wide emergency drills.

There will be continuing training conducted for all plant personnel on current industry issues as well as new changes to safety equipment and procedures.

The Operator will work and cooperate with the Owner's insurers to implement safety recommendations and assist in conducting site inspections.

An Emergency Response Plan will be developed and implemented to provide an integrated procedure for response to oil and hazardous materials spills, plant evacuation, medical/fire/law enforcement, and severe weather emergencies. The Emergency Response Plan will be consistent with applicable laws and regulations governing such emergencies.

1.3 Other Federal, State and Local Agency Permit Requirements

All construction, operation and maintenance activities associated with the proposed project would be conducted in compliance with all relevant federal, state and local regulations and permit requirements. The table at the end of this section details the preliminary list of required permits and authorizations that enXco may be required to obtain prior to construction and operation of the facility.

The primary agency responsible for issuing a permit for the solar facilities will be the BLM, which will issue a Right of Way (ROW). Under federal law, the BLM is responsible for processing requests for ROW to authorize projects such as this one, and associated transmission lines and other appurtenant facilities to be constructed and operated on land it manages. In processing applications, BLM must comply with the requirements of the National Environmental Policy Act (NEPA), which requires federal agencies to consider the environmental impacts associated with projects constructed and operated on their land. In the case of this project, this would be accomplished through the preparation of Draft and Final Environmental Impact Statements (EIS). This process will take approximately 18-24 months from the issuance of a Notice of Intent (NOI) by the BLM in the federal register.

The Bureau of Land Management (BLM) and California Energy Commission (CEC) signed an MOU for solar development that sets up a joint process by which the two agencies will work together to permit solar thermal power plants. This process allows the agencies to coordinate pre-application, data adequacy, discovery, analysis, hearings and proposed decisions. Final permitting approval of the plant will be made by the CEC, while the BLM will prepare a final record of decision (ROD).

The primary document and process that will satisfy the requirements of NEPA and CEQA is the Application for Certification (AFC) that is filed with the CEC. The AFC will assist in coordinating the necessary permits and communication among federal, state and local jurisdictions.

Separate consultation requirements and associated documentation are required for Section 106 of the National Historic Preservation Act and Endangered Species Act (ESA) section 7, should they be required. These consultations will be completed by BLM. BLM is also responsible for Native American consultation, including Government to Government consultation. The result of this cooperative effort is intended to result in a public participation process and environmental document that fully meets BLM requirements.

enXco is in preliminary stages of preparing the AFC, and plans to meet with the CEC for a pre-hearing after final land control is established and initial environmental surveys are complete. A complete list of required permits will be generated after the initial environmental surveys are complete. In [Figure 16], enXco has identified the agencies, permits and timeline that will likely be required for McCoy Soleil.

enXco will also meet with BLM to satisfy the BLM requirements under NEPA, and understands that clear communication and early information will help BLM in this regard. enXco will strive to prepare and release a preliminary draft of the EIS equivalent during the AFC preparation process so that BLM might have up to 60 days to review before AFC submission with the CEC. Sections that would be particularly helpful to BLM have been identified as existing conditions, proposed alternatives, and biological resources.

Preliminary List of Required Permits and Permit Schedule

Required Permits and Permit Schedule		
Air Quality	DOC	An application will be submitted to the South Coast Air Quality Management District (SCAQMD) about the same time as the NEPA documents to obtain a determination of compliance (DOC).
	Federal Title V	May require Federal Operating Permit.
Biological	BLM Fieldwork Authorization	A Fieldwork Authorization will be required from BLM to complete the detailed biological studies for McCoy Soleil.
	Federal Endangered Species Act, HCP/Incidental Take Permit	Wildlife surveys will need to be completed and if endangered species are found, submitted to the U.S. Fish and Wildlife Service (USFWS) for agency approval under the ESA Section 7 Consultation. Depending on findings in the environmental surveys, enXco may require a Low Effect Habitat Conservation Plan for McCoy Soleil. An Incidental Take Permit (ITP) may be required under section 10 of the ESA. BLM will consult with the USFWS regarding the presence of desert tortoise.
	California Department of Fish and Game (CDFG) Incidental Take Permit (ITP)	Wildlife surveys will need to be completed and if endangered species are found, submitted to the CDFG for agency approval. Depending on findings in the environmental surveys, enXco may require an ITP under section 2081 (b) and (c) of the CA Endangered Species Act.
	USFWS and CDFG 2080.1 Consistency Determination	Submit the federal USFWS opinion incidental take permit to the CDFG to obtain concurrence of federal ITC
	RWQCB	It is anticipated that the RWQCB will take jurisdiction of the ephemeral drainages. Pre-notification will be required to obtain an individual permit.

Cultural	BLM Fieldwork Authorization and Cultural Resource Use permit	A Fieldwork Authorization will be required from BLM to complete the Class 3 cultural studies for McCoy Soleil. Any removal of archaeological resources will require a Cultural Resource Use permit from the BLM.
	Historic Preservation Act section 106 consultation	Consultation with the SHPO will be required if the project would affect any property listed in the NRHP; any new site would require NRHP eligibility evaluation
Geological and Soils	BLM Building permit	The BLM requirement will be specified in the Conditions of Approval pending approval of the ROW application
	BLM Grading permit	The BLM requirement will be specified in the Conditions of Approval pending approval of the ROW application
Hazardous Material	Unified Program Facility Permit	Riverside County Fire Department, Haz Mat division, requires a permit prior to storage of hazardous materials on site.
	Aboveground Storage Tank permit	Riverside County Fire Department, Haz Mat division, requires a permit prior to storage of hazardous materials in aboveground storage tanks on site.
Land Use	ROW for Solar Energy Development/NEPA Review	BLM for commercial solar facility, including transmission lines and access roads. BLM will publish an EIS for the project.
	ROW for Solar Energy Testing	BLM for solar testing equipment, prior to the ROW grant for Solar Energy Development
Paleo	BLM fieldwork authorization	No state or local permits will be required. A BLM Fieldwork Authorization will be required for paleo studies.
Transportation and Traffic	NDOT and Caltrans: Oversize load permit	California Department of Transportation requires permits for any oversized (gross weight or dimensions) vehicle deliveries. At least 10 days prior to oversize loads At least 7 days prior to oversize load on State Highways.
	Encroachment permit (for work in County ROW)	Submit plans showing work 30 days prior to construction work in public ROW
	Haz Mat Permit	Federal Motor Carrier Safety Administration; depends on nature of hazardous material transported
	FAA	FAA Form 7460-1; at least 30 days before the application for a construction permit is to be filed

Hazardous Waste	EPA ID No. and register as a Hazardous Waste Generator with Department of Toxic Substance Control	Takes 7-10 business days once the application form has been received
	Hazardous waste generator permit from Riverside Co EHS	Approximately 30 days prior to approval once Business Plan is complete
	Waste Discharge Requirements	Regional water quality control board may require permits
Water Resources	Section 404 Permit U.S. Army Corps of Engineers	If mapping of the washes on site determine that waters of the U.S. are present, a permit will be required from the U.S. Army Corps of Engineers
	NOI for construction phase storm water permit	Construction general permit required. A SWPPP that specifies BMPs for preventing construction pollutants from leaving the site. Approval will take about a month.
	California Regional Water Quality Control Board (CRWQCB) Section 401 Permit	Required if Section 404 permit (above) applies.
	CRWQCB NPDES and SWPPP	Industrial General permit required for operations phase. A separate SWPPP will be required that outlines the monitoring and reporting plan and BMPs for the solar plant.
	Well Drilling Permit	California Department of Water Resources, Southern District permit is required for drilling water wells
Health and Safety	Trenching and excavation permit	Submit completed permit application to any OSHA district of field office prior to commencing construction
	Permit to erect a fixed tower crane	Submit completed permit application to any Cal-OSHA district of field office 24 hours prior to commencing activity

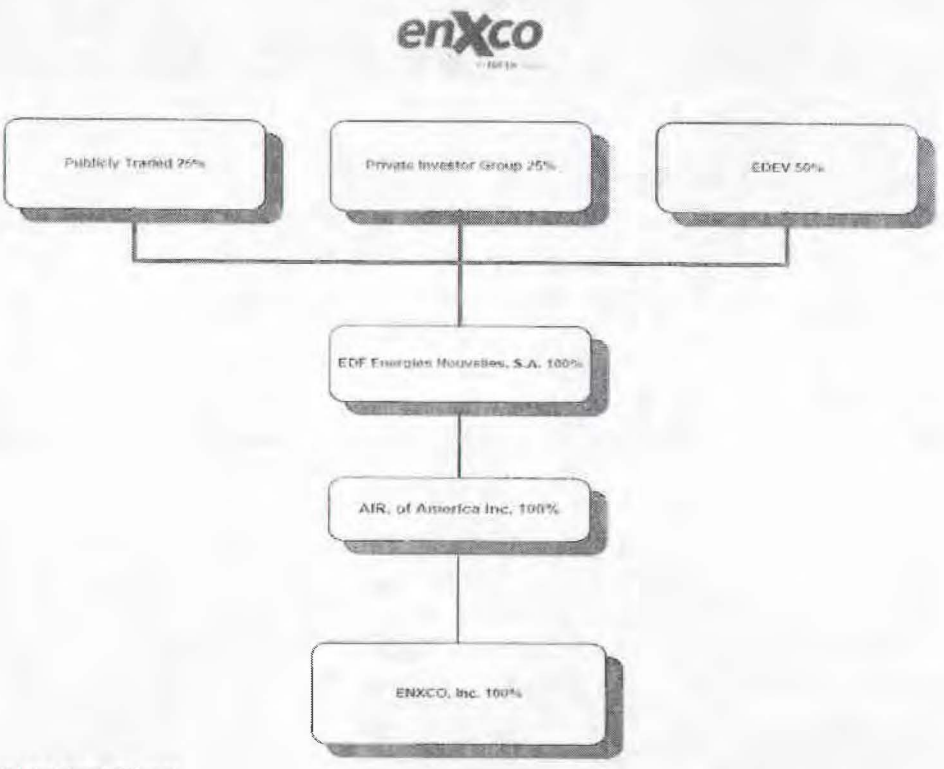
1.3.1 Status of Permits

All permits are in preliminary stages. The only permit filed with any agency at this time is the Standard Form 299, filed with the BLM. At this time, required permits have been identified, and a timeline for acquiring permits has been established. The following permits will be applied for in the next year:

- BLM permit for biological surveys
- BLM permit for cultural surveys
- Well drilling permit to test for water availability

enXco

1.4 Financial and Technical Capability of Applicant



1.4.1 About enXco, EDF EN and the EdF Group

enXco undertakes four core activities in the renewable energy industry: development; ownership, operations and maintenance; and asset management services for renewable energy projects throughout the United States. With more than two decades of experience in the wind industry, enXco has a rich history in renewable energy as one of the oldest full service wind energy companies in the United States, and has emerged as an industry leader in project development, finance, construction and operations and maintenance. In mid 2007 enXco, expanded into solar CSP development. As part of this transition enXco has completed construction of 4500 kW of Solar PV installations as of Dec 2008.

Since 1999 enXco has developed and installed 1,500 MW of renewable generation capacity and operates and maintains over 4000 wind turbine generators or more than 1,300 MW. enXco is a wholly owned affiliate of EDF Energies Nouvelles (formerly SIIF Energies), a 50%-owned subsidiary of the EDF Group. In mid-2007 enXco expanded into Solar development where it has aggressively been entering into the Utility and Distributed Solar PV market places.

The Southwest Region of enXco is proud to have completed construction of its most recent project, a 150 MW wind project in Solano County, CA in December 2008. enXco was the first renewable energy company to complete financing of any wind project in the United States during the financial crisis in Q3-Q4 2008, a testament to the financial strength of enXco and our parent company.

Founded in 1990, EDF Energies Nouvelles (EDF EN) is a world-class player in the green electricity generation market. With a presence in 9 European countries and in the United States, EDF EN operates in four renewable energy segments (wind, hydro, biomass and solar). Non-US gross installed capacity amounted to 1,400 MW (of which 900MW is installed for ownership). With its unique profile as an integrated operator, EDF EN's presence spans the entire value chain, from development and construction through to generation and operations & maintenance. The Group also pursues the development and sale of structured assets, which consists primarily in selling renewable energy generating assets to individuals or to energy services companies. EDF EN is a 50%-owned subsidiary of the EDF group. Please see the following figure for an organizational structural chart of enXco, EDF EN and the EDF Group.

enXco Organizational Chart

1.4.2 Financial Capability

As mentioned above enXco is fully owned by EDF EN. That relationship gives enXco the significant advantage of bringing to bear the financial backing of its parent company. The result is that enXco is able to secure deals with renewable energies' most exclusive players, and enjoys a financial credibility that is envied throughout the development community.

enXco and EdF Energies Nouvelles have extensive experience with renewable energy project financing. enXco and its affiliates are highly active in the capital markets, maintaining significant relationships in both the debt and equity markets for wind energy. Since 2000, enXco has financed more than $550 million of wind projects via a variety of debt and equity structures, and enXco expects to finance nearly $1 billion in additional wind projects in 2008/2009.

enXco's recent financial closing during the financial crisis in Q4 2008 of the 150 MW wind project in Solano County, CA is a testament to the financial strength and capability of enXco.

1.4.3 Finance structure

enXco will provide or secure all necessary capital through the development, construction, and operation phases of the proposed project. enXco has direct experience with a variety of financing structures, including strategic flips, all-equity with and without back-leverage, Pay-As-You-Go, cash and ITC leveraged, and pure cash-leveraged. The appropriate finance structure will be selected upon final negotiation of PPA terms, and long-term capital, both debt and equity as needed, will be arranged by enXco. Preliminary financing work for the Project will begin with the indication from the utility that it intends to execute a definitive PPA with enXco. The formal financing process will be undertaken immediately upon the execution of a power

purchase agreement, giving ample time to complete arrangements on or before the commencement of construction.

1.4.4 enXco's Solar Experience

For more than 20 years EDF EN has been involved in the development of solar thermal and solar electricity projects throughout a majority of Europe. This experience has ranged from residential to small scale distributed electricity to utility size projects.

In addition to an impressive solar profile of installed capacity, EDF EN has consistently sought partnerships that would allow the EDF EN group to grow within regional markets. By uniting developers, manufacturers, contractors and service organizations EDF EN has been able to secure market footholds throughout Europe. In order to further strengthen its presence in solar electricity generation EDF EN established a shareholding in several companies, namely Fotosolar in Spain, RETD in Greece and Photon Power Technologies in France.

Reinforcing enXco's commitment to all viable solar technologies, in July 2007 EDF EN entered into a global supply agreement for 230MW of thin film PV modules over five years. The order covers 230 MW in modules deliverable progressively between mid-2007 and year-end 2011. The First Solar purchase will enable EDF EN to secure part of its construction program of photovoltaic plants both for its own use and for third parties in Europe and the United States. Agreements with other emerging solar panel providers have followed suit, including Nanosolar, Unisolar, and Solar Fun.

enXco completed construction of the 1 MWp Sacramento Soleil project in mid-2008, and EDF EN completed a 7 MWp facility in Narbonne, France in December, 2008. The electricity generated by the Sacramento Soleil facility is under contract with the Sacramento Municipal Utility District (SMUD). EDF EN group, including enXco, has a portfolio of over 1,500 MWp currently under development in France, Spain, Italy, Greece, the United States and Canada.

enXco leverages the vast technical experience of EDF-EN to vet the various CSP technologies that are coming to market. As the world's largest owner of nuclear plants, our parent company, EDF, understands the thermal power industry, and is prepared to make a significant investment in the solar tower market.

1.4.5 enXco's Operating and Maintenance Experience:

In 1987, enXco started providing retrofits of turbines to a young wind energy industry in the United States. This operation quickly grew into one of the largest and most respected providers of wind turbine operations and maintenance services in the world.

These "O&M" services are provided out of offices in Palm Springs, Tracy, and Tehachapi, California, and Colorado, Texas, and Iowa. Major shop facilities in Palm Springs and Tracy provide enXco with in-house capability to perform a full range of component repair.

enXco operates over 4000 wind turbines. Its extensive experience, on a wide variety of wind turbine models and vintages, gives it a unique perspective on getting the best performance out of

each project. The experience includes re-engineering and retrofitting over 1,400 wind turbines to improve reliability and performance.

Results count - and enXco's experience, coupled with proven procedures and trained and experienced personnel, gets those results.

2.0 Construction of Facilities

McCoy Soleil plans to select an EPC contractor with experience in thermal power plant station design and solar technology. The construction team will mobilize as soon as possible after project certification. Site preparation work will include site grading and storm water control. Gravel will be used for temporary roads, laydown, and work areas. Mobile trailers or similar suitable facilities (for example, modular offices) will be used as construction offices for McCoy Soleil and subcontractor personnel. Construction laydown and parking areas will be within the areas of the project site and their locations will be determined by on phase construction scope and sequences. Site access will be controlled for personnel and vehicles. A security fence will be installed around the plant site boundary, including the laydown area. Security will be maintained as required by the EPC contractor, or a suitable subcontractor to maintain public safety.

During construction, temporary utilities will be provided for the construction offices, laydown area, and the project site via existing distribution lines to the west of the site. Temporary construction power will be utility-furnished power. Area lighting will be provided and strategically located for safety and security, and targeted to minimize light pollution for area neighbors.

Communications among personnel during construction, as well as operation, will consist primarily of handheld radios. enXco is aware of Department of Defense (DOD) sensitivity to electronic spectrum use, and will communicate with and obtain confirmation from the DOD of the acceptability of frequency usage by McCoy Soleil.

The following site services will be provided by McCoy Soleil subcontractors:

- Environmental Health Safety Training
- Site Security
- Site First Aid
- Construction testing (NDE, Hydro, etc.)
- Site fire protection and extinguisher maintenance
- Furnishing and servicing of sanitary facilities
- Trash collection and disposal
- Disposal of hazardous materials and waste in accordance with local, state, and federal regulations

Construction of the generating facilities, from site preparation and grading to commercial operation, would be expected to take about 30 months. It would take about 100 man-years of construction workers' time to build the plant. The man loading will follow a bell shaped curve over the 30 months of construction and will peak at approximately 400 to 500 personnel of construction craft people, supervisory, support, and construction management personnel onsite during construction.

Typically, construction would be scheduled to occur between 5AM and 7PM on weekdays and Saturdays. Additional hours may be necessary to make up schedule deficiencies, or to complete critical construction activities (e.g. pouring of concrete at night during hot weather, working around time-critical shutdowns and constraints). During some construction periods and during the startup phase of the project, some activities would continue 24 hours per day, seven days per week.

2.1 Solar Field Design, Layout, installation, and construction

The solar field in McCoy Soleil will cover the majority of the project area, as shown in Figure 3 in the Appendix. For the number of disturbed acres, please see the table in section 1.2.3. See section 2.2 for the proposed sequence of construction.

2.1.1 Timetable for construction

Please see Figure 10 in the Appendix for a projected timetable for development and construction.

2.2 Phased Project: approach to construction and operations

The project will be constructed in one period of time, with one on-line date. However, the construction phases for the proposed project is expected to be as follows:

Site Disturbance – Within the heliostat array fields, the power block area, the permanent facilities located around the perimeter road and in the temporary construction logistics area, clearing would be performed. Vegetation would be removed with a brush rake, as necessary, in order to separate the vegetation from the soil.

Preparation – Parking areas for construction workers and laydown areas for construction materials would be prepared. Detailed information regarding the location within the solar field of the laydown and parking areas would be developed once the project is finalized. Please see the drawings in the Appendix for location of the staging area.

Access Road – Primary access to the site is discussed above. Treatment for the roads is detailed in the next section and shown in the Appendix.

Site Grading – The existing site has a slope of about 1-2%. Grading will take place to generally maintain the minor slopes of the terrain, however, cuts and fills will be made to generate uniform planes for the erection and operation of the heliostat fields. Extensive grading of the site would be limited to the power block areas, receiving towers, the diversion ditches and dikes, and the major access roads (gravel roads between power blocks, and gravel roads servicing the receiving towers from the power blocks). Materials stored temporarily in the lay down area would be stored on dunnage to protect it from ground moisture.

Foundation – All underground piping and wiring would be installed, followed by installation of the foundation for the new power blocks, solar towers, and associated structures.

Plant Construction – After final site design and prior to any soil disturbance, the Applicant would be required to finalize the Drainage, Erosion, and Sediment Control Plan / Construction SWPPP (DESCP / SWPPP). During construction, the Applicant would be required to follow the DESCP/SWPPP to prevent the offsite migration of sediment and other pollutants and to reduce the effects of runoff from the construction site. Best Management Practices (BMPs) to be used at the site would be fully addressed in the DESCP/SWPPP; the DESCP/SWPPP would include the location of BMPs to be used, installation instructions, and maintenance schedules for each BMP.

Site Stabilization – It is expected that site stabilization will include soil binders, geo-grid or the use of aggregate surfacing to allow the movement of maintenance vehicles and mirror wash water trucks to travel within the solar array. The predominant surface soil is expected to be relatively well graded soil, sand, and gravel, and undisturbed existing soil. The power block area would be graded with moderate slopes to direct runoff into the salt containment basin. This will allow the storm water to infiltrate locally. The south western area of the site will contain the detention pond that will provide an area to allow sediment to be deposited and on site storm water to be controlled.

Demobilization – All temporary construction facilities would be removed and recontoured and revegetated as necessary. The project construction team or contractor would mobilize and develop temporary construction facilities and laydown areas adjacent to the power block. Once a final design has been established, the contractor would prepare site maps showing the construction project in detail. Temporary facilities would include:

- Approximately 4 single-wide full-length trailer offices or equivalent
- Chemical toilets
- Parking for approximately 500 vehicles
- Approximately 15 tool sheds/containers
- Equipment parking for approximately 20 pieces of construction equipment
- Construction material laydown area
- Solar field equipment laydown area
- Batch plant
- Rock processing equipment
- Construction Access and Material/Equipment Delivery

2.3 Access and Transportation System, component delivery, and worker access

The access to the project site would be through the existing Arlington Mine Road, and an existing north-south dirt road. The existing dirt road would need to be widened and improved to accommodate the heavy machinery required to construct McCoy Soleil.

Access roads within the project site would include at least three 18-foot wide roads and one 60-foot wide road radiating from the central tower, as seen in Figure 3. Final service road alignments would be dependent upon the final results of the environmental report documenting the results of field investigations, including topography and any other site-specific details to be incorporated into the final design. All standard engineering practices are incorporated into the road design and all applicable engineering designs will be applied to minimize soil erosion as

caused by normal seasonal precipitation. The project access will use as much of the existing road structure as feasibly possible.

Most existing roads will require upgrades to accommodate the load size associated with the equipment required for on site construction and installation of the power block. The modifications will include the reduction of grade or steepness and increase the width to approximately 36 feet, as well as increasing the turning radius of existing curves to allow for equipment hauling.

Each heliostat must be accessed by a small crane and other required heavy equipment during the construction and operation and maintenance phases. The road design will minimize the total amount of disturbed area as well as reduce visual impact. These local project access roads will remain after the project construction is complete for ongoing site activities required by maintenance activities. Again, all standard engineering practices will be incorporated into the design to minimize erosion due to normal seasonal precipitation and maintain the sheet flow across the site. For standard road treatments, please see Figure 7.

2.4 Construction Work force numbers, vehicles, equipment, timeframes

The on-site workforce will consist of laborers, craftsmen, supervisory personnel, supply personnel, and construction management personnel. The on-site workforce is expected to reach its peak of approximately 500 individuals. There will be an average workforce of approximately 250 construction craft people, supervisory, support, and construction management personnel on site during construction.

Construction will generally occur between 7 a.m. and 7 p.m., Monday through Friday. Additional hours may be necessary to correct McCoy Soleil schedule deficiencies or to complete critical construction activities. For instance, during hot weather, it may be necessary to start work earlier to avoid pouring concrete during high ambient temperatures or to avoid heat stroke. During the startup phase of the project, some activities might be performed over the weekend.

Table 4 – Construction Process

Construction Phase	Description	Approximate Number and Type of Construction Equipment and Vehicles
Rough Grading	Grubbing, clearing and bulk grading,	Approximately 20 Scrapers, 5 Compactors, 4 Graders, 2 Loaders, 4 Dozers, 10 Water Trucks, 6 Water Pulls
Finish Grading	Final grading to finish grade	Approximately 4 Scrapers, 8 Graders, 1 Dozer, 4 Water Trucks
Roads, Foundations, Flatwork and Site Utilities	Construction of roads, excavation and construction of foundations for heliostats	Approximately 20 to 40 pieces of equipment will be present at any one time, including concrete trucks, concrete pumps, backhoes, excavators, loaders, graders, foundation drills, paving machines, drum rollers, fork lifts,

		tractors, dump trucks, small cranes and additional support vehicles.
Heliostat Assembly and Deployment	Field assembly of heliostats in temporary shop buildings constructed at the site. Installation of assemblies on cast-in-place piers, or other foundations.	Approximately 8 to 10 crews, each with one or two pieces of equipment including small cranes, forklifts, welding machines, trucks and tractors.
Power Block Construction	Construction of foundations, structural frames and buildings, installation of utilities and equipment, including the STG, condenser, pumps, buildings, ACC cooling structure, TES tanks, and central receiver tower.	An average of 12 to 18 pieces of equipment will be utilized for power block construction over the duration of the project, with more equipment being utilized during the early stages of foundation construction and frame erection. Equipment will include backhoes, excavators, foundation drills, concrete trucks, concrete pumps, forklifts, boom trucks, lifts, cranes, welders, trucks and other support vehicles.
Liquid Salt Preparation	Melting of the delivered dry salt product	Temporary propane fired auxiliary boiler, forklifts, loaders, and trucks.

2.5 Site Preparation, surveying, staking

Site preparation will begin shortly after final permitting is complete for McCoy Soleil. Final surveying, to accommodate existing ROW grants, and setback requirements for the railroad to the east, transmission line, will precede any site work. Surveying will be completed by a surveyor permitted to work in Riverside County. The surveyor will stake the edges of the project area prior to erection of the security fencing.

Security fencing will be erected around the entire perimeter of the project area, with an access gate as shown in Figure 3, prior to beginning construction. Site perimeter fence will be 8 feet high and have an overall height of no more than 10 feet from the bottom of the fabric to the top barbed wire. The fence will have top rail, bottom tension wire, and three strands of barbed wire mounted on 45 degree extension arms. Posts will be set in concrete.

Controlled access gates will be located at the entrance to the facility. Site gates will be swing or rolling type access gates. Access through the main gate will require an electronic swipe card, preventing unaccompanied visitors from accessing the facility or construction area. All visitors will be logged in and out of the facility during normal business hours. Visitors and non-employees will be allowed entry only with approval from a staff member of the facility. Visitors will be issued passes that are worn during their visit and returned to the main office when leaving. The facility will be staffed 24 hours/day and 7 days per week to maintain security. Even when the facility is not generating electricity, personnel will be present for maintenance and site security. See sheet CIV-101 for location of the security fence line and operations area, and sheet CIV-110 for details.

enXco

2.6 Site Preparation, vegetation removal and treatment

Excavation will require the removal of all vegetation from the areas to either be excavated (cut) or filled, which include the powerblock and tower, access roads, laydown, parking and O&M facilities. Vegetation under 18" may be able to be maintained within the solar field. At a minimum, all vegetation between every other row will be cleared with a blade to reduce the risk of fire and allow construction and maintenance access. Scarifying by blade will disturb the soil to several inches and potentially allow some roots to remain to assist in soil stabilization and reduce the possibility of erosion. These scarified areas will serve as the access roads for both installation and continued maintenance and cleaning of the heliostat field. As such, they will be moderately graded to allow regular access with a pick-up truck-mounted tanker for washing. Continued weed management in cleared areas would be maintained through targeted application of herbicides such as Roundup® and/or by occasional scarification. Additional soil disturbance by regular operations of the plant is not expected.

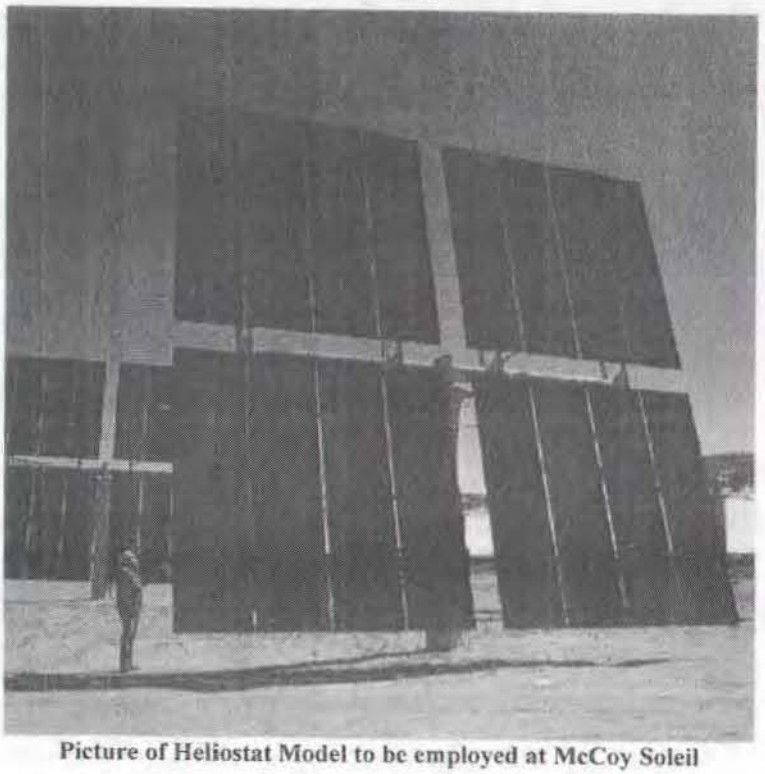
Continued weed management in cleared areas would be maintained through targeted application of herbicides such as Roundup® and/or by occasional scarification. Additional soil disturbance by regular operations of the plant is not expected.

2.7 Site Clearing, Grading and excavation

Excavation will require the removal of all vegetation from the areas to either be excavated (cut) or filled. Grading activities will be completed with traditional earthmoving equipment including but not limited to bull dozers, scrapers, motor graders, excavators, water trucks, water wagons, loaders, and compactors. The majority of the efforts to grade the site will be completed within the first year of construction activities. Early grading will be completed in the area of the roads (to provide access), the laydown area (to provide an early location for storage), and in the power block (to provide an early start to the power block construction activities). Completion of the earthwork within the solar field will follow immediately after or during the early grading activities in order to allow construction of the solar field heliostats. Minor grading will be ongoing in the form of excavation and backfill for foundations, underground piping, duct bank and other miscellaneous facilities for the duration of construction.

Materials suitable for compaction will be stored in stockpiles at designated locations using proper erosion prevention methods. Materials unsuitable for compaction, such as debris and large rocks, will be disposed of at an acceptable location. Top soil will be stockpiled for re-use in landscaped areas. Any contaminated materials encountered during excavation will be disposed of in accordance with applicable laws, ordinances, regulations, and standards.

Compaction will be performed in uniform layers of specified thickness. Materials in each layer will be properly moistened to facilitate compaction to the specified density. To verify compaction, representative density and moisture content tests will be performed in the field during compaction. Structural fill material supporting foundations, roads, parking areas, etc. will be compacted. Prior to placing fill materials, subgrades will be examined for loose or soft areas and further excavated as necessary. Details on the tower foundation will follow shortly after proper geotechnical studies are performed on the site.



Extensive grading of the site will be limited to the power block area including the receiver tower, the drainage channels and berms, storm water collection ponds, and the major access roads. Within the heliostat array fields, grading cuts and fills will be limited, only as required to obtain smooth graded planes. Vegetation within the solar fields will be cut or removed to the soil surface to reduce the fire risk, as needed.

Existing slopes in the area of the project vary from flat to 1 % from the north to south direction. The watershed area primarily comprises the Little Maria Mountains to the north and the Big Maria Mountains to the northeast. The dry washes passing through the proposed site are tributary to the McCoy Wash. Most of the McCoy Mountain runoff will pass southwest of the solar field in the McCoy Wash. The solar field will ideally maintain a positive terrain slope of approximately 1.0 %. Detention will be provided in the southern section of the solar field allowing temporary flooding during the design rain event. Detained storm water will be released at pre-developed flow rates to follow historic drainage patterns, primarily McCoy wash and the minor wash to the east.

Detailed grading of the solar fields will be designed to minimize net import or export of fill and to minimize the total disturbed area.

2.8 Solar array assembly and construction

The solar field at McCoy Soleil will consist of a field of approximately 8500 heliostats. Each dual-axis tracking heliostat will be set in a foundation of concrete 15 feet tall and 36 to 42 inches around. That foundation will support a dual axis tracking motor which will focus the sun's energy on the top of the tower by pointing a 120m^2 mirrored surface. Please see below for a picture of a typical heliostat.

Picture of Heliostat Model to be employed at McCoy Soleil

Approximately 8500 of these heliostats will be sited around the base of the tower. This sort of solar field technology is unique in that the siting of these heliostats is more flexible than the solar fields of other CSP technologies. By being somewhat modular in nature we will have a better ability to avoid washes, hills, mounds and other micro-topography than that of a typical trough plant. Thus a solar tower would require a fraction of the grading necessary for a trough plant, and will thus maintain the integrity of the soil surface. On completely flat surface, with no natural micro-topography the 8500 heliostats would be arranged as can be seen in the following figure. Though enXco anticipates it will have to site a portion of heliostats do to micro-topography, it will endeavor to keep the solar field as tight as possible so to limit the total area affected by the solar field.

The heliostat assemblies will be mounted on steel or concrete foundations. The geotechnical information and the potential pile test program will provide the information necessary to determine the most cost effective foundation. The most likely foundation will be a reinforced concrete pier foundation that is cast in a drilled hole. Alternate foundations could be concrete or steel piles.

The heliostats consist of glass mirror modules, structural support components, motor drives, a heliostat controller and a foundation. There are a total of approximately 17,350 heliostats each with a mirror surface area of approximately 670 ft^2 (62.4m^2). The total mirror surface area for each plant is approximately 12,000,000 sf^2 (1,081,200m^2). The support structure consists of a steel frame backing to support the mirror modules and a steel tubular post for supporting the heliostat in the ground. Finally, the heliostat assemblies will be mounted on steel or concrete foundations. The geotechnical information and the potential pile test program will provide the

information necessary to determine the most cost effective foundation. The most likely foundation will be a reinforced concrete pier foundation that is cast in a drilled hole. Alternate foundations could be traditional concrete mat foundations, concrete piles, or steel piles.

The Heliostat Array Controller (HAC) includes all hardware and software to control the Collector Field and consists of the Heliostat Control Software (HCS) and Beam Characterization System (BCS). The HCS actively controls the pointing of each heliostat to ensure that the heliostats image is properly positioned to ensure proper flux on the receiver. The actual pointing varies by the time of year and day, ambient temperature and mode of operation. Modes of operation include start-up, normal operation, shut-down and a number of off-nominal conditions (e.g., loss of heliostat power). The BCS automatically calibrates each individual heliostat using a BCS target located on the tower. There are sixteen (16) BCS targets on the tower and heliostat calibration is integrated into normal plant operations on a daily basis. Control/power wire for the HCS will be installed underground throughout the solar field.

2.9 Power Plant Construction

At the center of the heliostat field is the power block with the central receiver tower, steam turbine generator, cooling systems, salt storage tanks, and electrical facilities. The tower will be approximately 600 ft tall, with the solar receiver taking up the top 60 ft. The tower will be made predominantly of slipform concrete, with the solar receiver sitting on top and a few other ancillary elements like walkways and cranes to help service the receiver during scheduled maintenance. The receiver is made of a several panels and a multitude of thin-walled pipes through which the molten salt flows. To the right is an indicative picture of the solar receiver to be used at McCoy Soleil. Please see Figure 4 for a drawing of the central power block, and Figure 8 for a drawing of the tower in the Appendix.

Solar Receiver

The first phase of power block construction would consist of foundation work and underground mechanical work. Foundation construction would involve excavation, form, and rebar work preceding a number of concrete pours. The specific equipment in-use is more variable as the individual foundations and components are erected. The central receiver tower will be constructed of reinforced concrete using a slip-form process. Underground pipe work would require trenching, onsite welding, backfill, and compaction. When the foundations have cured adequately, major equipment and aboveground piping can be installed. During this phase of construction the steam turbine generator (STG), water treatment system, air-cooled condenser, generator step-up transformer, auxiliary transformers, and other

ancillary equipment would be set on their corresponding foundations. Major equipment components would be installed and pump, turbine, and fan alignments would be performed.

With the equipment set on their foundations, aboveground piping and electrical activities can be completed. Piping and electrical cable would be terminated at equipment interfaces. High-voltage bus duct will be installed between the STG and generator step-up transformer. The final construction activities will include switchyard installation, site paving, and control system installation and programming. Once systems are installed and complete, commissioning will begin. Commissioning activities include operating pumps and motors, opening and closing valves, cleaning pipe systems by water flushes and air blows, and energizing equipment. Equipment is operated isolated from other systems to ensure proper operation. Once systems are verified the plant as a whole is operated to ensure all systems function correctly. During start-up, all systems are operated and steam is generated to perform steam blows, which are used to clean the steam piping. Once the steam lines are cleaned steam is introduced into the steam turbine. Once the plant is running reliably, testing is performed to ensure emissions and performance guarantees are met.

Concrete, mechanical, and electrical works would be performed over a period of months, with the aid of graders, rollers, front loaders, dump trucks, trenching machines, concrete mixer and pump trucks, cranes, and pick-ups. Approximately 60,000 cubic yards of concrete will be used to construct the power block and heliostat fields.

Some of the above areas may impinge on areas intended for the later stages of solar field erection. As solar field erection nears completion in the power block area, temporary construction mobilization areas would be reduced as required. Solar field equipment and material laydown areas would be rotated through the site on the quadrants currently being assembled.

Miscellaneous, non-vehicle, motorized equipment will also be used over the length of the job, such as welding machines and compressors.

The HTF system hot and cold tanks would be first preheated to help prevent against thermal shock to the tank and foundation. The cold tank, for example, will be maintained at the preheat temperature for at least a week or longer before fluid salt is pumped into the tank. It is expected to take approximately 2 to 3 months to melt and load the complete volume of salt. An external recirculation loop with a heater will then raise the temperature and maintain it at 550° F.

HTF processing will take place in an area surrounded by temporary earth dikes to prevent potential migration of the salt from the processing area with storm water. Incidental spills of salt would be cleaned up. In the event of inclement weather conditions, stockpiles and storage sacks of salt would be covered with plastic to prevent potential contact with storm water.

2.10 Gravel, aggregate, concrete needs and sources

Gravel will be required for the surfacing of roads, parking areas, and for use in concrete. A geotechnical investigation will provide information necessary to determine if adequate aggregate

can be generated on site. Based on visual observations of the site, it appears that gravel sources within the grading area of the site are available. If on site gravel/sand is available (in quantity and quality), a portable rock processing operation will be used to generate select aggregate from on site sources. The rock processing operation will include screens, crushers, and conveyors to generate material that meets the project requirements.

If adequate material is not available on site, gravel and aggregate will be purchased from commercial sources in Blythe, CA or Parker, AZ and transported to the project.

The construction of the project will require a large quantity of concrete delivered to the site over the duration of the construction timeframe. Two options exist to serve the project needs. First, a portable concrete batch plant can be mobilized and used to batch the concrete necessary for the project. The second option is to obtain concrete from a commercial source in either Blythe, CA or Parker, AZ.

2.11 Electrical Construction Activities

The project will be connected to the existing and proposed Southern California Edison (SCE) transmission system at the Midpoint substation located 14 miles away. The interconnection map in the Appendix shows the proposed interconnection route. enXco is expecting a System Impact Study for this interconnection from the CAISO in the spring of 2010.

Construction activities for the transmission and electrical facilities will commence after the construction of the solar field. Construction will take place continuously along the length of the gen-tie route and require approximately 40 workers. Please see Figure 10 in the Appendix for a detailed preliminary timeline for development and construction

Detailed plans for transmission line and electrical interconnection facilities will continue to be developed during the application process and will likely include the following activities:

- Marshalling Yards: these areas will involve project laydown, parking, and areas for trailers
- Road Building: access roads will be required for each tower. They will be sited to avoid sensitive habitat identified in the detailed environmental surveys
- Pole Erection: poles will be assembled on site, with conductors, insulators and other hardware
- Conductor Pulling: There will be as many as 40 pull sites over the 14 mile interconnection. Pull sites will be limited to existing roads and new access roads where possible. Conductors will be pulled, sagged and connected permanently to the insulators.
- Communication System: Overhead fiber optic cable will be installed using the same pulling sites as for the conductors.

2.12 Aviation Lighting

enXco anticipates no aviation restrictions for this solar plant. Structures will all be less than 10 feet in height, except for transmission towers, and the O&M building, which will both be lower than the height which requires aviation lighting. Since existing transmission facilities are in the

area and along the ROW that enXco proposes to use to reach the substation, the project is anticipated to produce no significant aviation impact. If required, any additional transmission towers will employ the necessary aviation safety lighting.

2.13 Site Stabilization, protection, and reclamation practices

enXco will restore all temporarily disturbed areas to their preconstruction conditions, as required by the BLM. These include temporary construction areas, access roads, as well as transmission access areas. These areas would be revegetated to restore them to preexisting conditions. Where disturbance will occur due to construction, topsoil will be stockpiled, and certain plants that are able to be transplanted will be preserved for the revegetation.

As a part of soil stabilization and dust mitigation, it is expected that road treatments will include soil binders, geo-grid, or the use of aggregate surfacing to allow the movement of maintenance vehicles and heliostat wash water trucks to travel within the solar array. Other procedures for site stabilization are discussed in sections 2.6 and 2.7.

2.13.1 Site Closure and Reclamation

The expected operational lifetime of McCoy Soleil is 30 years, however depending on economic or other circumstances the real life of the project could be longer or shorter.

In case of a temporary closure of the facilities, the BLM, and any other responsible agencies will be notified. If temporary closure involves the threat or actual release of hazardous substances, procedures will be implemented from the Hazardous Materials Business Plan, as developed for the project. Procedures will include, but not be limited to, the following:

- Practices to control any release of hazardous materials;
- Applicable notifications of responsible agencies and the public;
- Emergency response procedures;

When permanent closure is appropriate, a decommissioning plan will be developed and submitted to the BLM for review and approval. Procedures will be designed to ensure public health and safety, environmental protection and compliance with all applicable LORS. Closure may range from temporary "mothballing" to complete removal of equipment and restoration of the land to BLM approved specifications. The procedures for decommissioning are designed to ensure public health and safety, environmental protection, and compliance with applicable regulations. It is assumed that decommissioning would begin 30-50 years after commercial operation date of the solar plant.

Decommissioning will generally include the following goals:

- Remove above ground structures unless converted to other uses
- Restore the lines and grades in the disturbed area to match the natural gradients of the site, and;
- Re-establish native vegetation in the disturbed areas
- Conform with applicable LORS and local/regional plans
- Secure funding decommissioning and restoration

The proposed strategy to achieve the above goals could include the following:

- Analyze alternatives other than full restoration of the site (for instance, removal of old facilities and upgrading to newer solar technology)
- Use industry standard demolition means and methods to decrease personnel and environmental safety exposures by minimizing time and keeping personnel from close proximity to actual demolition activities to the extent practical;
- Plan components of decommissioning to ensure personnel and environmental safety are maintained while efficiently completing the work.
- Provide for recycling the components of the plant: metal, heliostats, concrete, etc, and proper disposal of all other materials.
- Remove all residual materials and chemicals from the site prior to demolition for reuse at other facilities or disposal at licensed facilities.
- Demolition of below-ground facilities to a depth required for restoration of the native habitat.
- Soils clean-up, if needed, particularly at locations where hazardous materials were used or stored to ensure that clean closure is achieved.
- Recontouring of lines and grades to match the natural gradient and restore natural water flow to the site
- Revegetation with native plants

The first stage of dismantling the site consists of removal and demolition of above-ground structures. The second stage consists of dismantling and removing concrete structures so that no concrete remains within 3 feet of final grade as appropriate. The third stage involves removal of underground utilities within 3 feet of final grade. The fourth stage consists of excavation and removal of soils to return the disturbed areas to near the original condition and to a natural gradient while disturbing as little additional areas as is practicable.

3.1 Transmission System Interconnect

3.1.1 Existing and proposed Transmission system

The existing transmission system in the area consists of a number of substations and lines operated by Southern California Edison (SCE). The existing Devers Palo Verde transmission line runs parallel to, and on the southern side of Interstate Highway 10. In addition, 161kV transmission lines run just south of the site from the Kaiser Mine and DWP pumping station to the Blythe Energy center. SCE will be constructing the Devers Palo Verde 2 transmission line from the proposed Midpoint substation to Devers.

Proposed transmission lines are therefore going to be very limited. McCoy Soleil will connect to the Southern California Edison (SCE) high voltage lines either at the proposed Desert Center substation, or as a line tap on the 230 kV DVP2, depending on results of the System Impact Study. enXco expects results of the transmission studies in approximately Q1 2010. Final path will be subject to results of the Facility Study by Southern California Edison (SCE), final detailed designs, and the secured route easement. Detailed transmission drawings will be provided soon after these studies are complete and before publication of the EIS. enXco will submit a revised form-299 that includes the proposed transmission line ROW for interconnection.

Please see drawings in the Appendix for location of existing and proposed transmission lines.

3.1.2 Ancillary facilities and substations

Additional structures necessary for the McCoy Soleil plant will be located away from the tower in order to maximize the output of the solar field. These structures would include, a systems control building, an operations and maintenance building, access roads, parking, security fencing, and other minor structures. An operations, maintenance and control center building of up to approximately 3600 square feet (approximately 60 feet x 60 feet) is required for the purpose of housing the service technicians and tools, maintenance supplies, spare parts, and the electronic control and communication systems. The building is equipped with a bathroom facility for sanitary use by technicians and/or security personnel remaining on site for the duration of the project. A parking area would be required to accommodate approximately 50 full-time employees as well as visitors. Please see the Appendix for a view of the location of the ancillary structures in comparison to the solar field and tower. The ancillary structures will be located near the project entrance as shown in the Appendix.

3.1.3 Status of Power Purchase Agreements

enXco is currently in discussions with two large utilities interested in purchasing power from McCoy Soleil. Our executives have met with the utilities several times each in the past months, and we will be submitting this project for consideration in the 2009 RFP for renewable energy at both utilities. It is enXco's belief that some of the PPAs signed to date will not be able to perform and utilities will be short of their requirements for the 20% RPS by 2010 (2012 with flexible compliance). Our strategy for wind is to develop a quality project and the electricity buyer will follow. We plan to execute the same strategy for our CSP projects.

3.1.4 Status of Interconnect Agreement

enXco expects a System Impact Study from CAISO to be complete in the first quarter of 2010. Information from the SIS will inform the economics of the project and the specific interconnection point, as well as the date of transmission line readiness.

3.1.5 General Design and Construction Standards

McCoy Soleil will likely connect to the SCE line by construction of a single-circuit three-phase 115kV or 230 kV transmission line that would interconnect to the conceptual Midpoint substation. Foundations for the transmission line structures consist of single concrete piers reinforced as necessary to withstand design loads. The poles are approximately 80 feet in height with a span length expected to average approximately 500 feet. As identified in the Appendix, the interconnection route is designed to follow major roads, railroads, and other ROW to minimize impact of further road building. Service roads will be required, if they do not already exist, to access the interconnection line. Final path will be subject to results of the Facility Study by the California ISO, final detailed designs, and the secured route easement.

3.2 Gas Supply Systems

As described above, McCoy Soleil will not require any gas supply.

3.3 Other Related Systems

3.3.1 Communications system requirements

Communication between various components of the plant will be via hard-wired cables. Trenching will be required along the rows of heliostats to connect the solar field to the O&M facilities. Trenches will be 4-feet wide, by 4-feet deep so that final conduit and wiring is at least 3-feet below the final surface. Communication wires will be installed alongside the electrical system wires. Please see drawings in the Appendix for proposed locations of trenching.

The major communication system on site would be the SCADA (Supervisory Control and Data Acquisition) system. The SCADA system is composed of industrial PLC (Programmable Logic Controllers) hardware and software, field instrumentation, meteorological stations, and communications devices designed for site monitoring, control and historical trending of the solar plant.

All data collected from the field would be transmitted to the site Control Room via a fiber or copper communications infrastructure, sited alongside the electrical lines running from the heliostats to the powerblock. The control room will also contain a router for the point of connection to a T1 line or equivalent as well as phone lines for communication to the outside. These will be brought to the site alongside the gen-tie to the transmission system. If communication lines are not available near the site, then microwave communications will be installed.

Communication between employees during both construction and operations phases will be through handheld radios.

4.0 Operations and Maintenance

As of December 2008, enXco operates and maintains over 4,129MW of renewable energy, and employs over 300 renewable energy technicians in the United States. enXco believes that experience counts when it comes to executing development projects and operating those projects once complete.

enXco brings experienced project management skills in order to execute the McCoy Soleil Solar Energy Project. enXco's management teams have executed well in excess of 5,000 MW of power projects including natural gas fired projects, solid fuel projects, wind energy projects and other alternate fuel projects. This experience includes all development, construction, financing and operational aspect of the project. The project management tasks associated with the execution of the project include:

- Land related issues and local approvals
- Environmental Permitting
- FAA approvals
- Water supply
- Public outreach and communications
- Interconnection activities
- Equipment supply and evaluation

- Balance of plant systems and design
- Contractor assessment and selection
- Transportation
- Financing related activities
- Construction management
- Operations and asset management

enXco intends to establish independent operators with experience in operating and maintaining power facilities to operate and maintain the plant following the achievement of commercial. enXco does not expect to select an operator until construction of the plant has commenced. Plant personnel will begin being brought on-board commencing 12 months prior to the scheduled start of commercial operations (up to the total numbers included in the O&M Plan).

4.1 Operation and facility maintenance needs

It is assumed that the plant will commence commercial operations in late 2013.

The plant is assumed to operate at full load, in accordance with the allowable dispatch instructions from the utility.

The plant's performance monitoring system and processes will be updated as required to reflect initial plant operating data to best determine plant operational efficiency and cost effectiveness. Examples of these parameters are:

- Capacity
- Energy Generation
- Receiver and steam turbine performance
- Plant makeup water requirements
- Solar Heat Collected
- Molten Salt Temperatures

Mock emergency exercises will be conducted periodically in cooperation with the local fire and police departments in order to test Emergency Response Plan preparedness and to drill the plant employees in the proper execution of emergency roles and tasks.

4.1.1 Operation Plan

This plan provides the overview for the operations and maintenance of the McCoy Soleil Project (the "plant") for the first twelve (12) months of commercial operation. This plan provides basic assumptions and discussion of operations and maintenance areas and gives a short overview of the other programs used to meet the Owner and Operator objectives.

The Operating Budget provides, on a monthly basis, details for:

- Operations, repairs, and expected improvements.
- Routine maintenance.
- Expected purchases (including capital expenditures and equipment acquisitions).
- Personnel plan.

- Administrative and support activities taken in support of the plant.
- Additional related aspects.

The Operator will contract specific maintenance tasks or will perform them by the plant staff as appropriate and most cost-effective manner.

The Operator will operate and maintain the plant in accordance with approved procedures to comply with the issued Environmental Permits and appropriate government laws.

The Operator will operate the plant and associated systems to ensure that the emission limitations for air and waste water discharge contained in the plant permits are met. In addition, the Operator will ensure that all hazardous waste on the site will be stored and disposed of properly. All environmental issues and associated permits will be the subject of continuing training and management emphasis. Willful violations of environmental laws could result in employee termination for such a serious offense. At least annually, an internal assessment of environmental protection compliance will be made.

4.1.2 Maintenance Program

The Maintenance Program is conducted in accordance with the maintenance manual, vendor technical manuals, and good engineering practices. Subject to scheduled overhauls, the nominal design life for the major components of the plant is 30 years. This program consists of:

- Routine Preventive Maintenance (including "Operator checks") – normally conducted by the plant O&M staff, supported by outside contractors as required for some aspects of the predictive maintenance program (e.g., oil analyses).

- Corrective Maintenance – normally conducted by the plant O&M staff, supported as necessary by outside contractors as required due to special equipment or expertise which is not cost-effective to maintain current on site (e.g., "code" welding) or to augment efforts to return the plant to operation as soon as possible following a forced or unscheduled outage.

The solar plant will be covered by a warranty from the respective suppliers. All warranties will be tracked and compiled with and warranty claims will be made as directed by the Owner's Representative.

The Operator will utilize a Computerized Maintenance Management Software (CMMS) package, vendor and contractor recommendations, and good engineering practices to plan and implement the component preventive maintenance program.

Scheduled Maintenance periods will be planned and coordinated with the utility in accordance with the PPA. There are no planned major equipment outages. Unscheduled corrective maintenance will be decided on a case by case basis. A projected outage maintenance schedule will be submitted separately.

Maintenance Service agreements are anticipated on the following areas, as appropriate:

- Predictive maintenance testing and analysis
- Safety valve setting, calibration and maintenance
- Testing and certification of fire protection system(s)
- Calibration services (beyond the cost-effectiveness of the plant's capability), such as:
    - high voltage protective relay calibration
    - safety relief valve calibration
    - electricity flow metering calibration
- Environmental engineering services
- Consulting engineering services
- Plant security services
- Fire protection services
- Plant janitorial services
- Trash and waste material disposal (including potentially hazardous waste)
- Individual office equipment, such as fax, copies, computers, etc.
- Employee transportation (as required)

4.2 Maintenance activities including mirror washing, roads

Periodic water washes of the heliostats to maintain efficiency at the expected levels will be conducted. This will be accomplished by spraying demineralized water from a high pressure attachment on a small 4WD heliostat-washing vehicle. The quantity of water used will be sufficient for cleaning but controlled such that minimal water runs off the mirrors and onto the ground. There will be no appreciable surface water flows from this activity. Please see a discussion of water quantities and sources required under environmental considerations in section 5.

As discussed in section 2.6, some vegetation treatment will be required to maintain the site free from noxious weeds. At a minimum, the access roads in the heliostat field will be maintained free from significant vegetation through the use of targeted spraying, occasional scarifying, or weeding to reduce fire hazard and allow access to the heliostat arrays.

Roads will be maintained to minimize fugitive dust, and prevent erosion from rain events. Additional gravel or surface treatments such as "seament" on the dirt access roads may be required. Road treatments are detailed in the drawings in the Appendix, and will be reapplied as necessary to reduce dusting of the heliostats and comply with the SWPPP and other permits.

Other maintenance that will be performed in conjunction with the routine maintenance includes but is not limited to:

- Torque electrical fittings
- Clean switch gear
- Calibrate protective relays
- Fire protection system test and annual certification
- Fuse swapping, testing ground fault detection and power quality

enXco

4.3 Operations workforce and equipment

4.3.1 Staffing

Management personnel will provide technical oversight/guidance in four critical areas: overall plant management (by the "Plant Manager"), plant operations and maintenance (by the "Operations Manager"), and human resources, accounting, and administration (by the "Administrative Assistants").

No replacement/rotations of plant personnel are projected during this period. If the need for such a rotation arises, necessary arrangements will be coordinated with the Owner on a case-by-case basis.

As appropriate, O&M personnel will be provided uniforms and proper foot wear.

The Operations staff at the plant consists of:

Operators	10
Solar Field Technicians	24
Water Technicians	2
Shutdown Technicians	6
Heliostat wash technicians	2

The operations crews will work rotating, 12-hour shifts. Vacation and sick day coverage, training, or absences for any other reasons will be provided by off-shift operators/technicians, and qualified maintenance personnel, as required.

On-going training will be provided to maintain operator qualification and certification.

4.3.2 Staff Training and Safety

On-going training will be provided to maintain operator qualification and certification.

The Operator will pursue an ongoing training program in accordance with our Training Manual. The main goal of this manual is to ensure that the O&M staff remains fully competent in the safe, reliable, and efficient operation, maintenance, and administration of the plant.

Following the construction period, final qualifications shall be completed for all plant operators. Following completion of appropriate qualifications, emphasis will be placed on our continuing training program.

The Operator will send the plant staff to formal schools and training sponsored by outside activities and vendors as appropriate to ensure that O&M personnel continue to upgrade their level of knowledge of plant systems and equipment. Formal training is included in preparation of the annual Operating Budget.

The Operator will ensure that its staff is fully trained on all health, safety and environmental issues in accordance with local and national regulations, with the following objectives:

- Maintain personnel safety – the goal is zero accidents.
- Comply with all safety and environmental regulations, policies, and laws.
- Provide meaningful feedback to improve plant procedures and manuals on a continuing basis.

Plant casualty drills will be run on a periodic basis to evaluate the casualty training program. In addition, "Table Top" drill scenarios will be conducted on a monthly basis. These drills include both plant and hazardous material casualties. The written response of each section will be reviewed and critiqued with all personnel. Mock emergency exercises will be conducted periodically in cooperation with the local fire and police departments in order to test Emergency Response Plan preparedness and to drill the plant employees in the proper execution of emergency roles and tasks.

Plant employees will be encouraged to pursue outside educational courses, as well as obtaining degrees or certifications that are job-related. The expenses for these job improvement educational pursuits will be handled on a case-by-case basis.

See section 1.2.18 for a further discussion of enXco's safety history, and the health and safety program.

4.3.3 Administrative Activities

The Administrative staff consists of an Administrative Assistant and a Clerk/Procurement person.

The Operator's Project Manager will work with the Plant Manager and Administrative staff and support staff of the Owner/Operator to continue the development and implementation of the comprehensive Administrative Program.

Budget control and reporting will be administered by the Plant Manager and Administrative staff with assistance and oversight being provided by the Owner/Operator's headquarters staff. Monthly Budget Variance reports will detail financial status with respect to the approved commercial budget. The proposed Operating Budget will be submitted separately.

Plant payroll and local implementation of Operator Human Resources policies will be administered by the Administrative staff under the guidance of the Plant Manager.

Reports will be generated and distributed daily, weekly, and monthly in accordance with the Administrative Manual. These reports will include electricity generation parameters, plant performance, fuel usage, chemical usage, environmental and permitting issues, safety issues, maintenance and outage information, and information on interaction with outside agencies.

Plant Security will be provided for by an outside contractor and/or limited to remote TV cameras. The contractor will provide security for the plant on a twenty-four hour basis.

The Warehouse will be inventoried on a semi-annual basis to verify location and quantity. Additionally, monthly audits will be performed of randomly selected items to verify not only location and quantity but also proper documentation from ordering to receiving to invoicing.

Arrangements will be established with an international freight forwarding company, to expedite parts shipping, customs brokering, and other requirements to receive parts and consumables. The effective arrangements are critical to achieving the target performance.

4.3.4 Capital Improvements

The Owner/Operator will conduct an on-going program to identify any capital improvements that will increase the plant's efficiency and effectiveness. Proposed capital improvements will be submitted as part of the on-going budget process.

4.3.5 Operations Equipment

During Operations we would maintain the following fleet of on site vehicles as follows:

i. Two Heliostat Wash Trucks,
ii. Two scissor lifts or bucket cranes to maintain heliostats
iii. One portable crane
iv. Four pick up trucks for maintenance staff.

5.0 Environmental Considerations

5.1 Air Quality

There is neither combustion nor chemical reaction to produce gaseous effluents. The plant has no emissions to the atmosphere other than condenser effluent and steam relief valve discharge from the turbine generator island.

McCoy Soleil is in the South Coast Air Quality Management District (SCAQMD) and would be responsible for meeting the rules of the air district. The SCAQMD is considered in attainment for most air contaminants; however the basin has been given non-attainment status for particulate matter less than 10 microns in size (PM_{10}). Potential impacts would be considered significant if any PM_{10} emissions could contribute to an existing violation.

The principal sources of emissions from the proposed project would occur during construction; the operation of the solar project and general maintenance activities would have a negligible impact to air quality. Construction-related emissions would include the exhaust from construction equipment (including vehicles transporting personnel, equipment, and supplies) and fugitive dust and particulate matter (PM_{10}) from grading, earth moving, and equipment/vehicles traveling on paved and unpaved roads.

Implementation of the following mitigation measures will ensure that the proposed project will not have a significant adverse impact on air quality.

enXco Development Corp. may adopt, with BLM approval, standard mitigation measures recently applied by CEC staff for power plant and linear facility construction to ensure that impacts to air quality during construction are not significant.

- All unpaved roads and disturbed areas in the project and linear construction sites shall be watered as frequently as necessary to comply with the dust mitigation objectives. No vehicle shall exceed 10 miles per hour within the construction site.
- Main construction site entrances shall be posted with visible speed limit signs.
- All construction equipment vehicle tires shall be inspected and washed as necessary to be cleaned free of dirt prior to entering paved roadways.
- All paved roads within the construction site shall be swept as needed to prevent the accumulation of dirt and debris.
- All vehicles that are used to transport solid bulk material on public roadways and that have potential to cause visible emissions shall be provided with a cover, or the materials shall be sufficiently wetted and loaded onto the trucks in a manner to provide at least one foot of freeboard.
- Wind erosion control techniques (such as water, chemical dust suppressants, and/or vegetation) shall be used on all construction areas that may be disturbed.
- All diesel-fueled engines used in the construction of the facility shall be fueled only with ultra-low sulfur diesel, which contains no more than 15 ppm sulfur.
- All construction diesel engines, which have a rating of 100 hp or more, shall meet, at a minimum, the Tier I California Emission Standards for Off-Road Compression Ignition Engines as specified in California Code of Regulations, Title 13, section 2423(b) (I) unless certified by the on-site AQCMM that such engine is not available for a particular item of equipment.

5.2 Biological Resources

In choosing the McCoy Soleil site, enXco sought to avoid the most sensitive habitats and species. For example, the site is outside of the Desert Wildlife Management Area (DWMA) for desert tortoise.

enXco's consultants have undertaken preliminary biological studies to understand the potential biological resources at the McCoy Soleil site. The consultants have significant history with BLM, and have excercised high quality in their work on past enXco wind projects.

The McCoy site is composed primarily of creosote bush scrub habitat. This habitat type is characterized by widely spaced creosote bushes (*Larrea tridentata*) and includes associates such as brittlebush (*Encelia* sp.), white bursage (*Ambrosia dumosa*), and a variety of seasonal annuals. Desert wash woodland is the second most common habitat in the area. This habitat consists mainly of drought-deciduous leguminous trees growing along ephemeral washes (Bureau of Land Management 2003b). Typical species include ironwood (*Olneya tesota*), catclaw acacia (*Accacia greggii*), and palo verde (*Cercidium* sp.). In some areas, a non-native, invasive tree or shrub called salt cedar (*Tamarisk* sp.) occurs in washes. Wildlife species richness is much higher in native desert wash woodland than in other community types in the desert, and this community is slow to recover from disturbance (Bureau of Land Management 2003b).

Based on research using available geographic information system (GIS) data sets, regional occurrence databases administered by the U.S. Fish and Wildlife Service (USFWS) and the California Department of Fish and Game (CDFG), and the California Natural Diversity Database

(CNDD), T&E species that could potentially occur at the site are limited to the desert tortoise (*Gopherus agassizii*) and the razorback sucker (*Xyrauchen texanus),* though habitat for the latter species does not appear to be present in the project area. enXco is also aware that the desert wash woodland habitat in McCoy wash is a highly sensitive and important habitat. Site selection has been careful to exclude this habitat from any impact whenever possible. enXco's consultants have met with the BLM in order to discover any additional information on biological resources that BLM might have. A more extensive survey of the site will occur during the detailed environmental work in preparation for the EIS/AFC, including tortoise protocol level surveys.

Mitigation will be necessary for the desert tortoise, if any individuals are found, or if sign of the tortoise is recorded in the protocol level surveys. If either of these conditions are present, enXco may adopt, with BLM approval, mitigation including the following standard desert tortoise measures:

- Tortoise-proof fences around the construction area,
- A detailed tortoise "clearing" and relocation plan for any tortoises discovered in the project area,
- A detailed plan to prevent impact to tortoises during construction activities
- Purchase of appropriate habitat to compensate for any habitat impacted by construction activities.
- Other mitigation may also be appropriate, and considered by enXco in partnership with the relevant agencies.

Other special status species that may occur at the site include 4 species of plants, 3 invertebrates, 6 birds, including burrowing owls and 7 mammals.

During the general habitat assessment survey, biologists would note if any burrows are present in the study area that may be suitable for burrowing owl use. The presence of existing burrows is a key component of burrowing owl habitat. If potential burrowing owl habitat is present, a protocol-level burrowing owl survey may be required. Other surveys would be required for the special plant species, and possibly for evidence of nesting by other special status birds.

Table of Special Status Species potentially present at McCoy Soleil

Common Name	Scientific Name	USFWS	CDFG	CNPS
Plants				
Abram's spurge	*Chamaesyce abramsiana*	-	-	2.2
Foxtail cactus	*Coryphantha alversonii*	-	-	4.3
Harwood's milk-vetch	*Astragalus insularis var. harwoodii*	-	-	2.2
Las Animas colubrine	*Colubrina californica*	-	-	2.3
Invertebrates				
A mellitid bee	*Melitta californica*	-	-	
California Mccoy snail	*Eremarionta rowelli mccoiana*	-	-	
Riverside cuckoo wasp	*Hedychridium argenteum*	-	-	
Fish				
Razorback sucker	*Xyrauchen texanus*	E	E	
Reptiles				
Desert tortoise	*Goperus agassizii*	T	T	
Birds				

Black-tailed gnatcatcher	*Polioptila melanura*	-	-	
Burrowing owl	*Athene cunicularia*	-	SC	
Crissal thrasher	*Toxostoma crissale*	-	SC	
Le Conte's thrasher	*Toxostoma lecontei*	-	SC	
Prairie falcon	*Falco mexicanus*	-	-	
Vermilion flycatcher	*Pyrocephalus rubinus*	-	SC	
Mammals				
American Badger	*Taxidea tasux*	-	SC	
Arizona Myotis	*Myotis occultus*	-	SC	
California leaf-nosed bat	*Macrotus californicus*	-	SC	
Cave myotis	*Myotis velifer*	-	SC	
Colorado Valley woodrat	*Neotoma albigula venusta*	-	-	
Hoary bat	*Lasiurus cinereus*	-	-	
Pallid bat	*Antrozous pallidus*	-	SC	

5.3 *Cultural Resources*

A BLM Class 1 cultural study, including preliminary search of tribes, tribal areas, and a site search at the Eastern Information Center located at the University of California, Riverside has been completed for McCoy Soleil. The Archaeological Information Center acts as a branch of the California Historic Resources Information Systems (CHRIS) established by the Office of Historic Preservation (OHP) and maintains information concerning cultural resources and associated studies recorded in Riverside County. Materials reviewed included archaeological site records, historic maps, and listing of resources on the National Register of Historic Places, the California Register of Historical Resources, California Points of Historical Interest, California Landmarks, and National Historic Landmarks. Results of the records search/literature review indicate that only one cultural resources inventory has been conducted within one mile of the proposed project area (Bureau of Land Management 1978) and that two previously identified sites (Table 1) have been recorded within the project area.

enXco's consultant also sent a letter to the Native American Heritage Commission (NAHC) notifying them of the proposed project activities. The NAHC was also asked to conduct a search of the Sacred Lands File and to make a recommendation as to whether any local Native American groups should be contacted regarding their concerns about potential impacts to cultural resources resulting from implementation of the proposed project. Results of this search have not been received at this time. They will be forwarded when they become available.

A draft of the Class 1 Cultural Study was submitted to the BLM for review and comment. Please see the Appendix for a complete copy of the Draft Class 1 Cultural study.

The records search shows that two linear cultural resources cross the eastern side of the project area. The first is P33-872, the "Halchidhoma" trail, a prehistoric foot path that connected the Blythe intaglios with trade routes to the west. This site was first recorded in 1976. Recent attempts to relocate portions of it have failed and its existence within the current project area is not certain. The second resource is P33- 12410 (CA-RIV-7045H), the Atchison, Topeka & Santa Fe Railroad. This portion of the railroad has not been evaluated for eligibility for listing to the NRHP but segments in San Bernardino County have been formally listed. It is recommended that

the area to be effected by the proposed project be intensively surveyed (Class III) for cultural resources prior any ground disturbing activities.

Before construction begins, the Project Archaeologist will conduct a worker education session for the construction crew and supervisory personnel to explain the importance of and legal basis for the protection of significant archaeological resources. Construction crews will be briefed regarding identification of suspected new sites, reporting, and preservation of existing and suspected new sites.

An Archaeological Monitor will be present at the construction sites at times when excavation (subsurface disturbance) is taking place in areas of high cultural sensitivity. These areas will be identified by the Project Archaeologist. If a new cultural resources site is discovered during construction, and determined to be significant, the Project Archaeologist will notify appropriate agencies and implement a mitigation plan in accordance with state regulations on private lands, as well as BLM regulations. The Project Archaeologist will arrange for the curation at a qualified curation facility of any archaeological materials collected during the construction monitoring and mitigation program.

5.4 Geologic Resources and Hazards

As a part of the environmental and permitting studies for the AFC preparation, McCoy Soleil will require a survey for geological hazards and unique geological features. In addition, extensive soil tests will be required in order to determine the proper preparation and engineering of solar plant foundations. A preliminary geotechnical evaluation was completed by civil engineers during a project walk-through. More detailed studies, as indicated in the development and construction timeline in the Appendix will inform final engineering

5.5 Hazardous Materials Handling

The McCoy Soleil project will be designed, constructed, operated and maintained to ensure the safe use and storage of hazardous materials. Storage, handling, and use of all chemicals will be conducted in accordance with applicable laws, ordinances, regulations and standards. Chemicals will be stored in appropriate chemical storage facilities. Bulk chemicals will be stored in storage tanks, and other chemicals will be stored in returnable delivery containers. Chemical storage and chemical feed areas will be designed to contain leaks and spills. Workers will be trained to handle hazardous wastes generated at the site.

Once construction is complete, McCoy Soleil will have minimal hazardous and non-hazardous waste at the site. The molten salt is a combination is a 60:40 ratio of Sodium Nitrate (NaNO3) and Potassium Nitrate (KNO3), in their sold form these two salts are traditionally used as elements in garden fertilizer. Since the salts are only used as a thermal working fluid and are not consumed, it is used continuously for the life of the plant without need for re-processing. Occasional spills of small quantities of salt from a leaking gasket quickly freeze and are picked up by plant staff and put into a waste receptacle. Depending upon the rules of the local jurisdiction this salt can be reused or disposed of in a landfill. At the end of the Solar Two demonstration period, the salt was solidified onsite and sold for fertilizer.

In addition to small quantities of salt which may leak, the turbine plant drains flow to an oily waste separator common to many steam plants and the waste removed by vacuum truck to a qualified facility. This fluid may contain lubricants and oils common to the turbine generator island. The quantity of this waste should be no different than for a similar steam unit of comparable size. Where possibilities exist for spills to occur from plant operations, catchment areas will be constructed to contain the spill. For example, the steam turbine will be sited on a cement pad with integrated containment that can control a possible catastrophic spill. Waste containing high metal concentrations, will be temporarily stored on site in portable tanks, and disposed of off-site by a chemical cleaning contractor in accordance with applicable regulatory requirements.

Safety showers and eyewashes will be provided adjacent to or in the area of all chemical storage and use areas. Hose connections will be provided near the chemical storage and feed areas to flush spills and leaks to the plant wastewater collection system. State approved personal protective equipment will be used by plant personnel during chemical spill containment and cleanup activities. Personnel will be properly trained in the handling of these chemicals and instructed in the procedures to follow in case of a chemical spill or accidental release. Adequate supplies of absorbent material will be stored on-site for spill cleanup.

Electric equipment insulating materials will be specified to be free of polychlorinated biphenyls (PCBs). Other possible hazardous materials will include various water treatment and cleaning chemicals.

5.6 Land Use

The Project area is currently designated by BLM as Class "L", "Limited Use" in the Northern and Eastern Colorado Management Plan (NECO). This area may be required to be amended to Class M: which will "provide for activities that require a major modification of the landscape."

A preliminary search of OHV and recreational uses in the NECO indicates that one dirt vehicle trail crosses the project area. enXco will site the solar facilities in such a way as to minimally impact the recreation abilities in the area. The open road that runs north-south through the project area, as well as the natural gas line, will remain open and accessible.

5.7 Noise

During operation, McCoy Soleil will generate some noise. Noise will be created by the steam turbine generator, and cooling towers, as well as vehicles on site. As part of the AFC process, noise level will be modeled at the nearest residential sites to determine if there is any impact. It is predicted that the impact will be less than significant.

5.8 Paleontological Resources

A preliminary literary search determined that the Project site does not contain any known fossil localities. A more detailed field survey will be conducted during preparation of the AFC.

Prior to construction enXco will retain a qualified Project Paleontologist to design and implement a mitigation program during project-related earth-moving activities. The paleontological resource mitigation program will include the preparation of mitigation and

monitoring plan for construction monitoring; emergency discovery procedures; sampling and data recovery, if needed; museum storage coordination for any specimen and data recovered; pre-construction coordination; and reporting.

Construction personnel involved with earth-moving activities will be informed by the Project Paleontologist of the possibility of encountering fossils, how to identify fossils, and proper notification procedures. This worker training will be prepared and presented by a qualified paleontologist. A construction contractor superintendent will be identified and provided with contact information for notifying the Project Paleontologist if any potential paleontological resources are encountered during construction.

Grading and excavation within old alluvium or earthmoving at depths greater than 10 feet should be monitored by a qualified paleontologist, along with older alluvium which occurs at depths less than 10 feet.

5.9 Public Health

A human health risk assessment will be conducted as part of the NEPA process to determine the impact of emissions of toxic air contaminants. The assessment is predicted to find that the project will pose an insignificant incremental cancer and non-cancer health risk.

5.10 Socioeconomics

Project construction is anticipated to have a positive impact on local economics. The city of Blythe is located nearby, providing a considerable labor pool for the project workforce. A more detailed analysis of economic impacts to the area will be undertaken for the AFC.

5.11 Soils

A drainage study will be required that can determine appropriate control structures and possible rerouting of any major washes that flow through the site. Typically, berms will be required on the up-slope side of the site to channel runoff around the collector field. Some internal contouring may also be required due to the size of the site in order to accommodate precipitation that falls within the plant boundary. Because the heliostats being employed are significantly larger than those for Solar Two, they will be able to accommodate greater variation in the slope of the land.

In areas where heavy grading is required, such as at the site of the central tower and powerblock, mitigation measures will be necessary to minimize erosion and control runoff. These measures may include local soil berms and detention areas that can contain storm water runoff during construction. Temporary erosion controls including crushed rock, silt fences and fiber rolls will be used as needed to minimize erosion in these areas. Water will also be used as a method to control dust during construction, likely sprayed from a truck twice per day during heavy grading activities. A more detailed erosion control plan will be developed during the AFC process.

5.12 Traffic and Transportation

The on-site workforce will consist of laborers, craftsmen, supervisory personnel, supply personnel, and construction management personnel. The on-site workforce is expected to reach

its peak of approximately 500 individuals. There will be an average workforce of approximately 250 construction craft people, supervisory, support, and construction management personnel on site during construction.

During construction, the number of truck loads and the tonnage delivered will be on the order of 12,000 loads totaling about 175,000 tons of equipment and materials. The timeframe and specific delivery schedule is still under development. A more detailed traffic study will be completed in the AFC process.

5.13 Transmission Line safety

A detailed study will be performed to determine any increases in EMF levels or audible noise due to construction or operation.

5.14 Visual resources

Because the study area is not given a BLM-designated VRM classification, the BLM California Desert District Office requires the applicant to prepare a visual resource inventory (VRI) for the area, per *VRM Manual 8400*, in order to assign an interim VRM classification. A VRI can provide a better understanding of visual impacts arising from the proposed projects in order to determine visual impacts on viewers and the landscape by identifying several key observation points within view of the area in question; a contrast analysis is then performed that compares project features with features on the existing landscape to better analyze the potential impacts of the proposed projects.

Based on the findings of the VRI and subsequent interim VRM classification, a plan amendment for a proposed application would be required if the interim VRM class is determined to be incompatible with solar development (i.e., Class I or II). The *NECO Plan* did not assign VRM classes to the McCoy Soleil study area. Because of the distance of the BLM Wilderness Areas from the study area, visual impacts from a proposed solar development are not likely to be a significant constraint; however, a VRI is recommended to confirm this.

Once the land use designation is amended to Class III or IV, the area will accept major modifications of the landscape. The 600 foot tower will be the predominant change to the landscape. It is expected that the field of heliostats, though large, will ultimately have minimal impact to visual resources. At certain times of the day and from certain elevations, the mirror field will reflect the sky and resemble a large body of water. While the plant is operational, during peak sunny hours, the receiver tower at the top 60 feet of the central tower will glow brightly as sunlight is heating up the molten salt in the receiver tubes. This effect will create another bright light in the sky from certain vantage points, but as it only occurs when the sun is shining, this is projected to have less of an impact than a nighttime light would have. A more detailed analysis of visual impacts, including the views from different nearby locations, will be carried out for the AFC. It is expected that the project will be able to mitigate any visual impacts that are identified. For instance, targeted landscaping at nearby residences may be proposed to shield them from the view of the tower. Another possible mitigation that enXco proposes is to provide an appropriate viewing platform for the public to educate about the benefits of solar energy in providing electricity while decreasing dependence on fossil fuels and preventing the increase in emissions of greenhouse gases.

enXco

5.15 Waste Management

The McCoy Soleil will produce maintenance and plant wastes typical of power generation operations. Generation plant wastes include oily rags, broken and rusted metal and machine parts, defective or broken heliostats and electrical materials, empty containers, and other miscellaneous solid wastes including the typical refuse generated by workers. These materials will be collected by the local waste disposal.

There is no daily volume of waste generated by the cycle. There will be some removal of office waste and broken components from time to time, but these volumes will be small. Project wastes are not projected to significantly affect the capacity of local hazardous and non-hazardous waste facilities.

5.16 Water

Several ephemeral stream channels running southeast through this study area are visible on aerial photos. These stream channels appear to have connectivity to other streams and channels connecting to the Colorado River (a TNW). If the proposed project impacts the streams in the project area, an evaluation by the USACE must be performed to determine whether they are jurisdictional. Several large washes were viewed during a January 2009 visit to the study area although no water quality-limited segments (water bodies currently not meeting water quality standards) are listed as occurring near this study area (California State Water Resources Control Board 2008). The project area is potentially subject to Section 401 and 404 requirements.

5.16.1 Water Availability

Groundwater is available at the McCoy site, and enXco has requested the assistance of BLM in acquiring water rights to dig a field of wells.

enXco has undertaken a water study for the McCoy Soleil project site and determined that water will likely require a contract with the Bureau of Reclamation for groundwater extraction. The project area lies within a zone extending from the Colorado River to the west that has been designated by the USGS as the "accounting surface," which means that any person withdrawing water from under this surface must have an agreement with the Bureau of Reclamation.

enXco has determined that

- The project area is outside the boundaries of the Palo Verde Irrigation district, and therefore cannot contract water with this agency
- The BLM has an agreement with the Colorado River Board (CRB) for 1,150 acre-ft of water/year, some of which it does not use.
- The BLM is willing to work with enXco to determine how to make water available to solar projects in the Eagle Mountain to Blythe corridor
- The Lake Havasu, BLM office has determined that the Palm Springs Field office of the BLM will need to take the lead on this water issue.
- The Palm Springs office, though willing, has not yet chosen someone to lead the resolution of the water issue

In an effort to move this issue forward, enXco has informed Greg Miller, renewable energy manager for the California Desert District of the current status of water availability in the area. enXco is willing to take on a leadership role to help bring resolution to the challenge of finding water for the solar projects in the area.

Installing a well to obtain water for construction and operations would likely require a permit from the Riverside County Department of Environmental Health. Well yields in this groundwater basin average 1,650 gallons per minute. The McCoy Soleil study area is part of the Colorado River Hydrologic Region and the Palo Verde Mesa Groundwater Basin (California Department of Water Resources 2003).

5.16.2 Estimate of Daily and Annual Water Consumption Requirements

The proposed station is designed with a dry cooling tower for steam cycle cooling. This facility will require water for make-up of condensate due to normal relief valve losses and minor spills, general facilities and human consumption and water to wash the heliostats. Heliostat washing is a normal, continuous process that will occur regularly, with a wash water requirement of less than 100 acre-feet per year.

Water will be supplied from a well field developed at the project. A water tank will have a sufficient capacity for a one day operation at peak power generation. The water use can be divided into the following three categories based on the quality required:

(1) Service water which includes all other miscellaneous uses;
(2) Demineralized water for make-up to the steam Rankine cycle and mirror washing and
(3) Potable water.

The water will be treated using a conventional water treatment system to meet all plant needs. The plant will require a raw water storage tank, on the order of 2 million gallons, which will also contain a minimum of 300,000 gallons of water for fire protection capabilities. Steam cycle process water must meet stringent specifications for suspended and dissolved solids. This water will be processed by means of a demineralized water makeup system. enXco anticipates this will consist of multiple operations, concluding with mixed-bed demineralizers. The feedwater system will also include mechanisms to control dissolved oxygen, maintain a specific pH, and minimize scale formation. Demineralized water will also be used for the washing of heliostats. Potable water that meets regulatory standards for safe drinking water will be supplied from the local Water District or treated on-site. The potable system will supply water to sinks, toilets, showers, drinking fountains, and emergency eye wash safety showers.

Water Consumption Requirements	Approximate Consumption during Construction	Approximate Consumption during Operation
Steam Cycle makeup water (AF)	0	100
Mirror wash water (AF)	0	70
Air cooled condenser augmentation (AF)	0	430
Construction year 1 (AF)	1000	0
Construction subsequent years (AF)	150	0
Total annual (acre-feet/year)	575 (2 years)	600

5.16.3 Waste Water

Water wastes from miscellaneous plant equipment and water treatment system will be collected on-site and processed according to all required LORS. The sanitary wastewater from sinks, toilets, showers, other sanitary facilities will be discharged into an appropriate septic system and leach field that will be permitted under a WDR from the RWQCB. Water streams from plant drains and other miscellaneous equipment will be collected and recycled back into the plant where possible. No water quality impacts from the treatment and discharge of these streams is expected.

There will be minimal waste water during plant construction or operation. During construction, water will be used for dust mitigation, but not to the extent that runoff from the site is expected. Please see a discussion in the section on erosion control and stormwater drainage. Portable bathrooms will be provided during construction, as needed, and will be emptied offsite per regulations.

Water used to wash panels will be demineralized, and not contain any chemicals. The quantity will be carefully monitored to produce no appreciable runoff; that is, the water will soak directly into the ground below the panels, or evaporate, and not travel across the ground.

Sanitary wastewater from sinks, toilets, showers, and other sanitary facilities will be discharged into an appropriate septic system and leach field that will be permitted under a WDR from the RWQCB.

5.17 Mitigation Measures proposed by enXco

In seeking an appropriate site, and choosing the appropriate technology for McCoy Soleil, many factors were considered to minimize the impacts of the facilities. However, some impact will be unavoidable and will be required to be mitigated. Preliminary environmental studies have been completed for McCoy Soleil and the results of the studies are included in the sections above (Section 5). According to the preliminary environmental studies, possible mitigation may be required for air resources such as PM_{10}, biological resources including threatened and endangered species, cultural resources discovered on site, or other resources as determined in cooperation with agencies. Please see a discussion of possible mitigation in each section of Environmental Information, above.

Preliminary List of Required Permits and Permit Schedule

Required Permits and Permit Schedule		
Air Quality	DOC	An application will be submitted to the South Coast Air Quality Management District (SCAQMD) about the same time as the NEPA documents to obtain a determination of compliance (DOC).
	Federal Title V	May require Federal Operating Permit.
Biological	BLM Fieldwork Authorization	A Fieldwork Authorization will be required from BLM to complete the detailed biological studies for McCoy Soleil.
	Federal Endangered Species Act, HCP/Incidental Take Permit	Wildlife surveys will need to be completed and if endangered species are found, submitted to the U.S. Fish and Wildlife Service (USFWS) for agency approval under the ESA Section 7 Consultation. Depending on findings in the environmental surveys, enXco may require a Low Effect Habitat Conservation Plan for McCoy Soleil. An Incidental Take Permit (ITP) may be required under section 10 of the ESA. BLM will consult with the USFWS regarding the presence of desert tortoise.
	California Department of Fish and Game (CDFG) Incidental Take Permit (ITP)	Wildlife surveys will need to be completed and if endangered species are found, submitted to the CDFG for agency approval. Depending on findings in the environmental surveys, enXco may require an ITP under section 2081 (b) and (c) of the CA Endangered Species Act.
	USFWS and CDFG 2080.1 Consistency Determination	Submit the federal USFWS opinion incidental take permit to the CDFG to obtain concurrence of federal ITC

	RWQCB	It is anticipated that the RWQCB will take jurisdiction of the ephemeral drainages. Pre-notification will be required to obtain an individual permit.
Cultural	BLM Fieldwork Authorization and Cultural Resource Use permit	A Fieldwork Authorization will be required from BLM to complete the Class 3 cultural studies for McCoy Soleil. Any removal of archaeological resources will require a Cultural Resource Use permit from the BLM.
	Historic Preservation Act section 106 consultation	Consultation with the SHPO will be required if the project would affect any property listed in the NRHP; any new site would require NRHP eligibility evaluation
Geological and Soils	BLM Building permit	The BLM requirement will be specified in the Conditions of Approval pending approval of the ROW application
	BLM Grading permit	The BLM requirement will be specified in the Conditions of Approval pending approval of the ROW application
Hazardous Material	Unified Program Facility Permit	Riverside County Fire Department, Haz Mat division, requires a permit prior to storage of hazardous materials on site.
	Aboveground Storage Tank permit	Riverside County Fire Department, Haz Mat division, requires a permit prior to storage of hazardous materials in aboveground storage tanks on site.
Land Use	ROW for Solar Energy Development/NEPA Review	BLM for commercial solar facility, including transmission lines and access roads. BLM will publish an EIS for the project.
	ROW for Solar Energy Testing	BLM for solar testing equipment, prior to the ROW grant for Solar Energy Development
Paleo	BLM fieldwork authorization	No state or local permits will be required. A BLM Fieldwork Authorization will be required for paleo studies.
Transportation and Traffic	NDOT and Caltrans: Oversize load permit	California Department of Transportation requires permits for any oversized (gross weight or dimensions) vehicle deliveries. At least 10 days prior to oversize loads At least 7 days prior to oversize load on State Highways.
	Encroachment permit (for work in County ROW)	Submit plans showing work 30 days prior to construction work in public ROW
	Haz Mat Permit	Federal Motor Carrier Safety Administration; depends on nature of hazardous material transported

	FAA	FAA Form 7460-1; at least 30 days before the application for a construction permit is to be filed
Hazardous Waste	EPA ID No. and register as a Hazardous Waste Generator with Department of Toxic Substance Control	Takes 7-10 business days once the application form has been received
	Hazardous waste generator permit from Riverside Co EHS	Approximately 30 days prior to approval once Business Plan is complete
	Waste Discharge Requirements	Regional water quality control board may require permits
Water Resources	Section 404 Permit U.S. Army Corps of Engineers	If mapping of the washes on site determine that waters of the U.S. are present, a permit will be required from the U.S. Army Corps of Engineers
	NOI for construction phase storm water permit	Construction general permit required. A SWPPP that specifies BMPs for preventing construction pollutants from leaving the site. Approval will take about a month.
	California Regional Water Quality Control Board (CRWQCB) Section 401 Permit	Required if Section 404 permit (above) applies.
	CRWQCB NPDES and SWPPP	Industrial General permit required for operations phase. A separate SWPPP will be required that outlines the monitoring and reporting plan and BMPs for the solar plant.
	Well Drilling Permit	California Department of Water Resources, Southern District permit is required for drilling water wells
Health and Safety	Trenching and excavation permit	Submit completed permit application to any OSHA district of field office prior to commencing construction
	Permit to erect a fixed tower crane	Submit completed permit application to any Cal-OSHA district of field office 24 hours prior to commencing activity

Construction Process

Construction Phase	Description	Approximate Number and Type of Construction Equipment and Vehicles
Rough Grading	Grubbing, clearing and bulk grading,	Approximately 20 Scrapers, 5 Compactors, 4 Graders, 2 Loaders, 4 Dozers, 10 Water Trucks, 6 Water Pulls
Finish Grading	Final grading to finish grade	Approximately 4 Scrapers, 8 Graders, 1 Dozer, 4 Water Trucks
Roads, Foundations, Flatwork and Site Utilities	Construction of roads, excavation and construction of foundations for heliostats	Approximately 20 to 40 pieces of equipment will be present at any one time, including concrete trucks, concrete pumps, backhoes, excavators, loaders, graders, foundation drills, paving machines, drum rollers, fork lifts, tractors, dump trucks, small cranes and additional support vehicles.
Heliostat Assembly and Deployment	Field assembly of heliostats in temporary shop buildings constructed at the site. Installation of assemblies on cast-in-place piers, or other foundations.	Approximately 8 to 10 crews, each with one or two pieces of equipment including small cranes, forklifts, welding machines, trucks and tractors.
Power Block Construction	Construction of foundations, structural frames and buildings, installation of utilities and equipment, including the STG, condenser, pumps, buildings, ACC cooling structure, TES tanks, and central receiver tower.	An average of 12 to 18 pieces of equipment will be utilized for power block construction over the duration of the project, with more equipment being utilized during the early stages of foundation construction and frame erection. Equipment will include backhoes, excavators, foundation drills, concrete trucks, concrete pumps, forklifts, boom trucks, lifts, cranes, welders, trucks and other support vehicles.
Liquid Salt Preparation	Melting of the delivered dry salt product	Temporary propane fired auxiliary boiler, forklifts, loaders, and trucks.

Appendix C: Site Record Forms

3.0 PREHISTORIC OVERVIEW

The Precontact history of the region can be characterized by three general periods: the Paleoindian, the Archaic, and the Patayan. Summaries of these periods are presented below.

3.1 Paleoindian Period

The Paleoindian Period lasted from approximately 12,000 to 7,000 years before present (BP). This period is manifested in the Colorado Desert by the San Dieguito complex. Sites ascribed to this complex commonly contain assemblages of bifaces, choppers, scrapers, crescents, and other tools associated with a generalized hunting-gathering adaptation. Three separate phases have been suggested to represent a developmental sequence within the San Dieguito complex with each phase representing a step towards increasing technological complexity and diversity (Apple et al. 1997).

3.2 Archaic Period

The Archaic Period is characterized as a more diverse hunting-gathering tradition, which lasted from approximately 7,000 to 1,075 years BP. This period is poorly represented in the Colorado Desert region and it has been suggested that this area may have been largely abandoned during this period due to warm and dry conditions characterizing the Middle Holocene (Hayden 1976). An alternative hypothesis is that sites from this period may have been lost or eliminated by natural processes or obscured by later settlements (Weide 1976).

3.3 Patayan Period

The Patayan Period began after 1,075 years BP and lasted until the first Spanish explorers reached the area, around A.D. 1540. During this period, much of the region was populated by groups utilizing a distinctive ceramic technology that was characteristic of the Patayan cultural tradition. It is believed that these groups moved to the area at a time when Ancient Lake Cahuilla formed in the Salton Basin, southwest of the current project area. Lake Cahuilla became the westernmost extent of Patayan groups who populated a large area along the Colorado and Gila rivers and north to the present-day borders of Arizona, Utah, and Nevada. The Hohokam and Anasazi, two other Southwest cultural groups, bordered the Patayan to the southeast and northeast, respectively.

Although the origins of the Patayan are subject for debate, a transition from the Archaic Period to the Patayan Period is visible within the archaeological record. It appears that the adoption of Patayan ceramic technology coincides with a change in mortuary practices. A shift from burial to cremation practices indicates not only technological changes, but also fundamental shifts in cultural values. Although little is known about the organization of the Patayan, they were likely small, dispersed groups with exceptional mobility. Archaeological research has documented numerous trails and shrines that link resources separated by vast stretches of the Colorado Desert (e.g. Ezzo 1994). Most documented Patayan sites appear to consist of temporary camps with few architectural features other than small jacal structures (Cordell 1997). Archaeological sites in Arizona have produced marine shell, steatite, asphaltum, and turtle shells from California, further indicating that these early Patayan groups were extensive travelers and/or traders (Stone 1991). Patayan groups probably subsisted on a wide variety of hunted, gathered, and perhaps planted foods. At archaeological sites in the Salton Trough, numerous fish traps, fish bones, and shell middens indicate that some Patayan groups were highly dependent on exploitation of lacustrine resources.

The Patayan Period has been generally separated into three developmental phases that characterize cultural changes. The phases roughly coincide with the cyclic filling of Ancient Lake Cahuilla and correlate principally with changes in pottery types (Waters 1982). The Patayan I Phase (1,075 to 950 years BP) is characterized by a heavy influence of western Arizona Patayan on Colorado Desert populations (Waters 1982). The inception of this period has been dated by the association of intrusive Hohokam potsherds in two stratified Patayan sites in Arizona and five radiocarbon dates ranging from 1,125 (+/-80) years BP to

conditions of the region created competition for resources, theft of food, petty conflict, and frequently war (McCarthy 1986).

The inhabitants of the region near the Colorado River lived in flat-topped ramada-like dwellings. Ceramic vessels were made to store foodstuffs. The people hunted with the bow and arrow, and fished with nets and weirs. They built boats of balsa wood, and rafts were made of bundled bulrushes and reeds. In 1605, Don Juan de Oñate reported more than 16,000 Indians living in the lower river region between present-day Las Vegas and the tidewater (McCarthy 1986).

5.0 HISTORIC OVERVIEW

The first significant European settlement of California began during the Spanish Period (1769 to 1821) when 21 missions and 4 presidios were established between San Diego and Sonoma. Although located primarily along the coast, the missions dominated economic and political life over the majority of the California region during this period. The purpose of the missions was primarily Indian control, along with economic support to the presidios, forced assimilation of the Indians to Hispanic society, and conversion of the native population to Spanish Catholicism (Castillo 1978; Cleland 1941).

The Mexican Period (1821 to 1848) began with the success of the Mexican Revolution in 1821, but changes to the mission system were slow to follow. When secularization of the missions occurred in the 1830s, the vast land holdings of the missions in California were divided into large land grants called *ranchos*. The Mexican government granted ranchos throughout California to Spanish and Hispanic soldiers and settlers (Castillo 1978).

In 1848, the Treaty of Guadalupe Hidalgo ended the Mexican-American War and marked the beginning of the American Period (1848 to present). The discovery of gold the same year initiated the 1849 California Gold Rush, bringing thousands of miners and settlers to California, most of who settled in the north. For those settlers who chose to come to southern California, much of their economic prosperity was fueled by cattle ranching rather than by gold. California continued to grow, gaining the status of statehood in 1850. During the 1860s, severe floods and droughts slowed growth and bankrupted many ranchos and settlers (Castillo 1978; Cleland 1941).

Despite such setbacks, settlement in California continued throughout the remaining decades of the 19th century. Emigrants were lured to California though advertisements proclaiming mild weather, health benefits and opportunity. The first half of the 20th century saw steady increases in population, especially with the onset of the Great Depression as families sought work in various industries, especially that of agriculture throughout the central valley. One of the greatest booms to California population and economy came with America's entrance into World War II. The establishment of military bases and manufacturing plants associated with the war effort brought yet another wave of American emigrants westward where many settled permanently.

Desert cities developed more slowly than those in settlements closer to the coast or within fertile valley areas. The earliest European explorers to visit the Colorado River and the hostile desert area of Arizona were Francisco de Coronado and his company of men in 1540. The same year, the expedition of Hernando de Alarcón, sent by the Spanish government to find Coronado, towed boats up the Colorado River. While Alarcón was searching for the Coronado expedition, Coronado sent one of his officers, Melchior Díaz, on a supply-seeking foray with a small group of soldiers. Historians are not certain of the extent of the travels of either Alarcón or Díaz. Some, however, believe that Alarcón traveled up the Colorado River as far as present-day Blythe before turning back to Mexico, and that Díaz crossed the river in the Blythe area and explored the desert on the California side (Forbes 1965).

Little European activity took place in the harsh Colorado Desert over the next two centuries, except for occasional expeditions like that of Don Juan de Oñate, the Spanish colonizer of New Mexico. In 1605, Oñate and a company of men set out on a wealth-seeking expedition from the New Mexico colonies to

P2. **Location:** ▪ Not for Publication ☐ Unrestricted a. **County:** Riverside
Taken from 1976 site record:

b. **USGS 7.5' Quad:** Big Maria Mts. SW Date: 1975 T 4S ; R 23E; Unsectioned; SBM
c. Address: None
d. UTM: Zone 11 ; NAD 1927; 528560 mE/ 3743360 mN, 524300 mE/ 374360 mN (note missing # in second northing)
e. Other Locational Data (e.g., parcel #, directions to resource, elevation, etc., as appropriate): The site location was originally described as, "Trail runs parallel to jeep trail East Northeast for 4 miles (approx), then swings south-southeast for ⅛ mile and then due east for 2.5 miles to a junction with Hwy 95. Trail runs NW-SE along foot of Little Maria Mtns."

P3a. **Description** (Describe resource and its major elements. Include design, materials, condition, alterations, size, setting, and boundaries): This site was recorded in 1976 by Savio simply as a trail one meter wide and 9600 meters long. A portion of the recorded location was revisited in 1997 by Eighmey, O'Neill, and Giacomini, but the trail was not relocated. A separate portion was revisited during the current survey, but again, no trail was found. This portion may have been destroyed by the All American Pipeline or Midland Road.

P3b. **Resource Attributes** (List attributes and codes): AP13. Trail (Not Relocated)

P4. **Resources Present:** ☐Building ☐Structure ☐Object ☐Site ☐District ☐Element of District ☐Other (Isolates, etc.)

c. Address: City: Zip:
d. UTM: (Give more than one for large and/or linear resources) Zone 11 ; 528560,524300 ME/ 3743360 MN
e. Other Locational Data: (e.g., parcel #, directions to resource, elevation, etc., as appropriate) The trail was not relocated. The location information given above reflects the original site recording done by Savlo on June 29, 1976. A sketch map accompanying the initial recording indicates that a trail passing through section 36 was identified, extending east for about 10 miles, to Highway 95. (This is a portion of the "Halchidhomi" trail extending from the Blythe geoglyph to Redlands). It was recorded in the 1950's by Johnston and Johnston as RIV-53T. They only found segments preserved along the reconstructed route and in this area reported the trail but did not record it as preserved.

*P3a. Description: (Describe resource and its major elements. Include design, materials, condition, alterations, size, setting, and boundaries) The site is described as a trail running "NW-SE along foot of Little Maria Mtns". The area given is 1 meter by 9600 meters.

*e. Other Locational Data: (E.g., parcel #, directions to resource, elevation, etc., as appropriate)
There are two segments. The northernmost begins approximately 100 feet east of the intersection of Lovekin Boulevard and 18th Avenue, and heads southwest for 2,000 feet. The southernmost segment begins at the southwest corner of 24th Avenue and Neighbors Boulevard. This segment runs east-west and is the last 1,200 feet of the terminus at Ripley.

*P3a. Description: (Describe resource and its major elements. Include design, materials, condition, alterations, size, setting, and boundaries.)
The two segments are part of the Atchison, Topeka & Santa Fe Railroad (AT&SF) spur that stretches from Rice (Blythe Junction), California to its terminus in Ripley, California. The 49.4 mile AT&SF spur branches off of the Parker District branch line that runs between Cadiz, California and Parker, Arizona. Construction on this spur spanned from 1915-1920, with Ripley operations beginning October 1921. One of the rails is stamped "Colorado Sec 905 x 1912 OH" and a tie plate is marked "NES SEE-TP-3." The spur line is still in use, operated by the Arizona & California Railroad.

L8a. Photograph, Map or Drawing

L8b. Description of Photo, Map, or Drawing (View, scale, etc.)

Profile of railroad grade and tracks, McCoy Mountains in background, view towards southwest; taken 9/18/02; Photo #66.

L9. Remarks: The California Southern Railroad was organized in 1880, and construction of the tracks began in 1881. After 1884, the Atchison, Topeka, & Santa Fe Railway took over the California Southern Railroad as a subsidiary. The California Southern Railroad line from Cadiz, California to Matthie, Arizona was constructed in 1910. In 1915, due partially to the need for a rail line closer to mining operations north of Blythe, construction began on a branch extending south from Blythe Junction (now Rice) on the Cadiz-Matthie line to Blythe. This line was completed in 1916. The segment of railroad from Styx to Inca Siding was probably constructed in 1915 or 1916. The railroad line between Rice and Blythe was instrumental in the development of the Blythe-Midland region as a gypsum and manganese mining center in the early 20th century. On May 9, 1991, the Cadiz, California to Matthie, Arizona line, formerly of the California Southern Railroad, a subsidiary branch line of the Atchison, Topeka, & Santa Fe Railway, was purchased by the Arizona & California Railroad (Blaszak 2002; Gunther 1984; van Till Warren et al. 1981).

This branch of the railroad has not been formally evaluated for NRHP eligibility. However, given the high level of integrity of this segment and the branch's association with the California Southern and Atchison, Topeka, & Santa Fe Railroads, which played prominent roles in the historical development of transportation and mining in the Blythe-Midland region, the railroad is likely to be eligible for inclusion in the NRHP under Criteria A and C.

Subject RE: EnXco meeting

Hi Ian, I forgot to attach our Golden Eagle (GE) inventory and monitoring protocol. The FWS is also currently developing a protocol to conduct non-breeding season surveys which will send to you when it's available.

During our recent meeting, I think I mentioned that GE surveys had been conducted in Spring 2010 for several projects along the I-10 corridor, including the Blythe project, and that the results of these 2010 surveys may be applicable for EnXco's McCoy project. However, while the 2010 surveys provide valuable information about GE in the vicinity, I believe EnXco's McCoy project is outside of the area surveyed for the Blythe project. Also, per the protocol, survey results are only valid for one year since GE nesting patterns can change annually. Therefore, GE surveys should be conducted for EnXco's McCoy project following the FWS protocol. This survey effort should be coordinated through the BLM prior to initiation to maximize the effort and minimize impacts to bighorn sheep.

USFWS Interim GE Inventory and Monitoring Protocols_Feb 2010.pdf

Thanks, Tannika

Save paper - think before you print.

Hi Ian, we appreciate EnXco meeting with us as well. I recommend reviewing that CEC's revised staff assessments for the Blythe and Genesis projects to get an idea of the type of general and species-specific avoidance, minimization, and mitigation measures required by the CEC, BLM, CDFG and/or FWS for other large-scale solar projects along the I-10 corridor. Most, if not all, of these measures would likely be applicable for EnXco's proposed Eagle Mountain, McCoy, and Mule Mountain projects.

http://www.energy.ca.gov/2010publications/CEC-700-2010-004/CEC-700-2010-004-REV1.PDF

http://www.energy.ca.gov/2010publications/CEC-700-2010-004/CEC-700-2010-004-REV1.PDF

I also suggest reviewing the FWS' Raven Mitigation summary document available on the CEC's website.

http://www.energy.ca.gov/sitingcases/solar_millennium_blythe/documents/others/2010-06-01_USFWS_Summary_Raven_Mgmt_Plan_TN-56936.pdf

Tannika Engelhard's email

The FWS is currently finalizing guidance on desert tortoise translocation which I'll send you as soon as it's publically available. In the meantime, you can review our comments on the desert tortoise translocation plans for the Blythe and Palen projects available on the CEC's website.

http://www.energy.ca.gov/sitingcases/solar_millennium_blythe/documents/others/2010-04-29_Carlsbad_Fish_and_Wildlife_Office_Comments_on_Draft_Desert_Tortoise_Translocation_Plans_TN-56469.pdf

Also, as stated during our recently meeting, the agencies would be happy to review and discuss any proposed species survey protocols prior to their initiation.

Let me know if you need any other information regarding desert tortoise or golden eagles. Thanks, Tannika

Subject RE: EnXco meeting

Allison, et al.,

Thank you for the invitation and the opportunity to discuss our proposed BLM solar projects. We are encouraged by our biological resource team's findings on our McCoy and Eagle Mountain and appreciate the early, inclusive dialogue hosted by the BLM. We look forward to keeping that dialogue going throughout the design and permitting process. To that end, enXco would like to reiterate that we are open to thoughts from the agencies on which critical biological studies to prioritize this summer and fall, as we work through our project analysis.

Feel free to email, or call me at your convenience. Additionally, I will follow up by email individually. Thanks again Allison and Mark, for hosting us on Wednesday.

Kind Regards,

Tannika Engelhard's email

Pagel, J.E., D.M. Whittington and G.T. Allen. 2010. Interim Golden Eagle inventory and monitoring protocols; and other recommendations. Division of Migratory Birds, U.S. Fish and Wildlife Service.

I. Purpose

This document identifies the minimum inventory and monitoring effort recommended for determining and evaluating potential Golden Eagle (*Aquila chrysaetos canadensis*) use of habitat including nest sites, roosts, and territories, as well as the rationale for identifying and evaluating foraging locations during breeding and non-breeding periods. It also outlines the minimum monitoring techniques to ascertain occupancy and reproductive success at territories. These field efforts are the mutual responsibility of agencies authorizing activities and their permittees (i.e. action agency; see Glossary). They are essential components for avoiding and minimizing disturbance and other kinds of take, including lethal take, and are a necessary component of short and long-term site specific monitoring and management of local Golden Eagles and regional Golden Eagle populations. The data gathered will provide information on the baseline circumstances for evaluation of permit applications and foundation for permit conditions, as well as assist planners so they may conduct informed impact analyses and mitigation during the National Environmental Policy Act (NEPA) process. Data collected via this effort will also help:

1. Determine the fate and reproductive trends of regional nesting populations via collating information from observed territories.
2. Document and list historical and unsurveyed habitat for future analysis to assist in determining local and regional population trajectories.
3. Provide information to document whether local Golden Eagle conservation efforts are meeting goals for improvements in the status of Golden Eagle.
4. Provide a foundation for evaluation of whether and which activities or conditions may be affecting Golden Eagle.

II. Background

Golden Eagles are protected by the Migratory Bird Treaty Act, and the Bald and Golden Eagle Protection Act (Eagle Act), which both Acts prohibit take. Take means *pursue, shoot, shoot at, poison, wound, kill, capture, trap, collect, destroy, molest,* or *disturb*. When the Bald Eagle was delisted under the Endangered Species Act (ESA), and in order to improve management of both species of eagles under the Eagle Act, the U.S. Fish and Wildlife Service (Service) undertook a series of management actions, including:

- **Codifying a regulatory definition of "disturb"** under the Eagle Act (see 72 FR 31132, June 5, 2007). *Disturb* means to agitate or bother a Bald or Golden Eagle to a degree that causes, or is likely to cause, based on the best scientific information available, 1)

injury to an eagle, 2) a decrease in its productivity, by substantially interfering with normal breeding, feeding, or sheltering behavior, or 3) nest abandonment, by substantially interfering with normal breeding, feeding, or sheltering behavior.

- **Proposing permit regulations** to (1) Create a new permit type to authorize take of Bald Eagles and Golden Eagles that is associated with, but not the purpose of, the activity; and (2) Create a second new permit type to authorize purposeful take of eagle nests that pose a threat to human or eagle safety (subsequently broadened to accommodate additional circumstances). The regulations were finalized on September 11, 2009 (74 FR 43686).

Summary of the new regulations.

Permits issued under 50 CFR § 22.26 authorize take of Bald Eagles and Golden Eagles, where the take is associated with, but not the purpose of the activity, and cannot practicably be avoided. Most take authorized under this section will be in the form of disturbance; however, permits may authorize lethal take that results from, but is not the purpose of, an otherwise lawful activity. Purposeful take will not be authorized under § 22.26.

The second new permit regulation, at 50 CFR 22.27, establishes permits for removing eagle nests where (1) necessary to alleviate a safety hazard to people or eagles, (2) necessary to ensure public health and safety, (3) the nest prevents the use of a pre-existing human-engineered structure, or (4) the activity, or mitigation for the activity, will provide a net benefit to eagles. Only inactive nests during the non-breeding season may be taken, except in the case of safety emergencies.

Regulations under § 22.27 authorize removal and/or relocation of active and inactive eagle nests in cases where genuine safety concerns for people, eagles, or both, necessitate the take. Examples include: (1) a nest tree that appears likely to topple onto a residence; (2) at airports to avoid collisions between eagles and aircraft; and (3) to relocate a nest built within a reservoir that will be flooded.

Both regulations are provided for by the Eagle Act which gives the Secretary of the Interior the authority to permit the limited take of Bald Eagles and Golden Eagles "for the protection of . . . other interests in any particular locality." Additionally, both new regulations:

- Are applicable to Golden Eagles as well as Bald Eagles.
- Authorize take only where it is compatible with the preservation of the eagle. For purposes of these regulations, "compatible with the preservation of the Bald Eagle

and the Golden Eagle" means consistent with the goal of stable or increase of breeding populations.

- Authorize take only where it cannot practicably be avoided.
- Include provisions for programmatic take. Programmatic take (take that is recurring and not in a specific, identifiable timeframe and/or location) will be authorized only where it is unavoidable despite implementation of comprehensive measures developed in cooperation with the Service to reduce the take below current levels.

Additional needs for Golden Eagle information and evaluation.

As part of an adaptive management approach to the permits and eagle management, the Service will assess, at least every five years, overall population trends along with annual report data from permittees and other information to assess how likely future activities are to result in the loss of one or more eagles, a decrease in productivity of Golden Eagles, and/or the permanent loss of a nest site, territory, or important foraging area. Therefore, implementation of the new permit regulations will entail requirements for cumulative effects analyses and identifying the impacts of an activity. We include them here to provide the context and framework for the protocols and recommendations in this document.

Cumulative effect considerations.

Whether the take is compatible with eagle preservation includes consideration of the cumulative effects of other permitted take and additional factors affecting eagle populations. Cumulative effects are defined as: *"the incremental environmental impact or effect of the proposed action, together with impacts of past, present, and reasonably foreseeable future actions"* (50 CFR 22.3). Numerous relatively minor disruptions to eagle behaviors from multiple activities, even if spatially or temporally distributed, may lead to disturbance that would not have resulted from fewer or more carefully sited activities. The accumulation of multiple land development projects or siting of multiple infrastructures that are hazardous to eagles can cumulatively reduce the availability of alternative sites suitable for breeding, feeding, or sheltering, resulting in a greater than additive risk of take to eagles.

To ensure that impacts are not concentrated in particular localities to the detriment of locally-important eagle populations, cumulative effects need to be considered at the population management level—*Service Regions* for Bald Eagles and *Bird Conservation Regions* for Golden Eagles—and, especially for project-specific analyses, at local area population levels (the population within the average natal dispersal distance of the nest or nests under consideration). Eagle take that is concentrated in particular areas can lead to effects on the larger management population because 1) disproportionate take in local populations where

breeding pairs are 'high' producers may reduce the overall productivity of the larger population; and 2) when portions of the management population become isolated from each other the productivity of the overall management population may decrease.

~~Identifying the Impacts of the Activity~~

The applicant for an Eagle Act permit (who can be a project proponent or the agency preparing the NEPA), has four subtasks to determine the likely effects of a project or activity on eagles:

a. Collection and synthesis of biological data. The applicant is responsible for providing up-to-date biological information about eagles that breed, feed, shelter, and/or migrate in the vicinity of the activity that may potentially be affected by the proposed activity. Biological information can include locations and distribution of nests, delineation of territories, prey base, general composition and relative abundance, and productivity data.

b. Identifying activities that are likely to result in take. As part of the permit application, the applicant must include a complete description of the actions that: (1) are likely to result in eagle take, and (2) for which the applicant or landowner has some form of control. For most applications, the activity will be specific and well-defined (e.g., home construction; water use development) or land use activity (e.g., forestry). For larger-scale permits, applicants will need to determine the extent of impacts they want to include in the permit authorization and, if necessary, which ones they wish to exclude.

c. Avoidance and minimization measures. Applications for a § 22.26 permit must document the measures to which the applicant will commit to avoid and minimize the impacts to eagles to the maximum degree practicable.

d. Quantifying the anticipated take. The amount of take to be authorized under a permit depends on a variety of factors, including: (1) the number of eagles that breed, feed, shelter, and or migrate within the activity area, (2) the degree to which the eagles depend on that area for breeding, feeding, or sheltering, or migration, and thus are more likely to be present and affected, (3) the potential of that type of activity in general to take eagles, (4) the scale of the activity, and (5) the measures the applicant will undertake to avoid and minimize the take.

Federal agencies have additional responsibilities to Golden Eagles under Executive Order 13186 (66 FR 3853, January 17, 2001), which reinstated the responsibilities of Federal Agencies to comply with the Migratory Bird Treaty Act of 1918. The Executive Order establishes a process for Federal Agencies to conserve migratory birds by avoiding or minimizing unintentional take and taking actions that benefit species to the extent practicable. Agencies are expected to take

reasonable steps that include restoring and enhancing habitat. Environmental analyses of Federal actions required by NEPA or other environmental review processes must evaluate the effects of actions and Federal agency plans on migratory birds, including Golden Eagles.

Golden Eagle populations are believed to be declining throughout their range in the contiguous United States (Harlow and Bloom 1989, Kochert and Steenhof 2002, Kochert et al. 2002, Good et al. 2007, Farmer et al. 2008, Smith et al. 2008, 74 FR 46836-46879). The Service has modeled current data (USFWS 2009, Appendix C), employing Moffat's equilibrium (Hunt 1998) and Millsap and Allen's (2006) analysis of anthropogenic demographic removal, and estimated that the floating (non-breeding and surplus) component of the Golden Eagle population in some areas may be limited at this time. Data from the Western EcoSystems Technology Inc. surveys from 2006 – 2009 may suggest a decline since 2006 in the total Golden Eagle population within the area covered by the surveys (Neilson et al. 2010, USFWS 2009, Appendix C). Significant Golden Eagle breeding failures have been reported in some areas of the southwestern United States (WRI 2009), and declines in counts of migratory Golden Eagles have been reported in most areas in the western United States (Farmer et al. 2008, Smith et al. 2008), although it is unclear if the latter is linked to a decrease in the number of eagles.

III. Management Need

Prior to initiating inventory and monitoring efforts, land management agencies and/or proponents of land use activities should first assess all existing recent and historical data available on eagles, including their nests, reproductive activity and chronologies, natal dispersal, pertinent data from VHF and satellite telemetry, winter roosts, migration corridors, and foraging habitats contained by and within 4 - 10 + miles of areas slated for development or authorizations for increased human activity. This background search of available information may yield few data, but is necessary to alert project proponents and regulatory staff about data gaps, and existing knowledge of Golden Eagle for that area. Inventory, monitoring, and research activities may then be identified and funded to fill in site specific information gaps to avoid take of Golden Eagle. Specific recommendations for the number of years needed for baseline data and measures to avoid take should be developed in coordination with the Service, and, to reduce redundancy between management and permitting requirements, consistent with permit requirements outlined in the Draft Implementation Guidelines for the new rules (available fall 2010).

Projects in Golden Eagle breeding home ranges on federal, state, and private land possibly will have direct, indirect, and cumulative effects associated with or exacerbated by, factors such as: recreation disturbance, electrocution, urbanization, illegal shooting, invasive species altering prey densities, lead poisoning, other contaminants, climate change, and prolonged drought

which affects predator and prey abundance and distribution. In many cases, existing data may not be adequate for NEPA, planning, or permitting purposes. Therefore, inventory and subsequent monitoring of Golden Eagles and components of their habitats are important to 1) develop a baseline prior to project planning and prior to project development in Golden Eagle habitat, 2) analyze impacts to the species, 3) continue to evaluate and report on the effects of the action and mitigation on Golden Eagles, 4) essential to adaptive management approaches, and 5) provide information that may be required for permits.

Project design, type, and siting of project footprint and infrastructure are critical to avoid disturbance and take of Golden Eagle. In the Final Environmental Assessment on the rule and in the draft Implementation Guidance, the Service recommends that when planning locations of infrastructure and project boundaries, action agencies and project proponents consider life-history components such as productivity, age-class survival, dispersal, migration, winter-concentration behavior, and foraging behavior during breeding and non-breeding seasons in a concerted effort to avoid lethal take. The Service recommends use of the best available or gathered information applicable to the location of the project or plan, but also encourages efforts to conduct further research. For permitting purposes however, and to determine the likelihood and magnitude of take, as well as effectiveness of mitigation, monitoring will need to yield productivity information.

Note: This document does not address site specific observations for transitory and wintering eagles; these protocols will be forthcoming. Although the life history for transitory and wintering eagles is not discussed at length here, that does not imply a lack importance for site-specific observations from the Service's perspective. The document provides general recommendations for factors to consider outside nesting, until more specific protocols are developed.

IV. Basic Golden Eagle Ecology

This account is not intended as a compendium of Golden Eagle natural history, biology, ethology, or ecology; please refer to Watson (1997), Palmer (1988) and Kochert et al. (2002) for more detailed information.

Where they exist, Golden Eagles are an upper-trophic aerial predator, and eat small to mid-sized reptiles, birds, and mammals up to the size of mule deer fawns and coyote pups (Bloom and Hawks 1982). They also are known to scavenge and utilize carrion (Kochert et al. 2002)

Golden Eagles nest in high densities in open and semi-open habitat, but also may nest at lower densities in coniferous habitat when open space is available, (e. g. fire breaks, clear-cuts, burned areas, pasture-land, etc.). They can be found from the tundra, through grasslands,

woodland-brushlands, and forested habitat, south to arid deserts, including Death Valley, California (Kochert et al. 2002). Historically, Golden Eagles bred in the Plains and Great Lake states. Golden Eagles currently breed in and near much of the available open habitat in North America west of the 100th Meridian, as well as in eastern United States in the northern Appalachian Mountains (Palmer 1988, Kochert et al. 2002). Lee and Spofford's (1990) review of the literature for the eastern portion of the United States suggests historical nesting Golden Eagles south of New York in the Appalachians was unlikely. Nesting of introduced Golden Eagles have been reported in Tennessee and northwestern Georgia (Kochert et al. 2002), however it is currently unknown if these territories are still extant.

A nesting territory for the purpose of this monitoring protocol has been previously defined by Steenhof and Newton (2007), i.e. an area that contains, or historically contained, one or more nests within the home range of a mated pair: a confined locality where nests are found, usually in successive years, and where no more than one pair is known to have bred at one time.

Golden Eagles avoid nesting near urban habitat and do not generally nest in densely forested habitat. Individuals will occasionally nest near semi-urban areas where housing density is low and in farmland habitat; however Golden Eagles have been noted to be sensitive to some forms of anthropogenic presence (Palmer 1988). Steidl et al. (1993) found when observers were camped 400 meters from nests of Golden Eagles, adults spent less time near their nests, fed their juveniles less frequently, and fed themselves and their juveniles up to 67% less food than when observers were camped 800 meters from nests. In studies of Golden Eagle populations in the southwest (New Mexico and Texas) and the Front Range of the Rocky Mountains (New Mexico, Colorado and Wyoming), Boeker and Ray (1971) reported that human disturbance accounted for at least 85% of all known nest losses. Breeding adults are sometimes flushed from the nest by recreational climbers and researchers, sometimes resulting in the loss of the eggs or juveniles due to nest abandonment, exposure of juveniles or eggs to the elements, collapse of the nest, eggs being knocked from the nest by startled adults, or juveniles fledging prematurely. However, Golden Eagles rarely flushed from the nest during close approaches by fixed-wing aircraft and helicopters during various surveys in Montana, Idaho, and Alaska (Kochert et al. 2002).

Golden Eagles nest on cliffs, in the upper one third of deciduous and coniferous trees, or on artificial structures (windmills, electricity transmission towers, artificial nesting platforms, etc.; Phillips and Beske 1990, Kochert et al. 2002). Golden Eagles build nests on cliffs or in the largest trees of forested stands that often afford an unobstructed view of the surrounding habitat (Beecham 1970, Menkens and Anderson 1987). Usually, sticks and soft material are

added to existing nests, or new nests are constructed to create a strong, flat or bowl shaped platform for nesting (Palmer 1988, Watson 1997, Kochert et al. 2002). Sometimes Golden Eagle will decorate multiple nests in a single year; continuing to do so until they lay eggs in the selected nest. The completed nest structure(s) can vary from large and multi-layered; or a small augmentation of sticks in caves with little material other than extant detritus (Ellis et al. 2009). Each Golden Eagle territory may have anywhere from 1 to 14 alternative nests, with 1 to 6 nests per territory being the norm (Palmer 1988, Watson 1997, Kochert et al. 2002).

Onset of courtship and nesting chronology

Courtship for Golden Eagles involves stick-carrying, display flights, and vocalization (Ellis 1979, Kochert et al. 2002). Golden Eagles partake in undulating flight, however undulating flight has been observed year- round and is thought to be associated more with aggression and territory defense than with courtship (Newton 1979, Harmata 1982, Collopy and Edwards 1989, Watson 1997).

Nesting chronologies vary however there are some generalities. In California and in Texas, courtship at territories start in mid to late December (Palmer 1988, Hunt et al. 1997, D. Bittner pers. com); in Texas eggs have been detected as early as November (Olberholser and Kincaid 1974, *in lit.*). In Utah, courtship can commence in January. In northern tier states at upper latitudes and higher elevation sites, egg laying can occur as early as February and March, before late winter snows and storms have abated (Palmer 1988).

Golden Eagles lay 1 to 4 eggs, with 4 egg clutches rare. Most nests have 2 eggs. The laying interval between eggs ranges between 3 to 5 days. Incubation commences as soon as the first egg is laid, and hatching is asynchronous and can begin as early as late January in southern California (Dixon 1937, Hickman 1968), mid April to late May in southwest Idaho (Kochert et al. 2002) and late March–early May in central and northern Alaska (McIntyre 1995, Young et al. 1995; Fig. 3). In Texas, eggs have been noted from November to June (Oberholser and Kincaid 1974, in lit.). In the northeast United States, eggs have been laid in March/April (Palmer 1988). For more detail, please refer to Kochert et al. 2002 (Appendix 2).

Migration and Wintering

Golden Eagles will migrate from the Canadian provinces and northern tier and northeastern states to areas that are milder in the winter and/or may have less snow cover. Wintering Golden Eagles have been noted in all states in the continental U.S. (Wheeler 2003, 2007). Some segments of the population are non-migratory, and can be found near their nest sites throughout the year. See Kochert et al. 2002 for detailed listing of winter range.

Roosts or gathering behavior

Golden Eagles are not known to roost communally as is common with wintering Bald Eagles in some areas of the United States, but will gather together if local food sources are abundant. A caveat to this is that Golden Eagles have perched with bald eagles where there have been large concentrations of waterfowl or carrion (Palmer 1988).

V. Golden Eagle Responses to Disturbance

Golden Eagles, as with other raptors, visibly display behavior that signifies disturbance when they are stressed by anthropogenic activities; whether it is a lone hiker walking 1000 meters or more from a nest, or extended construction or recreation activities 2000 – 5000 meters from a territory. These postures, movements and behaviors can be overt. However with Golden Eagles, disturbance behaviors are often subtle and require an experienced observer. Olendorff (1971), Fyfe and Olendorff (1976), and Olsen and Olsen (1978) identified considerations when human interactions may disturb nesting activities, and how to ascertain critical distances to avoid agitating nesting, roosting, and foraging raptors. Factors affecting critical distances included:

a. Mannerisms of intruder.

b. Size of intruder.

c. Stage of breeding cycle.

d. Topography and exposure of intruder in relation to bird.

Golden eagle behavior varies among individuals and can be affected by previous experiences. However, some behavioral generalities relative to direct and indirect disturbance include the following:

- Agitation behavior (displacement, avoidance, and defense)
- Increased vigilance at nest sites
- Change in forage and feeding behavior
- Nest site abandonment

Of the preceding behaviors, nest-site abandonment can be readily identified as constituting take under the Eagle Act, as it is specifically cited in the definition of 'disturb'. The other behaviors, when considered cumulatively, may be evidence that activities are interfering with normal breeding behavior and are likely to lead to take. Human intrusions near Golden Eagle

nest sites have resulted in the abandonment of the nest; high nestling mortality due to overheating, chilling or desiccation when young are left unattended; premature fledging; and ejection of eggs or young from the nest (Boeker and Ray 1971, Suter and Joness 1981).

VI. Overall Objectives of the Golden Eagle Survey Protocol

This survey protocol is intended to standardize procedures to inventory and monitor Golden Eagles within the direct and indirect impact area of planned or ongoing projects where disturbance or lethal take from otherwise permitted human activities is possible. This protocol will; 1) identify eagle use areas, 2) identify and minimize potential observer-related disturbance to Golden Eagles by surveys when conducted by qualified and experienced raptor biologists.

Additionally, data collected using this protocol may be used for, at a minimum, 1), sampling other geographic areas where suitable habitat may be present; 2) short and long-term analysis of Golden Eagle occupancy and productivity at known nest sites, and historical locations where observation to determine occupancy maybe necessary; 3) identification and evaluation of potential disturbance factors. If followed, this protocol will standardize data collection for potential local and regional analysis of long-term occupancy, productivity and eagle use trends. This protocol was developed as minimum standards, and as such may require additional area-specific detail if used for research purposes.

Objectives of inventory and monitoring

The first objective of these surveys is to provide methods to identify areas occupied by Golden Eagles and select factors their behavior ecology. Additional objectives of these surveys include:

1. Record and report occupancy and productivity of local Golden Eagle territories.
2. Document and list historical and unsurveyed habitat for future analysis to assist in determining local and regional population trajectories.
3. Determine nesting chronologies.
4. Provide information to document whether local Golden Eagle conservation efforts are meeting goals for improvements in the status of Golden Eagles or meeting permit conditions.
5. Provide a foundation to evaluate whether and which activities or conditions may be affecting Golden Eagles.

6. Document foraging behavior, diet and habitat use within breeding and non-breeding home ranges.

VII. Inventory Techniques

CAUTION

Golden Eagles are one of several cliff and tree dwelling species sensitive to human disturbance. Monitoring eagles in a manner that 'disturbs' them, and causes them to be 'agitated or bothered' can cause nesting failure, and permanent site abandonment, constituting take under the Eagle Act.

These monitoring protocols should facilitate observer caution and identify techniques that will minimize potential for take of Golden Eagles. For additional information regarding preventing observer disturbance while surveying raptors, please refer to Fyfe and Olendorff (1976).

Inventory

Inventories for Golden Eagles should occur if nesting, roosting, and foraging habitat are contained within the project boundary and exist within 4 – 10 air miles from the project boundary. Local and regional Golden Eagle habitat variability will dictate the distance from the project boundary where surveys will occur; distances will be greater in xeric (arid) habitat, or where local prey may not be abundant. The Service will be basing its site-specific evaluations and final determinations on local conditions, not national averages.

Nesting habitat

This account is not intended as a compendium of Golden Eagle habitat available and used in North America; please refer to Palmer (1988) and Kochert et al. (2002) for more detailed information.

Golden Eagles use a wide variety of habitat throughout North America. Small xeric mountain ranges in the Mohave and Great Basin deserts, forested habitat in the Pacific coastal, southern desert, Great Basin, Rocky, Sierra, and Cascade Mountain ranges are also key nesting areas. Local and regional variation of nesting habitat should be considered prior to surveys; however should include cliff, desert scrub, juniper woodland, and forested habitat. For example, in the northern Great Basin, Golden Eagles nest on cliff and in scrub-forest habitat; surveys of both types of substrates are urged prior to projects that have a potential to affect eagles. Identification criteria for nesting habitat at the local scale should take place in coordination with the Service, State, or Tribal wildlife agencies, and raptor experts.

VII.a. Procedures for aerial and ground inventory and monitoring surveys

Golden Eagles generally show strong fidelity to the nesting area annually. Occupancy determination is the most important goal of nest searches. Considerable suitable habitat exists in western North America which has never been adequately surveyed. Inventory surveys should examine habitat where Golden Eagles are not currently known to exist but habitat may be present, as well as previously inventoried areas to detect new activity. Monitoring surveys examine all historical and extant territories where Golden Eagles have been detected either previously or in the current survey.

A nesting territory or inventoried habitat should be designated as unoccupied by Golden Eagles ONLY after at least 2 complete aerial surveys in a single breeding season. In circumstances where ground observation occurs, at least 2 ground observation periods lasting at least 4 hours or more are necessary to designate an inventoried habitat or territory is unoccupied as long as all potential nest sites and alternate nests are visible and monitored. These observation periods should be at least 30 days apart for inventory, and at least 30 days apart for monitoring of known territories. Intervals between observations at occupied nesting territories may need to be flexible and should be based on the behavior of the adults observed, the age of any young observed, and the data to be collected (see below, Section IX). Dates of starting and continuing inventory and monitoring surveys should be sensitive to local nesting (i.e. laying, incubating, and brooding) chronologies, and would be conducted during weather conditions favorable for aerial survey and/or monitoring from medium to long range distances (+ 300 – 700 meters).

The first inventory and monitoring surveys should be conducted during courtship when the adults are mobile and conspicuous. When survey of historical territories is conducted, observers should focus their search on known alternative nests, and also carefully examine the habitat for additional nests which may have been overlooked or recently constructed. A 'decorated' nest will be sufficient evidence to indicate the probable location of a nesting attempt. If a decorated nest or pair of birds is located, the search can then be expanded to inventory likely habitat adjacent to the discovered territory to see if additional golden eagle territories can be observed.

Note: Identification of alternate nests will be required by the Service for determination of relative value of individual nests to a territory in cases of applications for permits to take 'inactive' nests, and when determining whether abandonment of a particular nest is likely to result in abandonment of a territory. The Service has determined that territory loss or permanent abandonment of a territory is a greater impact to populations than temporary abandonment of a nest.

Weather: Avoid searching potential and known nesting locations during periods of heavy rain, snow, high winds, or severe cold weather. Golden Eagles should not be induced to flush at any time during the survey period. Flushing when the adults are incubating or have small young can be particularly hazardous for successful nesting, and could constitute lethal disturbance take. High temperatures also may cause problems for successful viewing over long distances due to heat waves. Further, observer related incidences of causing flight of adults that are shading young to prevent overheating during high temperatures may cause mortality of the young. Observation for Golden Eagles during inclement weather is impractical, uncomfortable, and unsafe for Golden Eagles and observers. Weather will be recorded by the observer.

Time of day: Aerial surveys should be conducted, at the beginning of the day if winds permit. Likewise, ground surveys should be initiated, where possible, in morning hours when the air is still to avoid heat waves. Prime observation periods are around dawn, or shortly thereafter. In some cases the angle of the sun in relation to the cliff can be a more important issue, and some cliffs are better observed in afternoon light, however observations of adult behavior that are used to determine nesting chronologies may be conducted during most of the day. Observers should be aware of the angle of the sun in relation to the observation post and the nest. Some sites are plagued by afternoon winds, heat waves, or dust storms; local observation conditions should be taken into account prior to establishing viewing periods. Time of day will be recorded by the observer.

Time of year: Breeding surveys for Golden Eagles are latitude and elevation dependent; however, their nesting season ranges in the contiguous United States from 01 January to 31 August (Kochert et al. 2002). Nesting failures and seasonal variations should be considered as potential anomalies to 'normal' behavior and nesting chronologies. Dates to be used as a cut-off period for observation and reporting of nesting failures or non-nesting status will vary per region. The dates listed below are to be used as general guides, and should not be used as final nest site failure survey determination dates. Location-specific determination dates should be developed in coordination with the Service, State, or Tribal wildlife agencies, and raptor experts.

Duration of stay at observation points: Ground observers will survey from observation points for a minimum of 4 hours, unless observations yield Golden Eagle presence, or Golden Eagle behavior indicate eggs or young, or observation suggests the observer is disturbing the birds. Slowly walking and observing all potential nesting substrate can be used to completely inventory potential habitat. Observation periods may last longer as longer observation periods may be necessary to accurately determine nesting chronologies. Duration of stay at known or suspected territories during helicopter reconnaissance, or during ground observation periods will be recorded by the observer.

VII.b Aerial surveys

Helicopters are an accepted and efficient means to monitor large areas of habitat to inventory potential habitat and monitor known territories only if accomplished by competent and experienced observers. They can be the primary survey method, or can be combined with follow-up ground monitoring. Disturbance to eagles is minimal only WHEN accepted aerial practices and techniques are followed. NOTE: Ground surveys can be used when their use is more efficient, or when other circumstances (i.e. bighorn sheep lambing areas) require this method.

Coordination between state and federal agencies is an important aspect of aerial surveys to develop acceptable search criteria to be used for identifying likely suitable nesting habitat and locating nests, as well as to be become acquainted with potential hazards and air space restrictions. Survey pilots should be aware of potential ground hazards within the habitat to be examined, including marked and unmarked transmission and wires. Other hazards to surveyors include rock-fall or tree fall from above the helicopter, raptors or other birds colliding with the helicopter, and collision with other aircraft. Although pilots are often the first to note a flying raptor during surveys, some accidents involving wildlife researchers have been attributed to the pilots focusing on the survey, rather than giving their complete attention to flying the helicopter.

Helicopters used for surveying Golden Eagle habitat should be light utility, i.e. small to medium sized (e.g. MD-500/520, Eurocopter 145, Bell Jet-Ranger 206, UH-72,) capable of vertical mobility in warm temperatures and higher elevations. Inventories for raptors can be conducted with the main observer door(s) removed (which may provide more lateral and horizontal

visibility), or with the doors closed. The decision regarding observer doors should remain a personal choice, with the safety of pilots and observers as the primary determinant.

Cliffs should be approached from the front, rather than flying over from behind, or suddenly appearing quickly around corners or buttresses. Inventories should be flown at slow speeds, ca. 30 – 40 knots. However, detection of nests may require slower speeds, e.g. 20 knots, while between nest speeds can be higher (+ 60 knots). All potentially suitable nesting habitats (as identified in coordination with the Service) should be surveyed; multiple passes at several elevation bands may be necessary to provide complete coverage when surveying potential nesting habitat on large cliff complexes, escarpments, or headwalls. Hovering for up to 30 seconds no closer than a horizontal distance of 20 meters from the cliff wall or observed nests may be necessary to discern nest type, document the site with a digital photograph of the nest, and if possible, allow for the observer to read patagial tags, count young, and age young in the nest (Hoechlin 1976). Confirmation of nest occupancy may be confirmed during later flights at a greater horizontal distance.

Re-nesting is rare, but Golden Eagles may fail at their first nest attempt, and move to, or create, an alternate nest site. Multiple visits to known or potential nesting habitat may be necessary to provide complete observation and coverage of habitat.

To inventory for the purpose of documenting presence/absence of Golden Eagles in potential habitat, at least 2 aerial observation flights of habitat are necessary. These flights will be spaced no closer than 30 days apart. Additional inventory work in the territory is not necessary after nests have been located where Golden Eagles are found incubating, or where eggs or young and number of eggs or young are noted. At this point, the observation effort should switch to monitoring of the known territory. The nest location should be documented (see territory/nest naming convention, pp. 21).

Inventory and monitoring flights will be based on local knowledge of known nesting chronologies for that latitude and elevation, and should be timed to be the most efficient to reduce the number of visits to the nest site. Flights may occur preferentially during a) late courtship, b) egg-laying though hatch, and/or c) when the young are between 20 – 51+ days old. Productivity surveys are best scheduled when the young are approximately 51+ days old (prior to fledging). Aerial visits at known nests may be augmented or replaced by ground observation (see below).

Other raptors or special status species may be observed during the flight, and should be recorded/reported. Coordination with state and federal agencies will be necessary when state or federally listed Threatened, Endangered or special status (species of concern, sensitive, etc.) species are present in the flight survey area (i.e. big-horn sheep, peregrine falcons, etc.).

Bighorn sheep share the same type of cliff complexes Golden Eagles use for nesting, and are hyper-sensitive to helicopters (Weyhausen 1980, Bleich et al. 1990). Specifically for bighorn sheep lambing areas, helicopter reconnaissance and surveys for Golden Eagles are not possible as these flights will induce unpermitted take during the lambing season; all helicopter survey work for Golden Eagles should be avoided in known lambing areas. Ground observation will be necessary for inventory of cliff complexes and monitoring of potential and known Golden Eagle territories in bighorn sheep lambing areas.

Most Golden Eagle respond to fixed wing aircraft and helicopters by remaining on their nests, and continuing incubation or roosting (DuBois 1984, McIntyre 1995). Perched birds may flush. During aerial surveys, deference to flying eagles should be given at all times. Flights at nest sites should be terminated and the helicopter should bank away and move to the next location if Golden Eagles appear to be disturbed; i.e. behavior that indicates the birds are agitated by the presence of the helicopter. In short, observers should obtain their data, and leave as soon as possible.

Any disturbance behavior observed should be noted so that consecutive aerial surveys would be sensitive to Golden Eagles at that location. Aerial reconnaissance to inventory/survey for potential habitat and additional visits at known nests may be augmented/replaced by ground observation from a safe distance (see below). Ground observation may be the recommended alternative to additional survey flights due to convenience or necessitated by other sensitive wildlife species. Follow-up ground observation from a safe distance may also be the recommended alternative for additional nest site monitoring.

Observers in helicopters have specific duties. At least two observers may be best for aerial surveys; one the lead observer, the other(s) supplement survey effort. One observer is assigned to record data on a tape recorder (unless the verbal interchange can be recorded on the helicopters internal communication system), and the other briefly records data on hard-copy and with digital photographs. Aerial observation routes should be recorded, downloaded, and reported using Global Positioning System track routes or applicable software programs. Observation locations and time-on-site should be recorded on applicable maps to ascertain coverage of cliff systems and other potentially suitable habitat.

Summary:

- Qualified observer(s) (as defined in section VIII).
  No closer than 10-20 meters from cliff; no farther than 200 meters from cliff (safety dependent).
- Close approach and extended hovering is allowed when there are no birds on the nest to allow observers to count eggs, dead young, or confirm nest failure.
- Multiple passes or 'bands' (i.e. back and forth at different elevations above ground level) of observation across cliff habitat may be necessary to achieve complete coverage in large cliff complex'.
- Occupied territories and current and alternative nest sites will be documented; nests 'decorated' with fresh branches should also be delineated.
- Once a nest with eggs, young, or an incubating adult has been located, there is no need to search for other nests within the territory.
- Minimal hovering time at known or potential nest; ca < 30 seconds.
- At least 2 surveys of previously unsurveyed habitat will be spaced at least 30 days apart.

VII.c. Ground Surveys

Ground surveys of potential habitat

Ground surveys for Golden Eagles in potential habitat may be achieved without aerial support, or may be used to augment extant aerial surveys. Ground surveys to detect Golden Eagle nests and the selected nest at known territories are effective in habitat where observation points are established to observe areas on cliffs, utility towers, or in trees suspected to be nesting habitat. As with aerial surveys, identification criteria for nesting habitat should take place in coordination with the Service, State or Tribal wildlife agencies, and raptor specialists.

Observation posts (OP) are established during initial reconnaissance of potential or known nest cliffs, and are established in locations that are far enough from the potential nest site to effectively observe the behavior of the adults (if present) without disturbing nesting behavior. Well-placed OPs provide unobstructed viewing of the potential nest location or of the area to be surveyed; including a broad panorama of the surrounding habitat. Multiple OPs or walking surveys may be necessary to observe potential nest sites. OPs located in front of, and below the potential nest cliff or tree are best. Placing OPs below the potential nest cliff reduces stress if an incubating adult may be present. The distance from an OP to the potential nest site may range from 300 – 1600 meters (latter represents extreme circumstances) from the cliff base to the observer, and generally no greater than 700 meters.

Golden Eagles may use alternative nests. Detection of previously unknown alternate nests and observation of all known alternative nests will become important if Golden Eagles fail in their initial nesting attempt, or are not observed at the probable nest location.

~~Ground monitoring; known territories~~

Monitoring to document nesting success at known territories may occur solely via ground observations. Observation of known territories should use the methodology described for ground monitoring of potential habitat (see section VIIc). Dates of all visits to the nesting territory will be recorded; date of confirmation of nesting failure will be key data for site specific and regional analysis.

Nesting outcomes

Fledging success will be determined via the observation of young that are at least 51 days of age, or are known to have fledged from the observed nest. If there is whitewash (Golden Eagle defecation) and a well worn nest, young were previously observed in the nest to be > 4 weeks old during a previous visit, and the young would have been > 51 days old at the time of the visit, and no dead young are found after a thorough ground search, the nesting attempt can be deemed successful.

Nesting failure occurs when a nest where eggs were laid or where incubation behavior was observed fails to have any young reach 51 days of age. If necessary, nesting failure will be confirmed by using a spotting scope to view the nest to determine if dead young are observed. Nesting failures may also be determined if observations of the nest prior to the projected fledge date yields no young or fledglings where eggs or young were previously observed. In these instances observation periods should last 4 hours (consecutively), or are confirmed by aerial survey. If dead young are observed in the nest (i.e. all young are dead), monitoring efforts may cease. Nest failures may also be confirmed by an approach (walk-in) to the nest no more than 4 weeks after fledging was scheduled to occur. Observers will look for dead chicks at the base of the nest cliff or tree, where access is reasonable and safe.

Observers must document the criteria they use to conclude that success or failure occurred.

Summary

- Observation posts for monitoring known territories will be no closer than 300 meters for extended observations, and generally no further than 700 meters, where terrain allows. Maximum OP distance would be 1600 meters.

- To inventory and determine occupancy of cliff systems, there will be *at least* 2 observation periods per season. To determine fledging success, additional observations may (or may not) be necessary.
    - Observation periods will last at least 4 hours for known nest sites, or until territory occupancy can be confirmed.
    - Observation periods will last for at least 4 hours per 1.6 km of cliff system, based from the center point of that cliff complex.
    - Observation periods will be at least 30 days apart for monitoring efforts.
- To collect monitoring data at a known nest territory, there will be at least 2 observation periods per season.
    - Observation periods from ground observation points will last at least 4 hours for known nest sites or until nesting chronology can be confirmed per visit. Observation periods will be at least 30 days apart.

VIII. Observer qualifications

Surveyor experience affects the results of protocol-driven raptor surveys. All surveyors/observers should have the equivalent of 2 seasons of intensive experience conducting survey and monitoring of Golden Eagle and/or cliff dwelling raptors. That experience may include banding, intensive behavioral monitoring, or protocol-driven survey work. Experience should be detailed and confirmed with references, and provided to action and regulatory agencies. All surveyors should be well-versed with raptor research study design and Golden Eagle behavior and sign, including nests, perches, mutes, feathers, prey remains, flight patterns, disturbance behavior, vocalizations, age determination, etc. **Aerial surveys will be conducted by raptor specialists who have at least 3 field seasons experience in helicopter-borne raptor surveys around cliff ecosystems.**

In lieu of limited or no Golden Eagle experience, ground surveyors should attend at least a 2-day Golden Eagle training session convened with classroom and field components; trainers will be designated by the USFWS/USGS. Inexperienced or limited experience surveyors will be mentored by Golden Eagle specialists for at least 1-2 field seasons, depending on their experience level, and should assist with the preparation of at least 3 surveys and reports over at least 3 years. A Golden Eagle specialist is defined as a biologist or ecologist with 5 or more years of Golden Eagle or cliff dwelling raptor research/survey experience, possession of state/federal permit allowing capture, handling, and/or translocation of Golden Eagles and/or

cliff dwelling raptors; and/or relevant research on raptors published in the peer reviewed literature.

IX. Documentation and accepted notation of territory/nest site and area surveyed

Data for each territory/nest site(s) and area visited will be reported annually to the applicable regional office of the USFWS Division of Migratory Bird Management for collation into a national database.

Minimum data collected at known Golden Eagle territories

Observation of potential sites and known nest territories will produce data helpful to determine territory occupancy, productivity, and fate of the nesting attempt. Each observation and all site specific data collected should include at least;

a) date of observation,
b) time of observation(s),
c) weather during observation,
d) duration of observation,
e) name of observer(s),
f) location of observation,
g) description of observation.

Data collected during inventory and monitoring will include (at least) the following:

- Territory status [Unknown; Vacant; Occupied-1 eagle; Occupied-2 eagles- laying or non-laying; Breeding successful (chick observed to be at least +51 days-fledging), Breeding unsuccessful (failed-nesting attempt failed after eggs were laid)].
- Nest location (decimal degree lat/long or UTM).
- Nest elevation.
- Age class of Golden Eagles observed.
- Document nesting chronology;
    - Date clutch complete (estimated). Describe incubation behavior observed to derive this date, and/or use backdating from known nestling age).
    - Hatch date (estimated from age of nestlings).
    - Fledge date (known or estimated; see nesting outcomes, pp. 18).
    - Date nesting failure first observed and/or confirmed.

- Number of young at each visit and at >51 days of age.
- Digital photographs; a) landscape view of area inventoried, b) landscape view of territory, and c) nest(s).
- Substrate upon which the nest is placed (tree species, cliff, or structure).

Additional data that can be collected include (but are not limited to):

- Presence or absence of bands (USGS and VID), patagial tags (number and color), or telemetry unit.
- Forage location (if known).
- Prey items noted (if discerned).
- Height of nest on cliff or in tree, and description of technique used to estimate height.
- Species of tree, type of rock, or type of structure used to support the nest.
- Overall cliff or tree height, and description of technique used to estimate height.
- Nest aspect.
- Other nesting raptors present nearby.

Each area surveyed under the requirements of this protocol, including surveyed habitat, occupied nesting territory, historical territory, and suspected/alternative nests will be recorded in a standardized manner to allow local, regional, and national data analysis.

Recommended Golden Eagle Territory/site naming convention:

XX^1-XXX^2-$XXXXX$/XX^3-XXX^4-XX^5 Territory name

XX^1 = State (two letter alpha)

XXX^2 = County (three letter alpha)

XX^3= USGS Quad [five numeric/two letter alpha] (when the territory straddles adjacent quad maps, the quad in which the first nest was found will be used to describe the territory; XX^5 is used to document the locations of alternate nests within a territory).

XXX[4]=Assigned Territory number within USGS quad (three numeric)

XX[5]=Assigned Nest number within territory in instances of alternate nests (two numeric)

Site name=traditional site name, or if new, use local naming convention (e.g. Upper fork Amundsen Creek, Fort Peck flatland, Farmer Jane's back 40).

Example CA-KER-38512/DG-03-02 Abbot Creek

X. Additional considerations

This interim document primarily contains methods for inventorying and monitoring at nest sites, but the prohibitions against take and the new regulations apply at nest sites and foraging areas, as well as during migration and other non-breeding times. The Service will develop or adopt recommendations for surveys applicable to non-nesting in other documents.

Suitable foraging habitat

Golden Eagles forage close to and far from their nests, i.e. < 6 km from the center of their territories, but have been observed to move 9 km from the center of their territories in favorable habitat (McGrady et al. 2002). These distances may be further in xeric habitat.

Suitable wintering habitat

During winter, Golden Eagles are found throughout the contiguous United States. Inventories for wintering Golden Eagles will encompass all habitat where Golden Eagles have been known to nest, roost, and forage. Refer to Wheeler (2003, 2007) for maps elucidating suitable wintering range.

Winter surveys

Survey information gathered during the non-breeding period is needed to identify foraging areas and determine numerical estimates of use by Golden Eagles. Presence of Golden Eagles during winter surveys does not necessarily mean that breeding individuals are present; however follow-up surveys during the breeding season are necessary to denote occupancy at suspected or known territories.

Migration surveys

The location of migration routes or areas in relation to a proposal that are likely to take Golden Eagles through injury or mortality may have critical implications. Therefore, evaluations should assess whether migratory or transient Golden Eagles are likely to be present during the construction and the life of the project. Other factors to consider include numbers of Golden Eagles moving through the project area, movement patterns (including a three-dimensional spatial analysis), time of day, and seasonal patterns. In the case of wind development, surveys will need to identify the locations of migration routes and movements during migration in relation to proposed turbines and rotor-swept area.

XI. Acknowledgments.

The authors are indebted to the expertise, experience, effort and kindness expended on all phases of this protocol by Dr. Mark Fuller (USGS), Mike Kochert (USGS Emeritis), and Karen Steenhof (USGS Retired). We greatly appreciate the time they took to review multiple drafts, and provide sound advice and guidance where necessary regarding all aspects of Golden Eagle inventory and monitoring. Robert Murphy's comments on earlier drafts were also appreciated. We also appreciated Peter Bloom's input and good humor regarding his observations of Golden Eagle natural history and monitoring, and the cover photograph of a Golden Eagle taken from beneath a calf carcass while he was in a southern California pit trap.

XIII Glossary

Action agency – an agency or entity authorizing an action or plan, or providing funding for actions and plans.

Active nest (from the regulations) — a Golden Eagle nest characterized by the presence of any adult, egg, or dependent young at the nest in the past 10 consecutive days immediately prior to, and including, at present. Applies only to applications for permits to take eagle nests.

Breeding home ranges - the spatial extent or outside boundary of the movement of individuals from Golden Eagle pairs during the course of everyday activities during the breeding season.

Inactive nest (from the regulations) — a Golden Eagle nest that is not currently being used by eagles as determined by the continuing absence of any adult, egg, or dependent young at the nest for at least 10 consecutive days immediately prior to, and including, at present. An inactive nest may become active again and remains protected under the Eagle Act.

Inventory –systematic observations of the numbers, locations, and distribution of Golden Eagles and eagle resources such as suitable habitat and prey in an area.

Local area population — the population within the average natal dispersal distance of the nest or nests under consideration (43 miles for bald eagles, 140 miles for golden eagles). Effects to the local area population are one consideration in the evaluation of the direct, indirect, and cumulative effects of take, and the mitigation for such take, under eagle take permits.

Migration corridors - the routes or areas where eagles may concentrate during migration. Golden Eagles begin migrating across a broad front, but tend to concentrate along leading lines (geographical features such mountain ridges) as they move between geographic locations. Golden Eagles are observed in largest numbers along north-south oriented mountain ranges where they soar on mountain updrafts. The species typically avoids lengthy water-crossings. In North America, migrating Golden Eagles concentrate along the Appalachian Mountains in the East and Rocky Mountains in the West.

Management agency - see Action Agency.

Monitoring - inventories over intervals of time (repeated observations), using comparable methods so that changes can be identified. Monitoring includes analysis of inventory data or measurements to evaluate change within or to defined metrics. Monitoring also includes repeated observations of a known nesting territory.

Occupied Nests - those nests which are used for breeding in the current year by a pair. Presence of raptors (adults, eggs, or young), freshly molted feathers or plucked down, or

current years' mute remains (whitewash) suggest site occupancy. Additionally, for the purposes of these guidelines, all breeding sites within a breeding territory are deemed occupied while raptors are demonstrating pair bonding activities and developing an affinity to a given area. If this culminates in an individual nest being selected for use by a breeding pair, then the other nests in the nesting territory will no longer be considered occupied for the current breeding season. A nest site remains occupied throughout the periods of initial courtship and pair-bonding, egg laying, incubation, brooding, fledging, and post-fledging dependency of the young.

Unoccupied Nests - those nests not selected by raptors for use in the current nesting season. Nests would also be considered unoccupied for the non-breeding period of the year. The exact point in time when a nest becomes unoccupied should be determined by a qualified wildlife biologist based upon observations and that the breeding season has advanced such that nesting is not expected. Inactivity at a nest site or territory does not necessarily indicate permanent abandonment.

Productivity — the mean number of individuals fledged per occupied nest annually.

Survey –is used when referring to inventory and monitoring combined.

EXECUTIVE PROJECT SUMMARY

This document reports on findings of the Phase 1 and Phase 2 surveys for Golden Eagles within 4 miles of the Final Environmentally Superior Southern Route of the San Diego Gas & Electric Sunrise Powerlink Project alignment. Information from these surveys will be used in avoiding and reducing the potential for inadvertent impacts on Golden Eagles during the nesting season, including compliance with Mitigation Measure B-7h - Implement Appropriate Avoidance/Minimization Strategies for Eagle Nests. This mitigation measure is outlined in Appendix 12 of the Sunrise Powerlink Project's Environmental Impact Report/Environmental Impact Statement (California Public Utilities Commission and U.S. Department of the Interior Bureau of Land Management 2008) and the associated Biological Opinion (U.S. Fish and Wildlife Service 2009). These surveys comply with the U.S. Fish and Wildlife Service recommendations. The Wildlife Research Institute, Inc. has conducted Golden Eagle population studies in Southern California for the past 22 years and has utilized this historic data to identify and survey 19 Golden Eagle territories that fell within the recommended guidelines. Surveys for this project were conducted both by ground and helicopter to confirm activity, occupancy, breeding status of the pairs, and fledging success of the Golden Eagles. Ground surveys started in January 2010 and continued through early April 2010; helicopter surveys started on March 30, 2010 and continued with several flights through May 14, 2010. Nineteen territories were checked and 9 were confirmed to be active during 2010; 2 additional territories were considered possibly active based on nest site evidence, and 8 appeared to be inactive. Five of the active territories were seen with incubating females on the nests during the surveys. In total, 24 Golden Eagle adults and nestlings were observed in addition to 9 other species (i.e., Antelope Ground Squirrels, American Kestrels, Bighorn Sheep, Common Ravens, Great Horned Owls, Jackrabbits, Prairie Falcons, Red-tailed Hawks, and Turkey Vultures) totaling 95 wildlife documentations. All sightings have been documented with GPS locations and recorded on the attached maps and tables as recommended in the USFWS Interim Golden Eagle Technical Guidance: Inventory and Monitoring Protocols; and Other Recommendations in Support of Golden Eagle Management and Permit Issuance (Pagel et al. 2010).

PROJECT SCOPE

The survey work reported here was conducted to record and report occupancy (Phase 1) and productivity (Phase 2) of Golden Eagles (*Aquila chrysaetos*) on and around the San Diego Gas & Electric (SDG&E) Sunrise Powerlink Project area, including a 4-mile spatial buffer from the proposed project alignment to allow for proper data interpretation of occupied territories, a U.S. Fish and Wildlife Service (USFWS) recommendation (Pagel et al. 2010).

The Sunrise Powerlink is an approximately 118-mile-long 230kV/500kV transmission line that will traverse from SDG&E's Imperial Valley Substation near El Centro, Imperial County, to SDG&E's Sycamore Canyon Substation on Marine Corps Air Station Miramar in San Diego County. One new substation (Suncrest Substation) will be constructed south of Interstate 8 and west of Japatul Valley Road in the Bell Bluff area to convert the line from 500kV to 230kV. Results of these surveys will be used by SDG&E to adjust construction activities, including helicopter flights, to avoid and reduce the potential for inadvertent impacts on Golden Eagles during the nesting season. In addition to the USFWS's existing protocol's for avoiding take of Golden Eagles under the Bald and Golden Eagle Protection Act, the Sunrise Powerlink Project is obligated to comply with Mitigation Measure B-7h, which prohibits construction or maintenance activities within 4,000 feet of an eagle nest during the eagle breeding season (December through June).

PROJECT BACKGROUND

Golden Eagles respond to environmental changes in order to survive and reproduction in Golden Eagles, as in many predators, is regulated by prey species abundance. Since 1998, Western North America has been in a prolonged drought and this has affected many species including Golden Eagles (Bittner et al. 2003). Jackrabbits, an important prey species for Golden Eagles, have also declined (L. LaPre, Bureau of Land Management [BLM] and M. Jorgenson, California State Parks pers.com.). Golden Eagle adults have persevered but reproduction rates have dropped to as low as 12% in some regions, such as the Mojave and Sonoran Deserts of the American Southwest (Bittner et al. 2003). As indicated by Figure 1, studies done by the Wildlife Research Institute (WRI) for the BLM have confirmed these unusually low reproductive levels (WRI 2002, 2003, 2009).

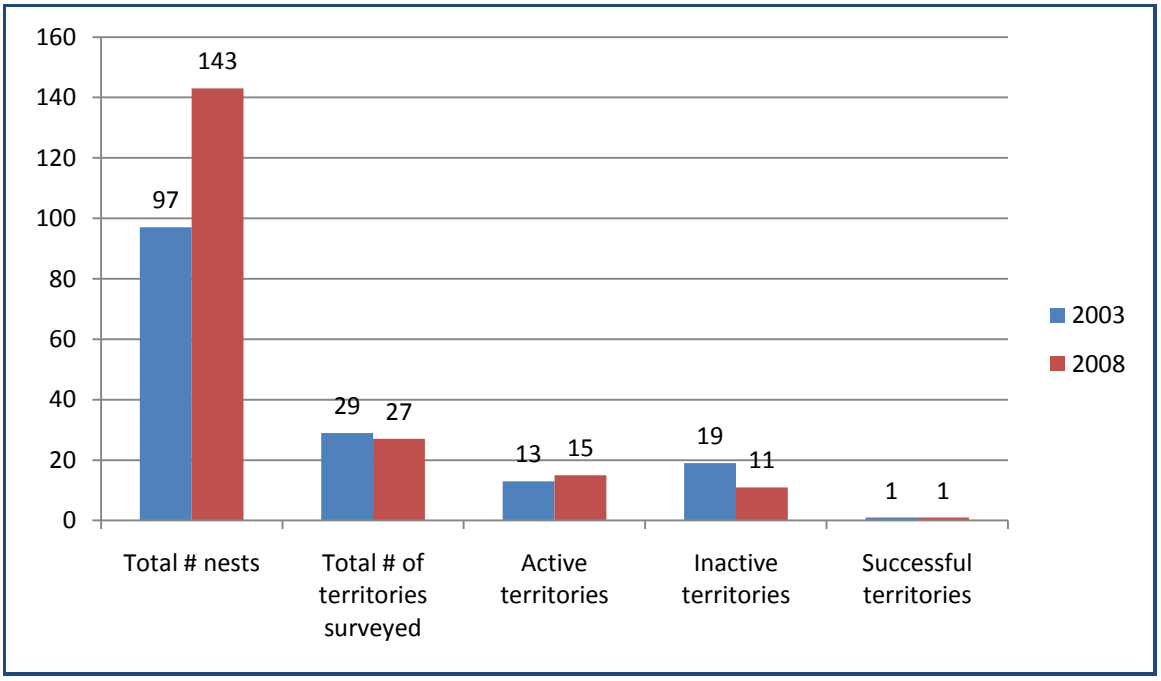

Figure 1. WRI 2003 and 2008 Western Mojave Desert Golden Eagle Data from BLM Studies.

Eagles are large predatory birds with up to 7-foot wingspans and raising young takes a large investment of time and energy. Breeding in Southern California starts in January, nest building and egg laying in February to March, and hatching and raising the young eagles occur from April through June. Once the young eagles are flying on their own, the adult eagles will continue to feed them and teach them to hunt until late November. They then repeat the nesting process. This huge investment of time and energy on the part of the adults, just to raise one or two young, causes some pairs to take a year off from breeding once in awhile even when food is abundant.

WRI has learned, based on 22 years of helicopter and ground studies on Golden Eagles, that an initial helicopter survey can successfully identify 80 to 90% of the Golden Eagle territories in a given area. Follow-up ground and helicopter surveys have indicated that some nests, and even some pairs, might be missed during the first survey. Second surveys are conducted to determine reproductive success but can also identify successful nesting attempts that were missed during initial surveys as well as reveal fledging success.

GOLDEN EAGLE SURVEY AREA

The Sunrise alignment is approximately 118 miles long, traverses from the SDG&E substation near El Centro (Imperial Valley Substation) in Imperial County to the substation on Miramar (Sycamore Canyon Substation) and crosses over BLM, private, U.S. Forest Service (USFS), County of San Diego, City of San Diego, and Department of Defense (Miramar) land.

The Golden Eagle survey area encompasses the SDG&E Sunrise Powerlink Project alignment plus a 4-mile spatial buffer on either side of the linear project. In addition to the above lands, the Golden Eagle survey area includes parts of the Anza-Borrego State Park and several Indian reservations.

Figure 2. Vicinity Map.

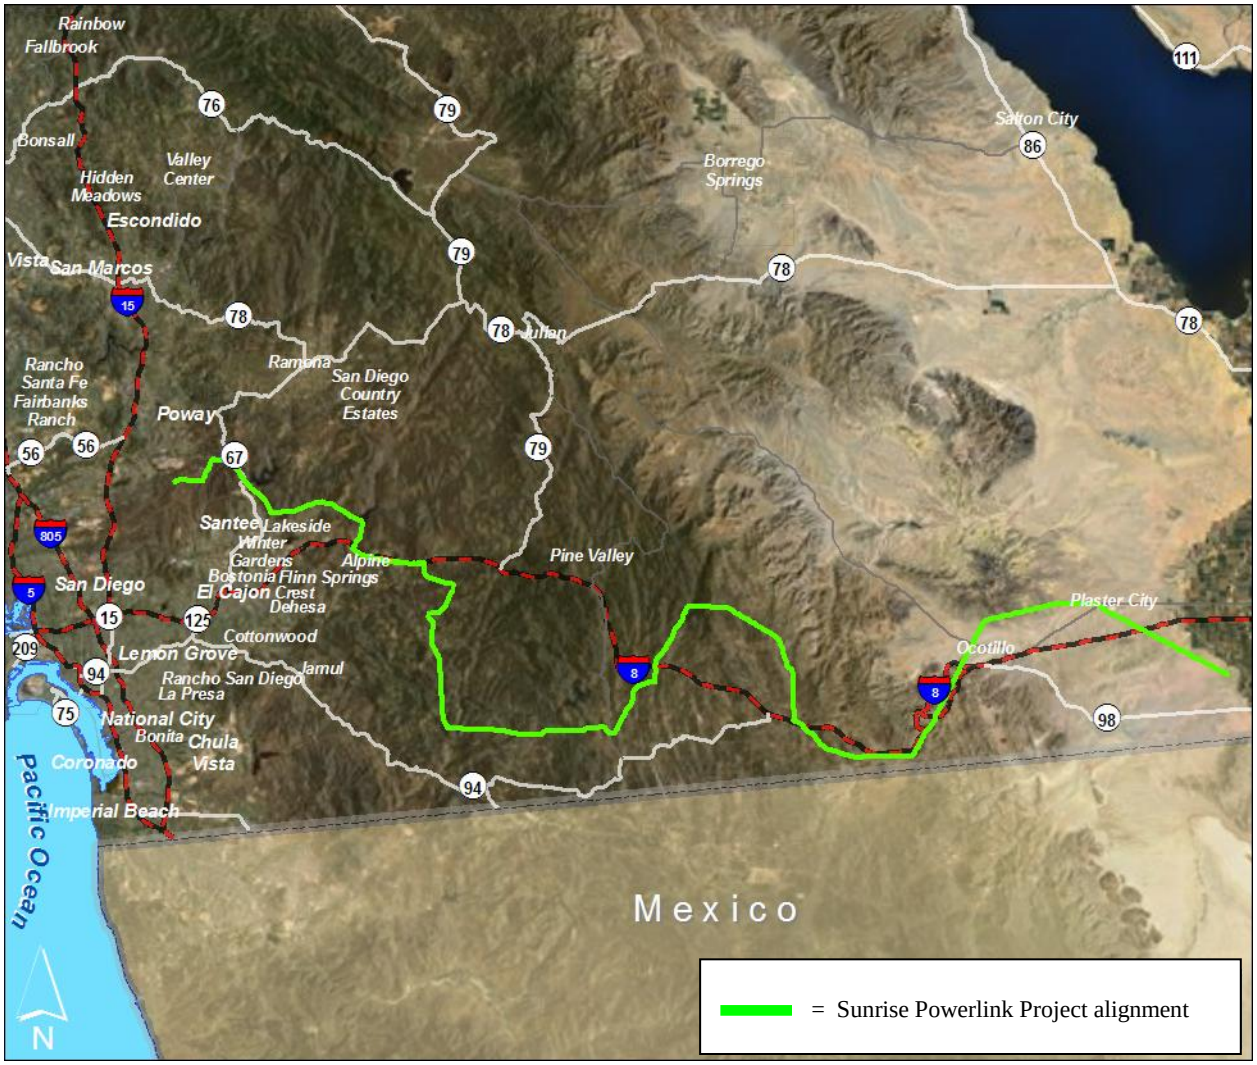

Figure 3. Project Location Map.

General alignment of Sunrise Powerlink Project Area. The surveys of this study area covered a 4-mile spatial buffer along the outer boundary of the project area.

PHASE 1 REPORT

ABSTRACT – PHASE 1 SURVEYS

This section reports on findings of the **Phase 1** surveys conducted in San Diego County, California, to record and report occupancy for Golden Eagles within 4 miles of the Sunrise Powerlink project boundary in order to comply with the U.S. Fish and Wildlife Service recommendations. Based on historical knowledge and 22 years of ongoing Golden Eagle research by the Wildlife Research Institute in San Diego County, California, 18 Golden Eagle territories were initially identified that surrounded the project boundary including the 4-mile spatial buffer. These territories were surveyed by Wildlife Research Institute biologists via helicopter and ground. Additional Phase 1 surveys of these territories occurred during annual research and monitoring conducted during January and February of 2010 by the Wildlife Research Institute in San Diego County. A total of 42 Golden Eagle nests were observed, 2 of which constituted an additional territory in the East Coyote Mountains, for a total of 19 Golden Eagle territories. Of the 19 territories, 9 were active, 2 possibly active, and 8 inactive in the 2010 breeding season; 5 were found with incubating females. Besides 24 Golden Eagles, 9 other species were seen (i.e., Antelope Ground Squirrels, American Kestrel, Bighorn Sheep, Common Ravens, Great Horned Owls, Jackrabbits, Prairie Falcons, Red-tailed Hawks, and Turkey Vultures) totaling 95 wildlife documentations. All sightings have been documented with GPS locations and recorded on the attached maps and tables as recommended in the USFWS Interim Golden Eagle Technical Guidance: Inventory and Monitoring Protocols; and Other Recommendations in Support of Golden Eagle Management and Permit Issuance (Pagel et al. 2010).

METHODS AND CONSTRAINTS

Methods

The study area encompasses part of Southeast San Diego County, an area that has been part of the WRI's 22 year-long Golden Eagle study initiated in 1988. All territories have a known history to WRI and we utilized that data to improve the accuracy of this study. WRI also houses an archive of data dating back to the late 1800's from other researchers who studied Golden Eagles in and around San Diego County.

We contacted Dr. Larry LaPre, of the BLM, to request available historic records or reports of Golden Eagle nesting activity and/or sightings in the project area. WRI utilized the information provided by Dr. LaPre to improve our survey focus.

It should be noted that all surveying and reporting complies with the current U.S. Fish and Wildlife Service Interim Golden Eagle Inventory and Monitoring Protocols released in 2010 (Pagel et al. 2010).

Survey

We used Hughes-500 helicopters that provided seating for three investigators including 2 Golden Eagle biologists, a Bighorn Sheep biologist, and the pilot.

On March 30, 2010, April 1,2,3, and 25, 2010, WRI conducted helicopter and ground surveys (Figure 4) for the target species, Golden Eagle, specifically around the Sunrise Powerlink project area including the 4-mile spatial buffer. We spent approximately 75 person-hours of actual aerial and ground observations during the surveys for this phase. We concentrated on known or historically documented Golden Eagle territories that fell within the Sunrise Powerlink project area and 4-mile spatial buffer.

It should also be noted that, in addition to scheduled Phase 1 surveys, WRI periodically monitored active nest sites around the Sunrise Powerlink project area during our own ongoing research of Golden Eagle territories in San Diego County, California.

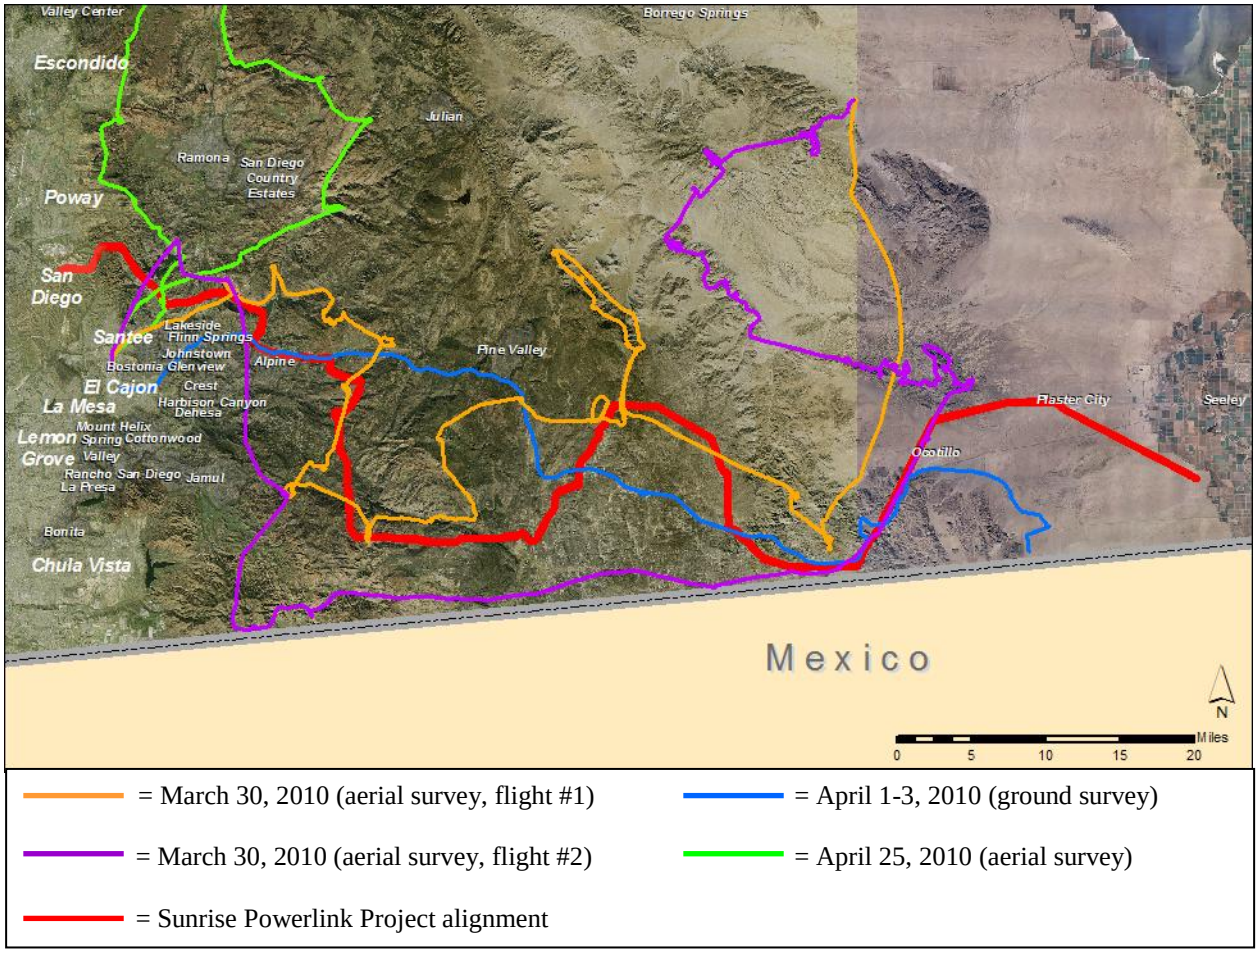

Figure 4. Phase 1 Study Area with Flight Paths and Sunrise Powerlink Project Alignment.

GPS

Nest site and other location-specific data were determined and documented using hand-held GPS units (Garmin Map60GSx). A sequential number was assigned to each observation that corresponded to the GPS waypoint. Waypoints were recorded using the UTM grid in the WGS 84 Datum. GPS was also used to track our survey routes (Figure 4). Handwritten notes were also taken that documented species and corresponded to each GPS waypoint.

Data

We photographed all active Golden Eagle nests, some other raptor nests, representations of numerous inactive Golden Eagle nest sites, and significant other wildlife species observed. The following data were also specifically collected and are on file at WRI but may not be included in all reports (Appendix A):

- Species
- Number of nests/alternative nests observed
- Condition of each nest and whether or not it was active

- Nest aspect
- Nest elevation
- Nest GPS coordinates
- Nest substrate (cliff, transmission tower, etc.)
- Age class of Golden Eagles and other species if determinable
- Behavior of species observed.

It should be noted that Red-tailed Hawks (*Buteo jamaicensis*) in particular, as well as other raptors such as Prairie Falcons (*Falco mexicanus*), sometimes utilize Golden Eagle nests for their own nesting, something observed during surveys for this project.

Constraints

In that these were diurnal surveys focused on Golden Eagles, we were less likely to observe nocturnal and crepuscular raptors (i.e., owls). Aerial surveys also tend to under-represent the smaller species, like the American kestrel (*Falco sparverius*) and burrowing owl (*Athene cunicularia*).

The release of the Interim Golden Eagle Technical Guidance in February 2010 and subsequent contracts being finalized in March 2010 resulted in survey flights being scheduled late in the Golden Eagle breeding season. Initiating surveys this late in the season may have resulted in missed observations of adult eagles on territory earlier in the year (December 2009 - February 2010) that attempted to nest but failed or that did not attempt to produce young.

RESULTS

Golden Eagles

We observed a total of 42 Golden Eagle nests in the 19 Golden Eagle territories surveyed. The nests were in various conditions and some may not have been used for many years. It is important to note that many of the nests are alternative nest sites for the same territory. We documented 9 of these territories to be active, 2 to be possibly active, and 8 inactive this year; all 8 of these inactive territories are known to have been active within the last 2-3 years (Figure 5) based on Wildlife Research Institute's Golden Eagle banding activities. Five of the active Golden Eagle territories (Barrett/Echo Mountain, Canebrake, Iron Mountain, Lake Moreno/ Moreno Butte, and San Vicente) were found with incubating females. We returned in May 2010 to conduct Phase 2 of the survey and to document if the incubating pairs were successful and also to document if any of the other active territories successfully produced young from nests not initially found.

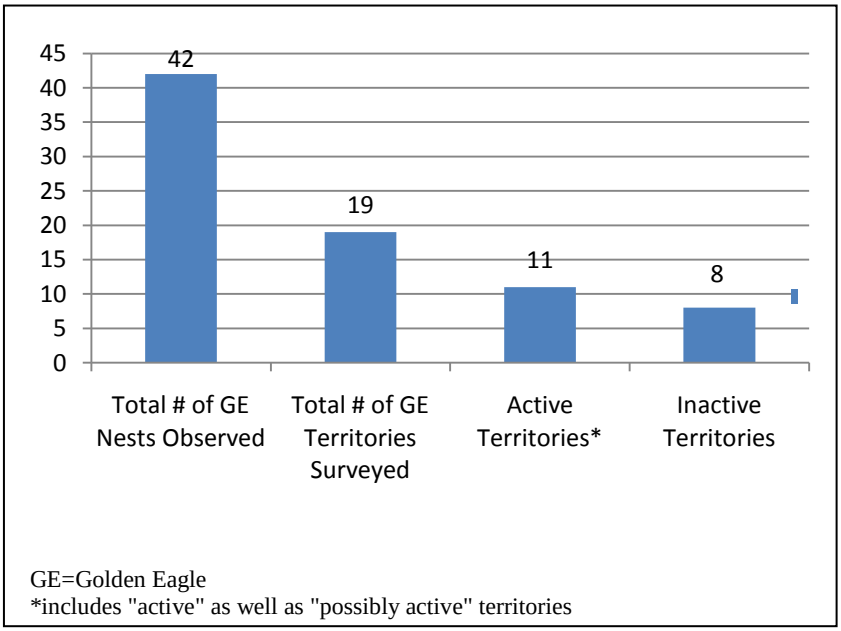

Figure 5. Phase 1 2010 Golden Eagle Territory Data for the Sunrise Powerlink Project.

Based on the USFWS Interim Golden Eagle Guidelines (Pagel et al. 2010), all wildlife observations are documented below in Table 1.

Species	Barrett/Echo Mtn	Canebrake	Carrizo Gorge	Coyote Mtns - East	Coyote Mtns - West	El Cajon	Fosters	Hauser Cyn	Iron Mtn	Lyons Pk	Moreno Butte/ Lake Moreno	Mountain Springs	Rock Mtn	San Vicente	Table Mtn	Thing Valley	Viejas Mtn	Totals

Table 1. Phase 1 – All Wildlife Observed During Phase 1 Surveys.

On the following two pages, Table 2 lists the waypoint identification number for each Golden Eagle nest identified, the status of Golden Eagle nest activity (i.e., whether or not it was active and whether an incubating female was observed), the territory name (incorporating the state, county, and U.S. Geological Survey [USGS] Quad; the USFWS recommended naming convention), and the geographical territory name where the nest was located. Active, and possibly active, territories are highlighted in yellow.

SURVEY MAPS BY GOLDEN EAGLE TERRITORY

All Golden Eagle Territories Surrounding the Sunrise Powerlink Project Area

Overview map of all Golden Eagle territories, with an approximate 5-mile Golden Eagle territory radius (as suggested by USFWS), surrounding the Sunrise Powerlink project area in San Diego County, California (Figure 6).

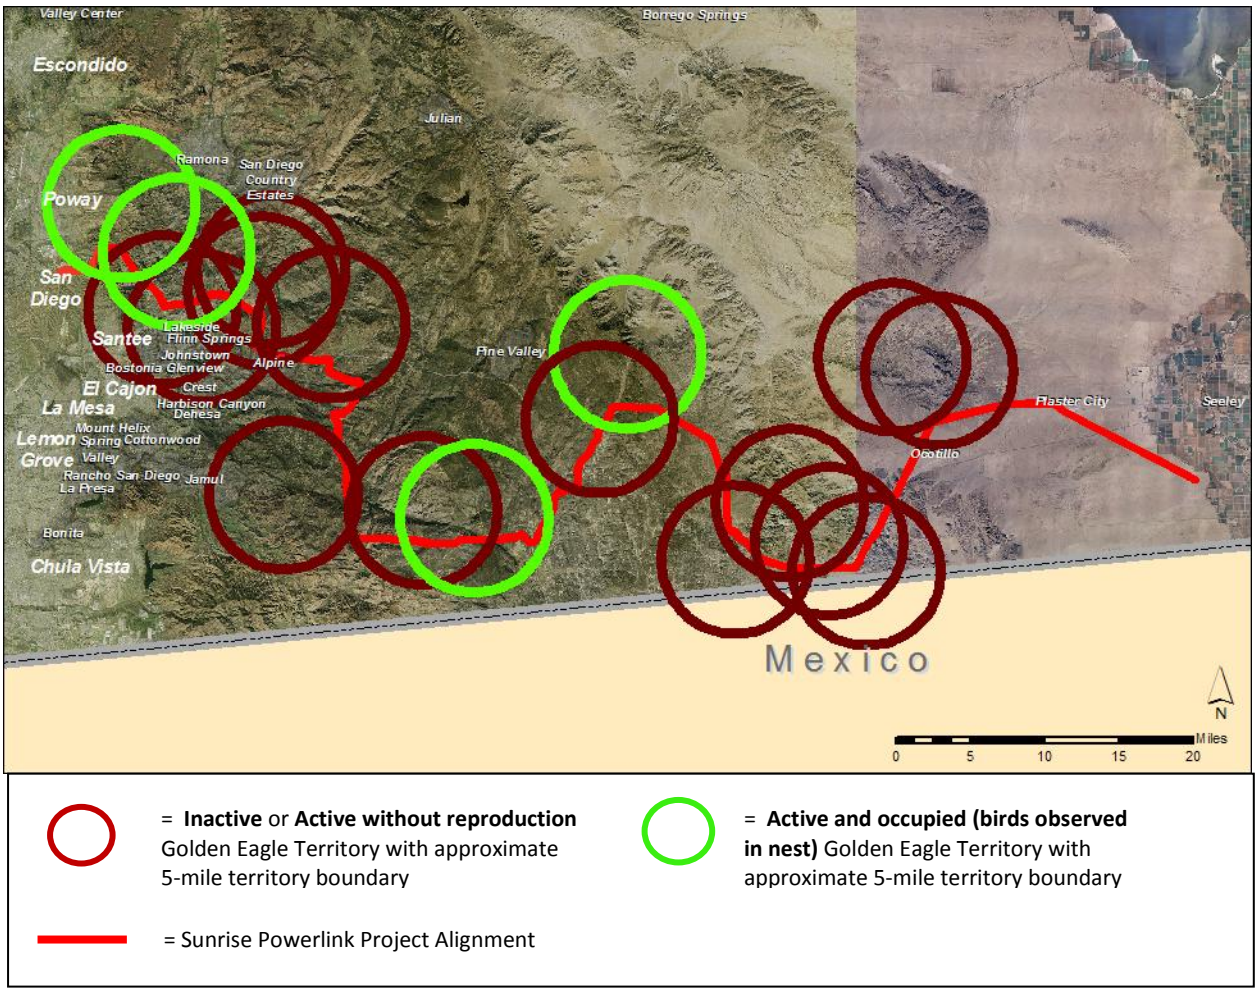

Figure 6. Overview Map of all Golden Eagle Territories Surveyed During Phase 1.

Legend for Survey Maps

Figure 7 provides a description of the waypoint labels and abbreviations noted on the following survey maps.

Map Legend	
A50GESN-1	observation ID
A =	trip ID
50 =	waypoint ID
GE =	Golden Eagle
SN =	stick nest
1 =	one bird/animal present
AG =	Antelope Ground Squirrel
AK =	American Kestrel
BS =	Bighorn Sheep
CR =	Common Raven
GE =	**Golden Eagle**
GO =	Great Horned Owl
JR =	Jackrabbit
PR =	Prairie Falcon
RT =	Red-tailed Hawk
SN =	stick nest
TV =	Turkey Vulture
U =	unidentified
Survey Paths	
=	March 30, 2010 (helicopter)
=	March 30, 2010 (helicopter)
=	April 1-3, 2010 (ground)
=	April 25, 2010 (helicopter)
=	Occupied territory with an approximate 5-mile radius
=	Inactive or active without reproduction territory with an approximate 5-mile radius

Figure 7. Survey Map Legend for Phase 1 Golden Eagle Territory Maps.

Barrett / Echo Mountain

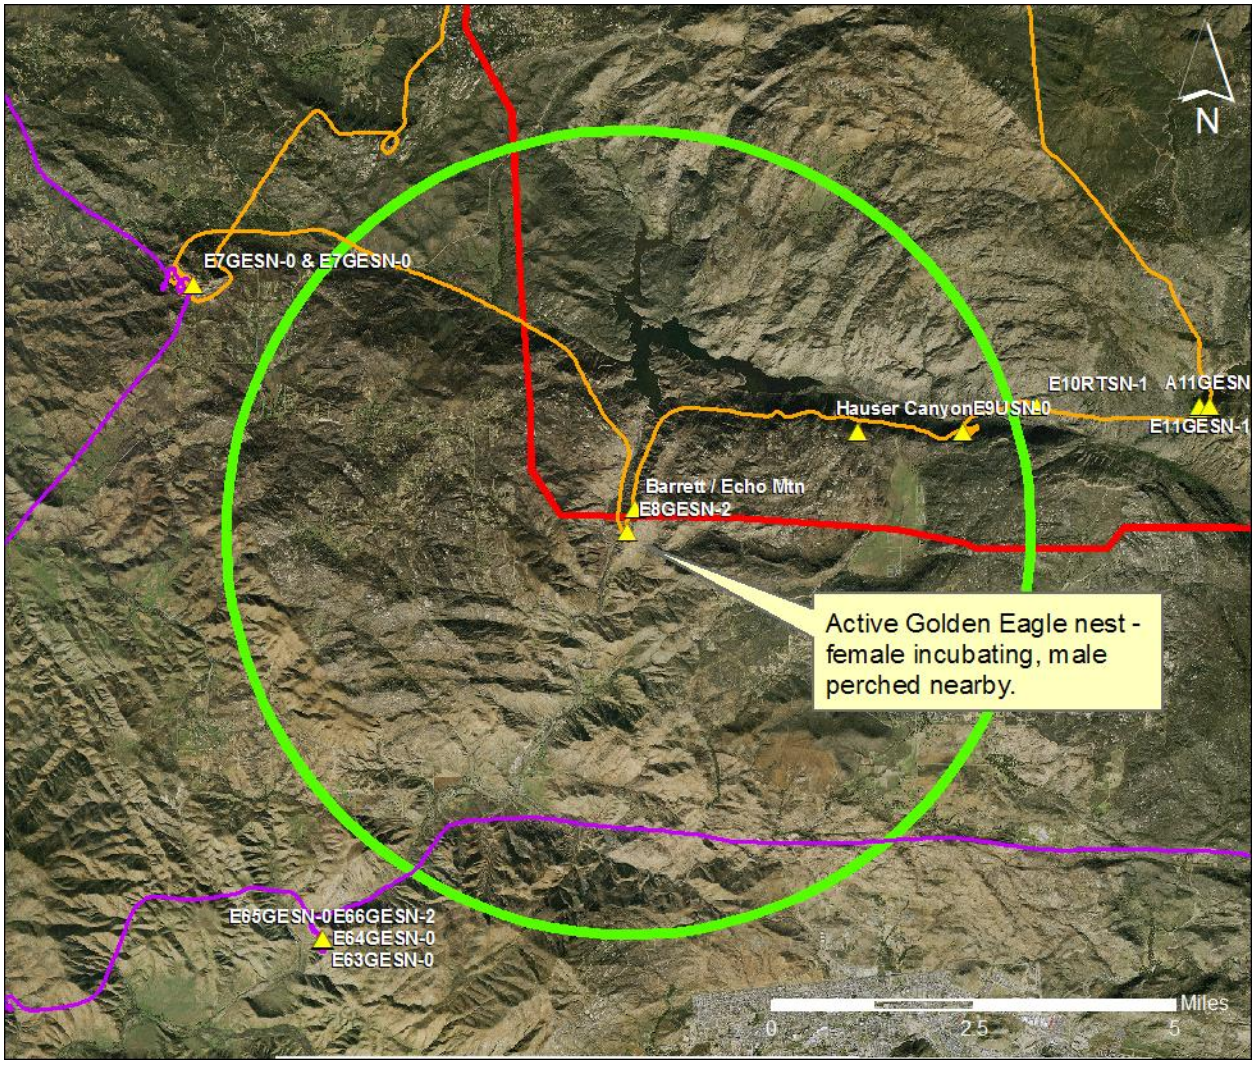

Figure 8. Barrett / Echo Mountain.

Barrett / Echo Mountain, active and occupied territory. All waypoints for species and nests observed, the helicopter flight paths, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

Two Golden Eagles were observed; the female was incubating and the male was perched nearby.

Barrett / Echo Mountain

An active Golden Eagle nest (E8GESN-2); good condition with incubating female. Male perched nearby.

Bell Bluff

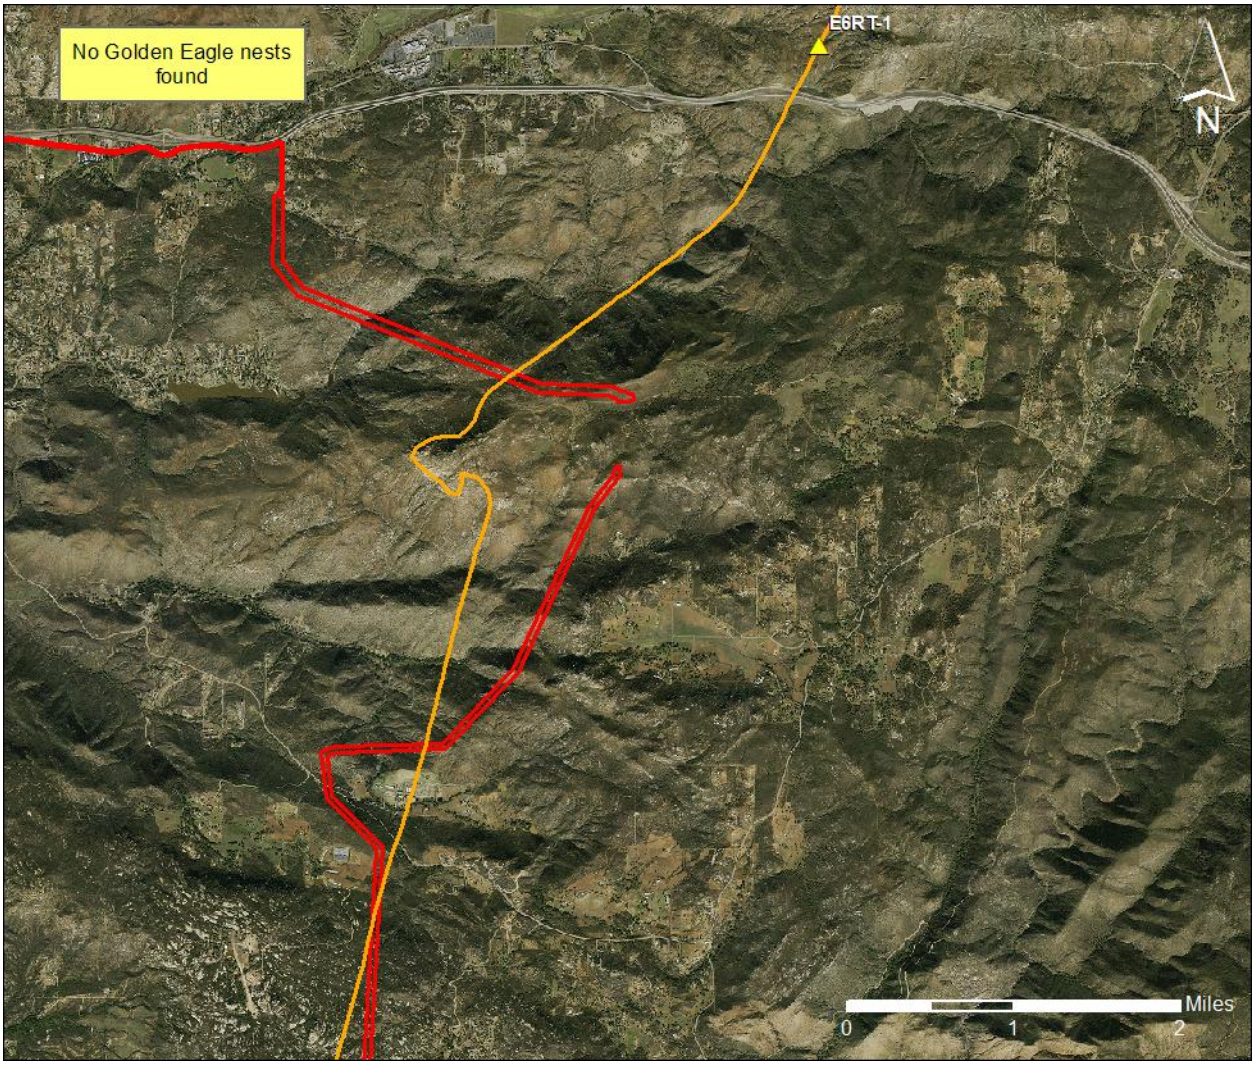

Figure 9. Bell Bluff.

Bell Bluff, inactive territory. All waypoints for species and nests observed, Project alignment, and the helicopter flight path are provided.

No Golden Eagle nests have been rediscovered in this territory since the recent (2003 and 2007) fires in San Diego County destroyed the nests previously used by the pair in this area. The eagles continue to be observed in this territory although no reproduction has been noted in the last several years.

Boundary Peak

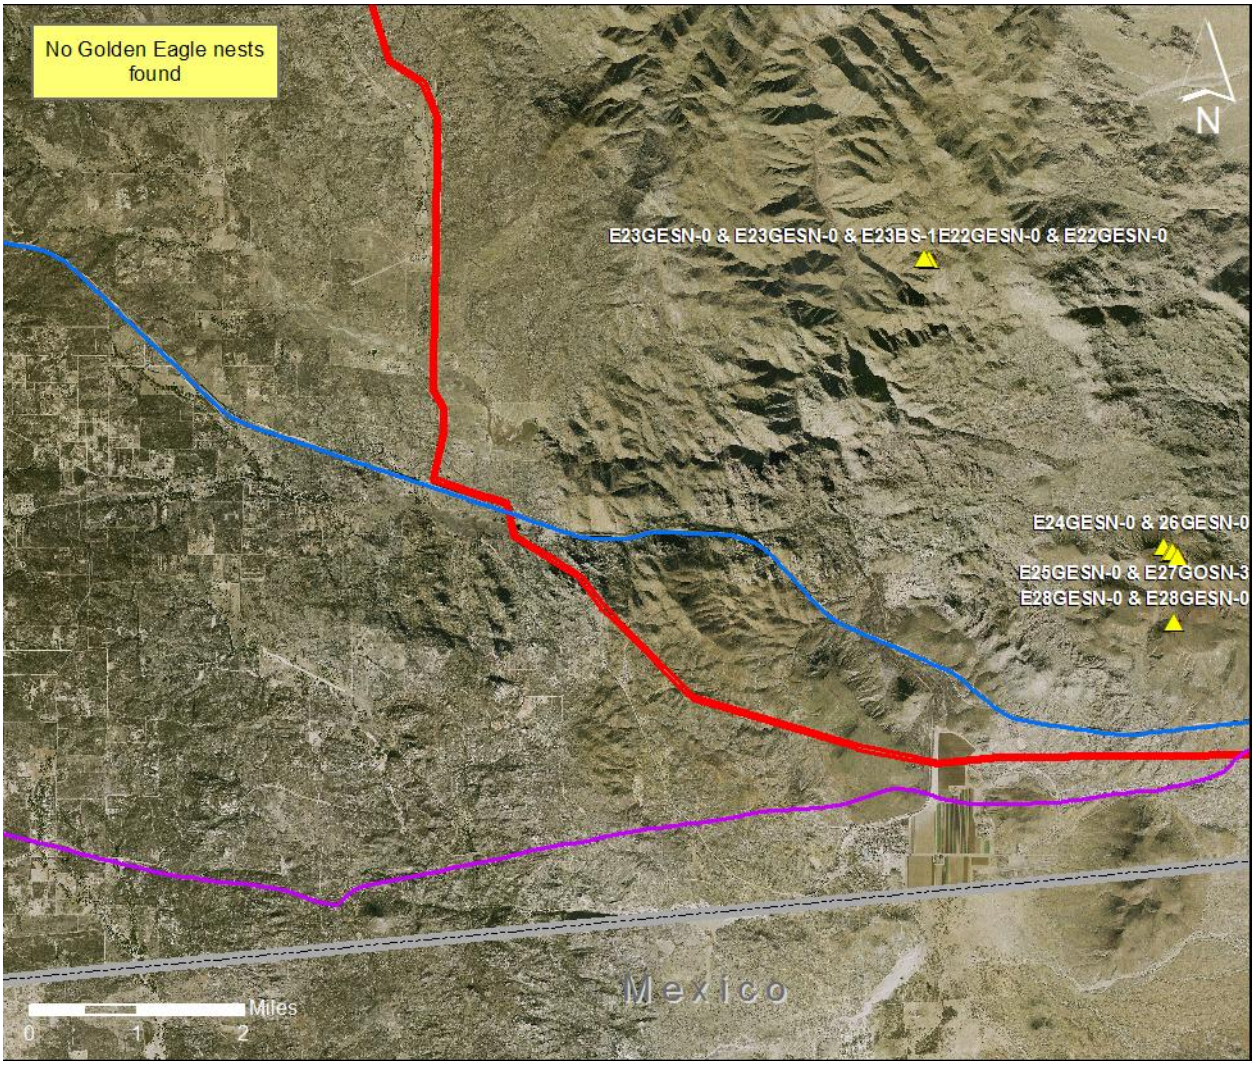

Figure 10. Boundary Peak.

Boundary Peak, inactive territory. All waypoints for species and nests observed, Project alignment, and the helicopter flight paths are provided.

This is an historically documented territory (West 1988); no Golden Eagle nests were observed during this survey.

Canebrake

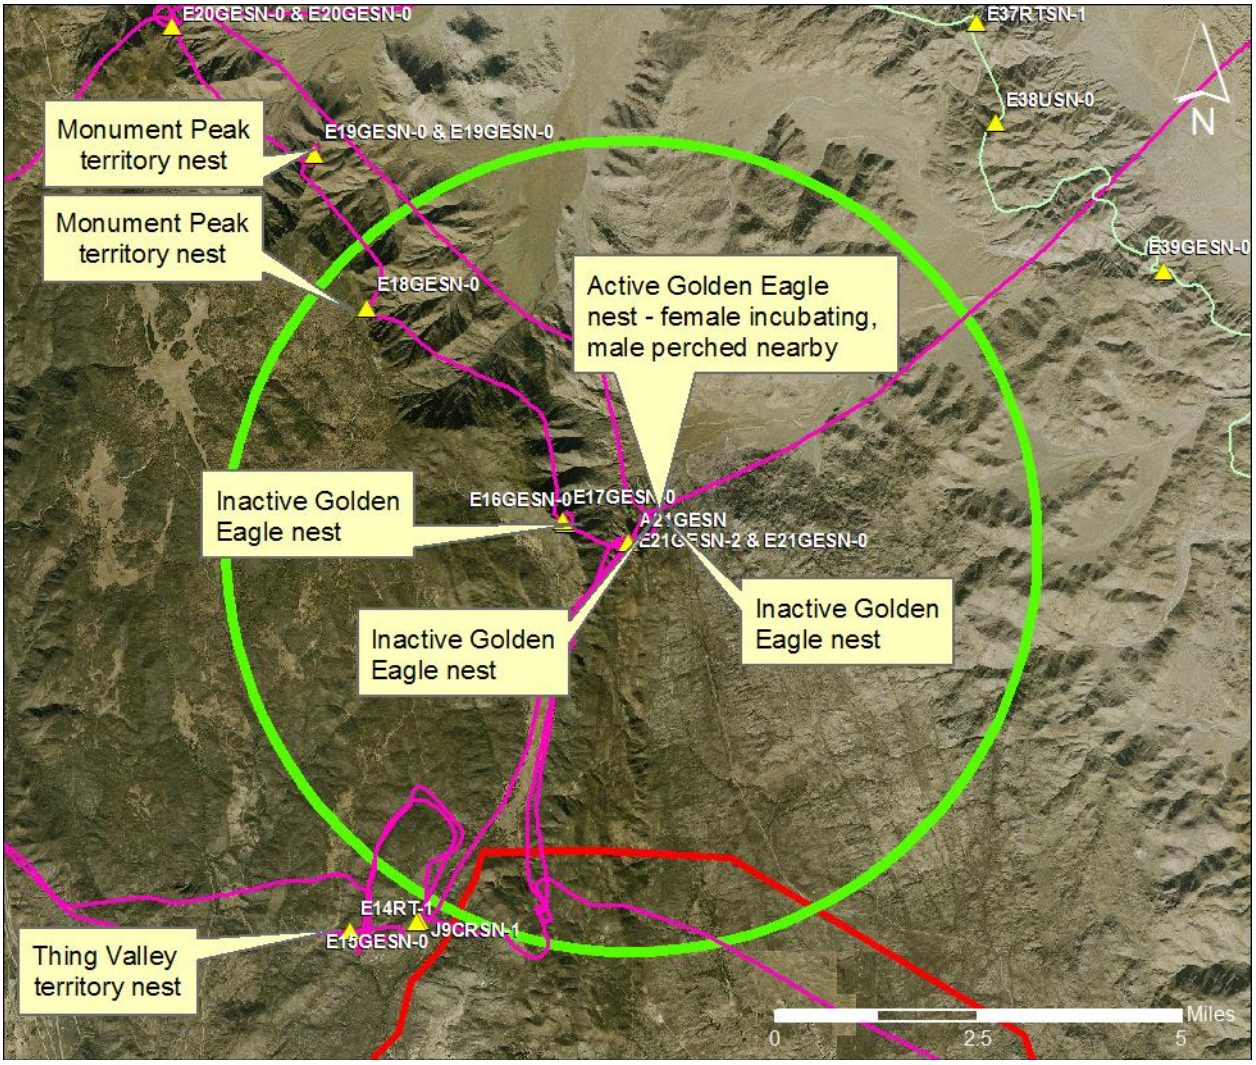

Figure 11. Canebrake.

Canebrake, active and occupied territory. All waypoints for species and nests observed, the helicopter flight path, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

Two Golden Eagles were observed during this survey; the female was incubating and the male was perched nearby.

Canebrake

Active Golden Eagle nest (E21GESN-1); good condition with incubating female.

An inactive Golden Eagle nest (E16GESN-0); good condition.

Carrizo Gorge

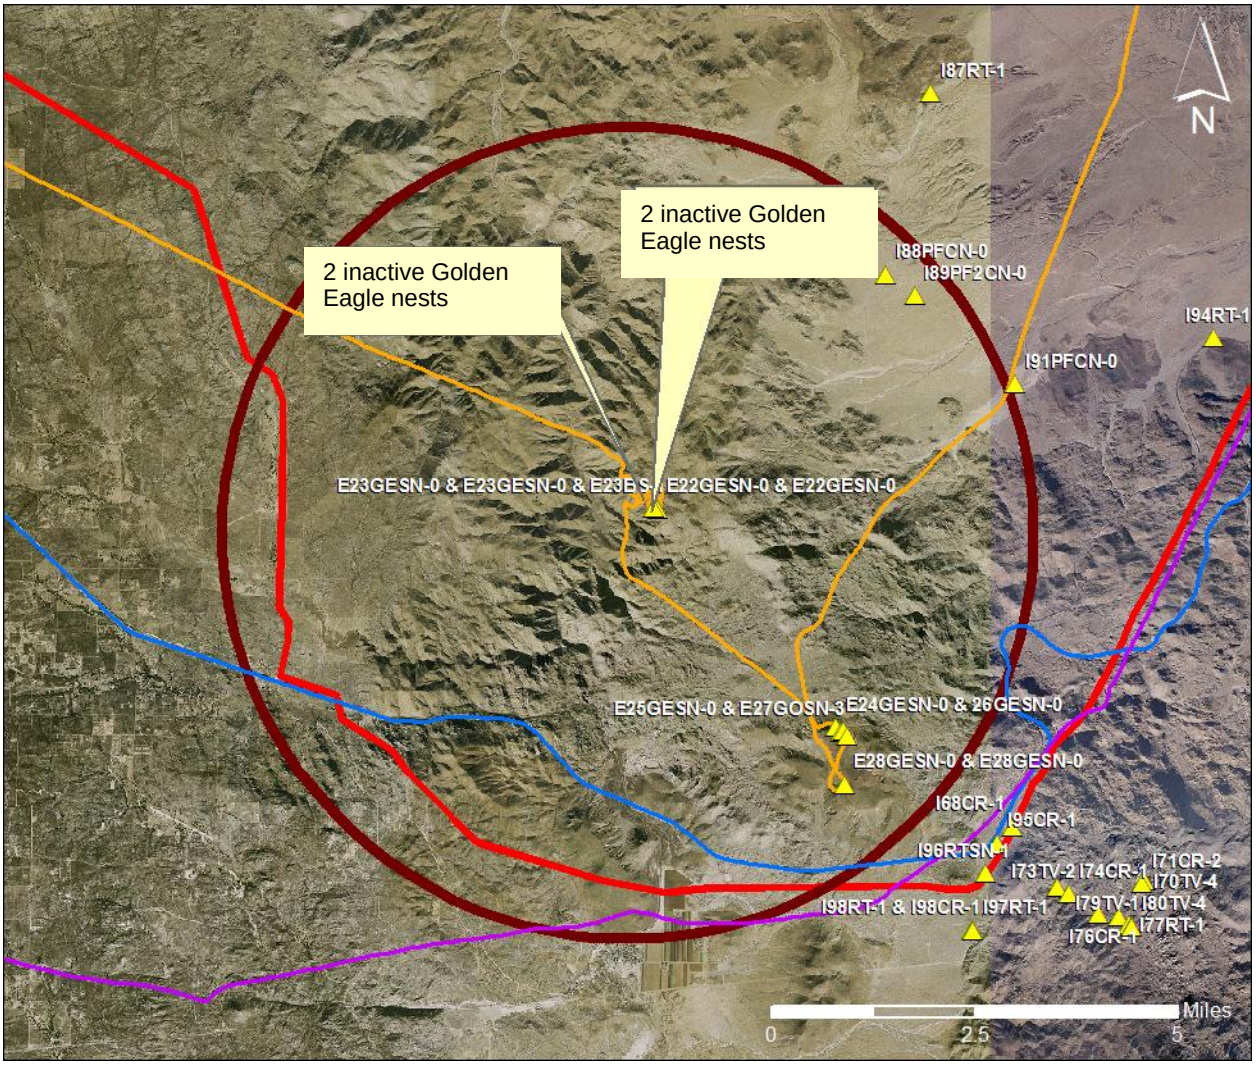

Figure 12. Carrizo Gorge.

Carrizo Gorge, inactive territory. All waypoints for species and nests observed, the helicopter flight paths, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

No active Golden Eagle nests were found.

Carrizo Gorge

Inactive Golden Eagle nest (E23GESN-0); fair condition. One of two nests at this waypoint.

Inactive Golden Eagle nest (E23GESN-0); poor condition, second of two nests at this waypoint.

Coyote Mountains - East

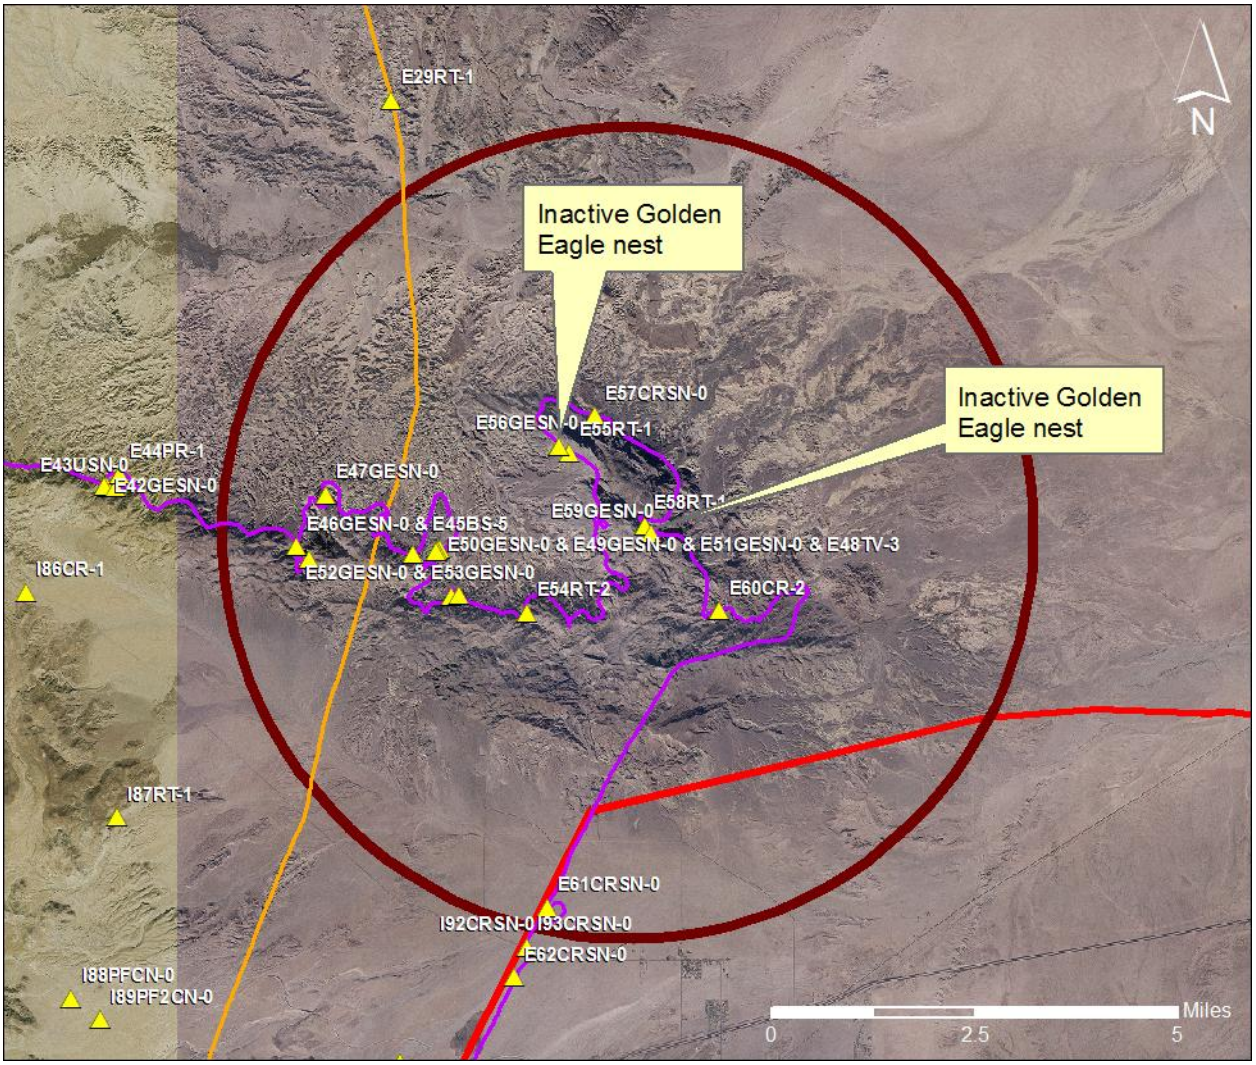

Figure 13. Coyote Mountains - East.

Coyote Mountains - East, inactive territory. All waypoints for species and nests observed, the helicopter flight paths, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

No active Golden Eagle nests observed.

Coyote Mountains - East

Inactive Golden Eagle nest (E59-GESN-0); poor condition, old nest, possibly the early construction of a nest that was eventually abandoned.

Coyote Mountains - West

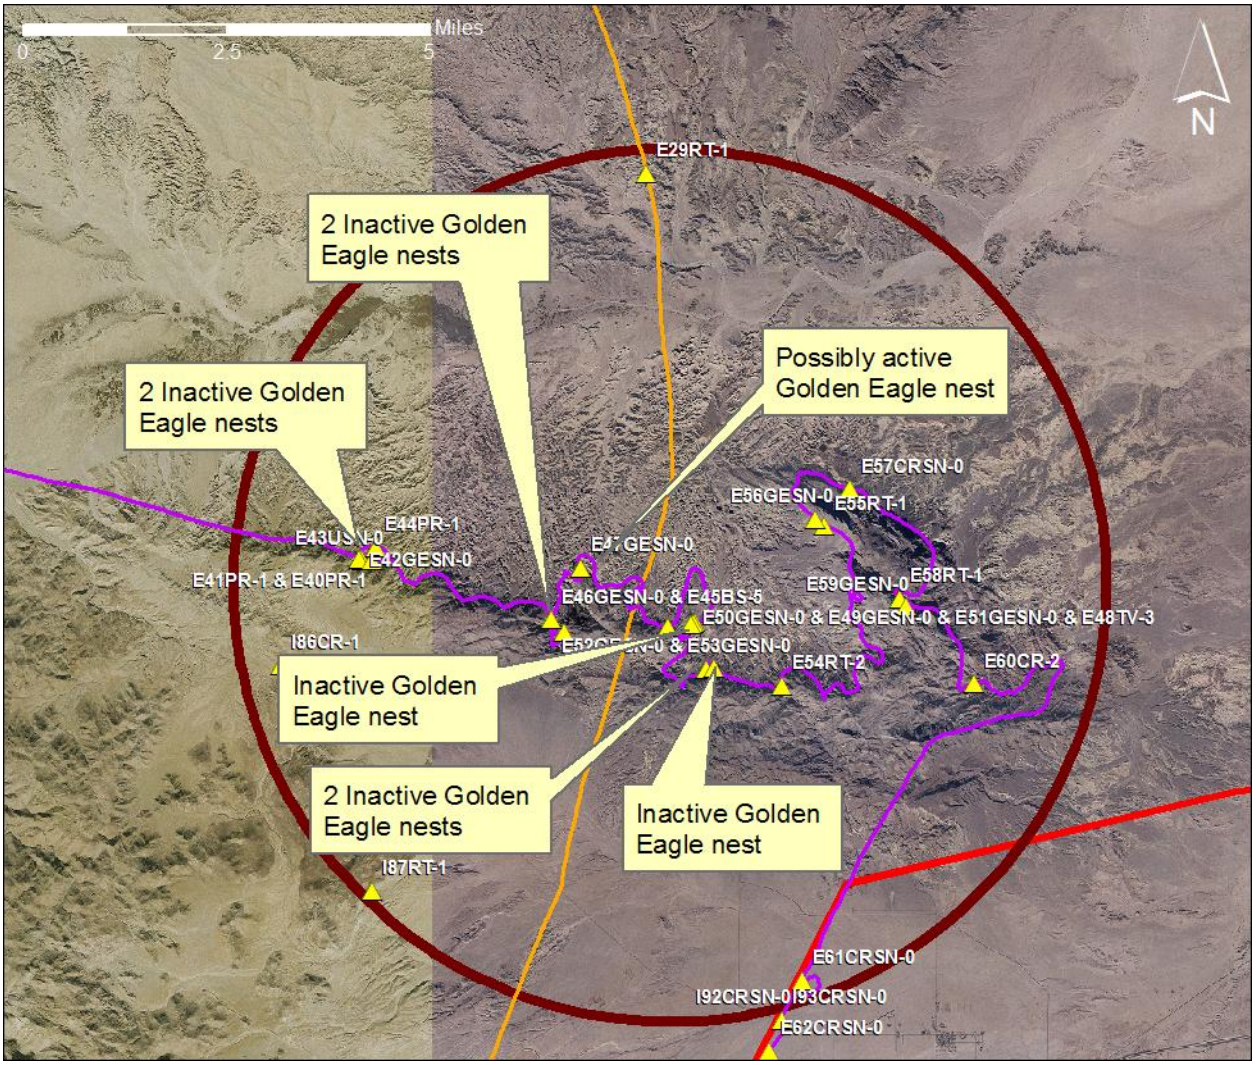

Figure 14. Coyote Mountains - West.

Coyote Mountains - West, inactive territory. All waypoints for species and nests observed, the helicopter flight paths, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

No active Golden Eagle nests observed.

Coyote Mountains - West

Inactive Golden Eagle nest (E42-GESN-0); fair condition, probably used in the last 2 to 3 years based on accumulation of white wash on rock wall. One of two nests at this location.

El Cajon Mountain

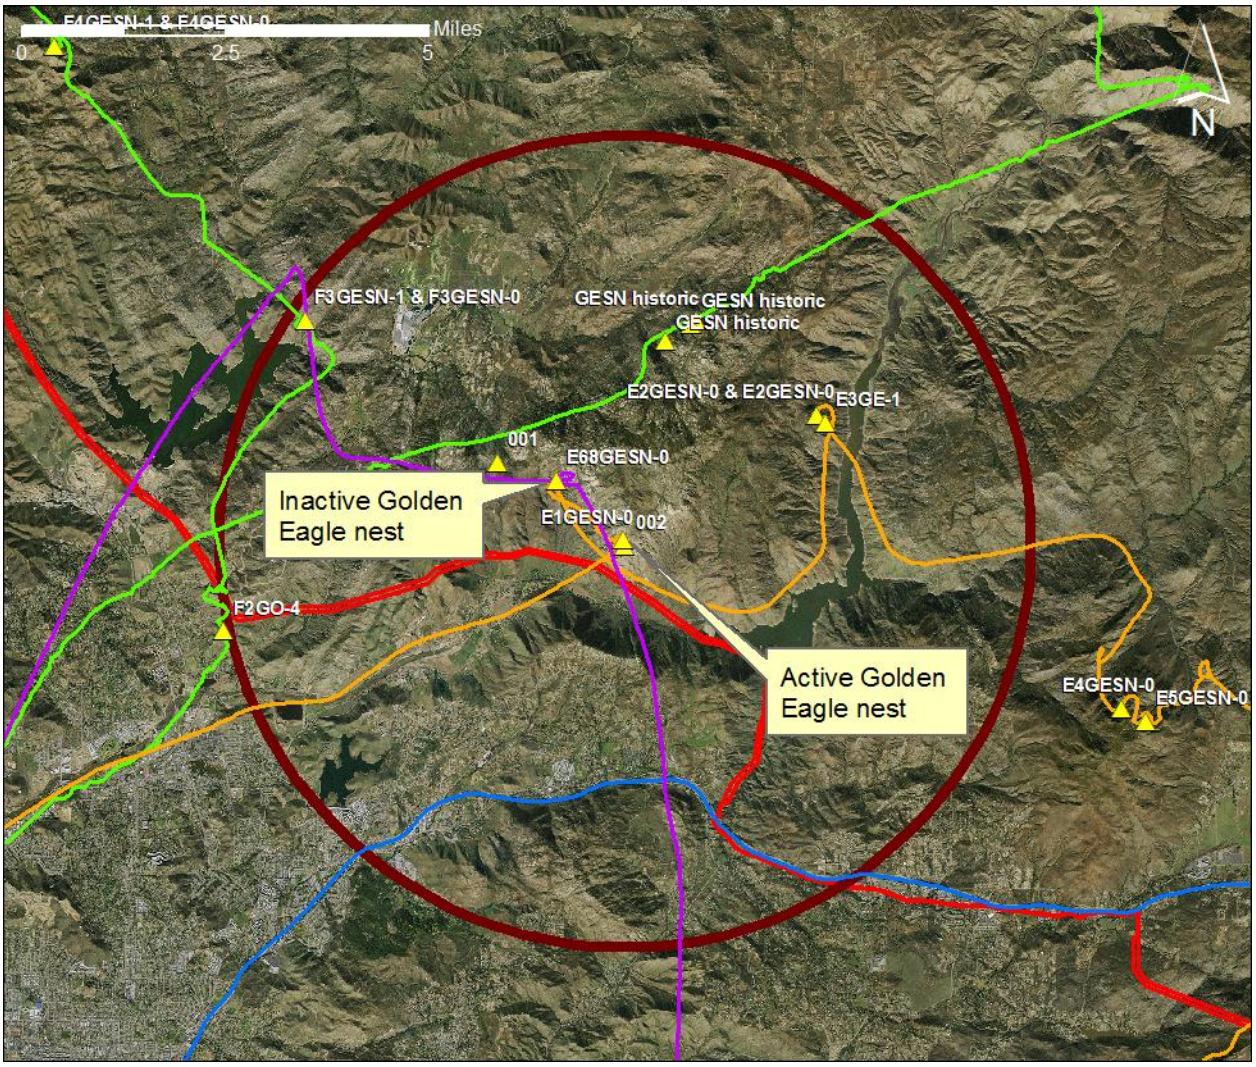

Figure 15. El Cajon Mountain.

El Cajon Mountain, active territory without reproduction. All waypoints for species and nests observed, the helicopter flight paths, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

Two adult Golden Eagles observed during WRI annual ground surveys of the territory during January and February, 2010.

El Cajon Mountain

An active Golden Eagle nest (E1-GESN-0); good condition, with new material recently added in the center of the nest.

Fosters

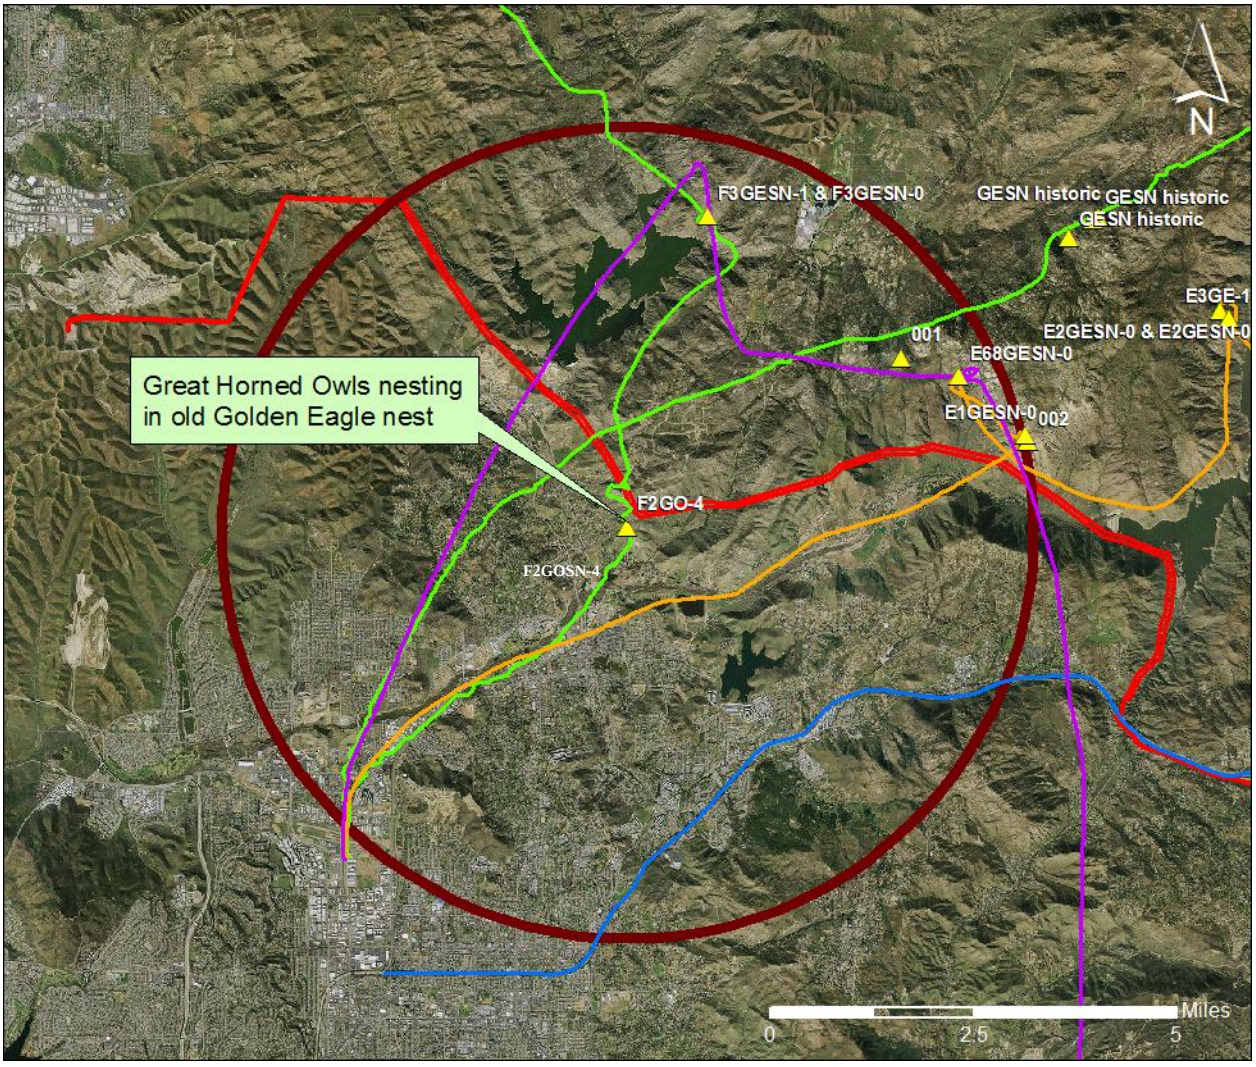

Figure 16. Fosters.

Fosters, inactive territory. All waypoints for species and nests observed, the helicopter flight paths, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

Old Golden Eagle nest currently being used by Great Horned Owls in 2010.

Fosters

Great Horned Owls (female with nestlings) occupying an old Golden Eagle nest (F2GOSN-4).

Hauser Canyon

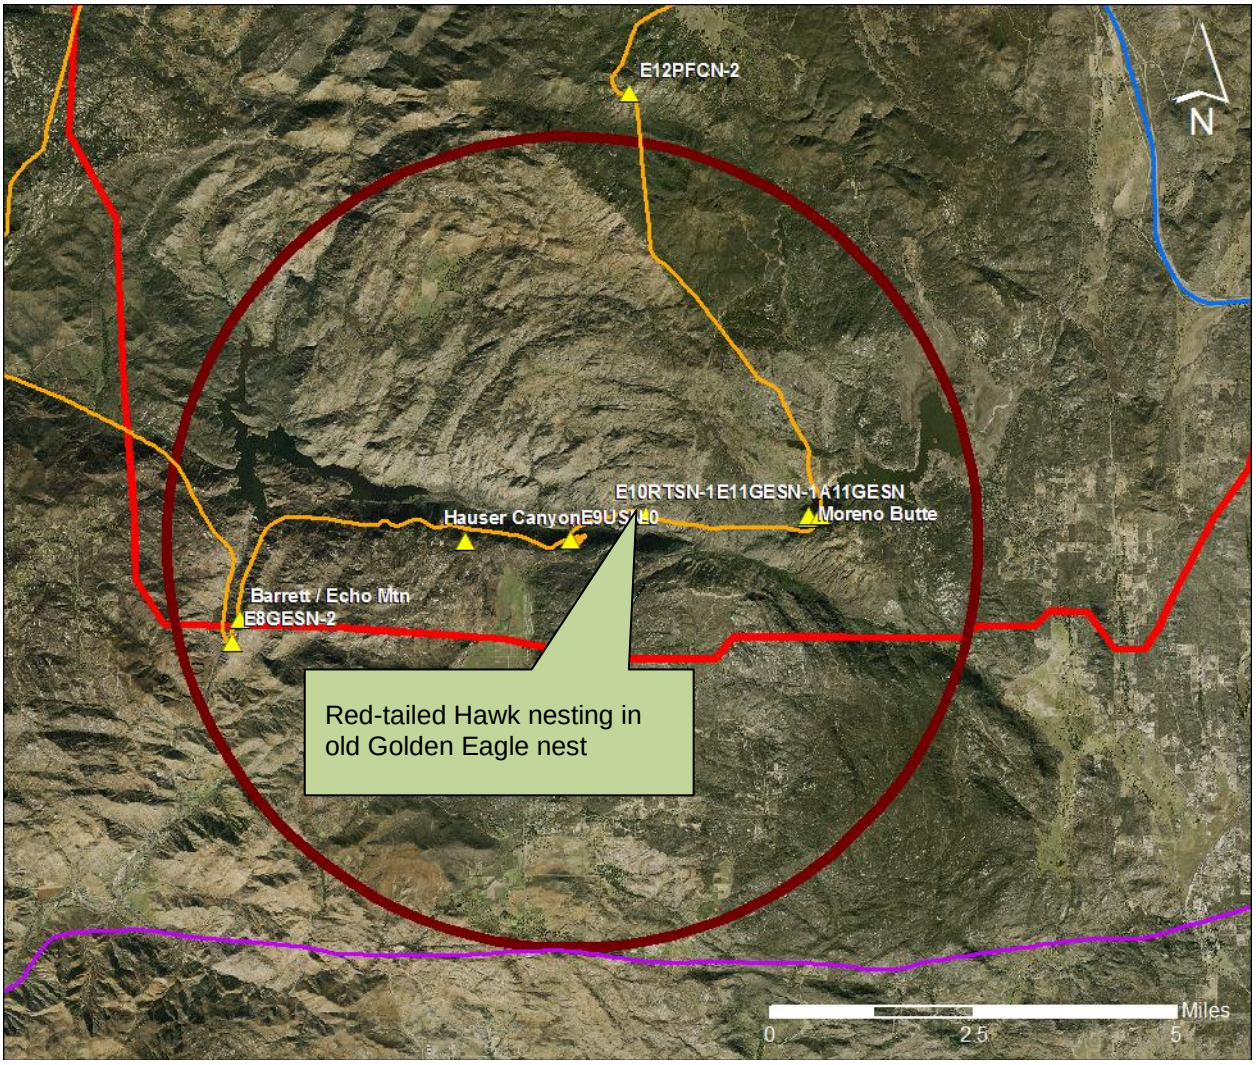

Figure 17. Hauser Canyon.

Hauser Canyon, inactive territory. All waypoints for species and nests observed, the helicopter flight paths, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

Old Golden Eagle nest currently being used by a Red-tailed Hawk.

Iron Mountain

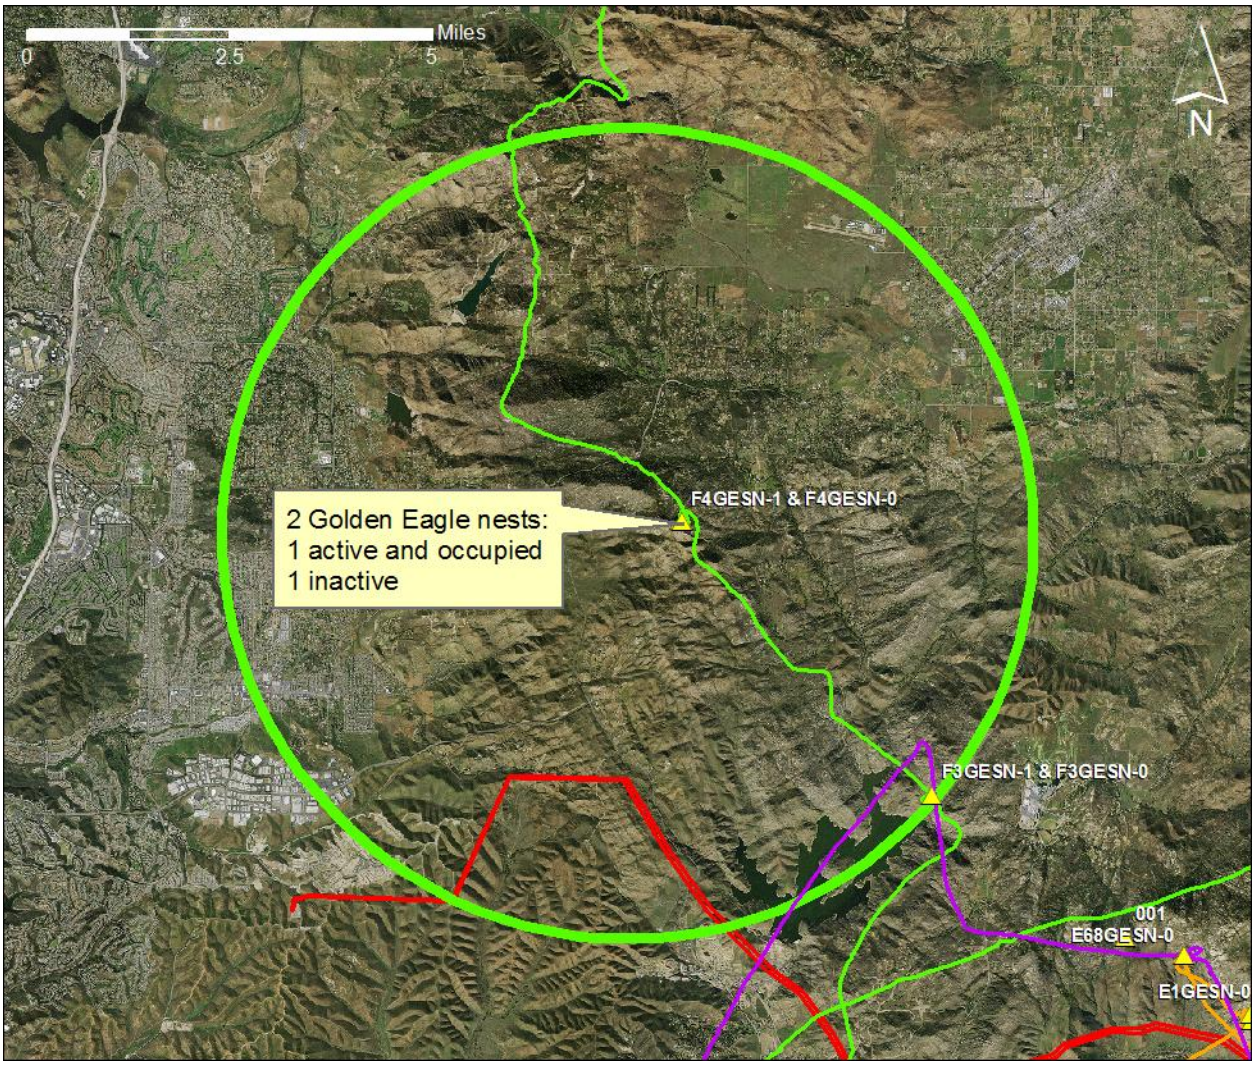

Figure 18. Iron Mountain.

Iron Mountain, active and occupied territory. All waypoints for species and nests observed, the helicopter flight paths, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

Incubating Golden Eagle female observed during WRI annual ground surveys of the territory during January and February, 2010.

Iron Mountain

View of Iron Mountain cliff side (Sole Peak); nest was observed during WRI ground surveys January through February. Two adults were observed building the nest and, later, the incubating female was seen.

Lake Moreno / Moreno Butte

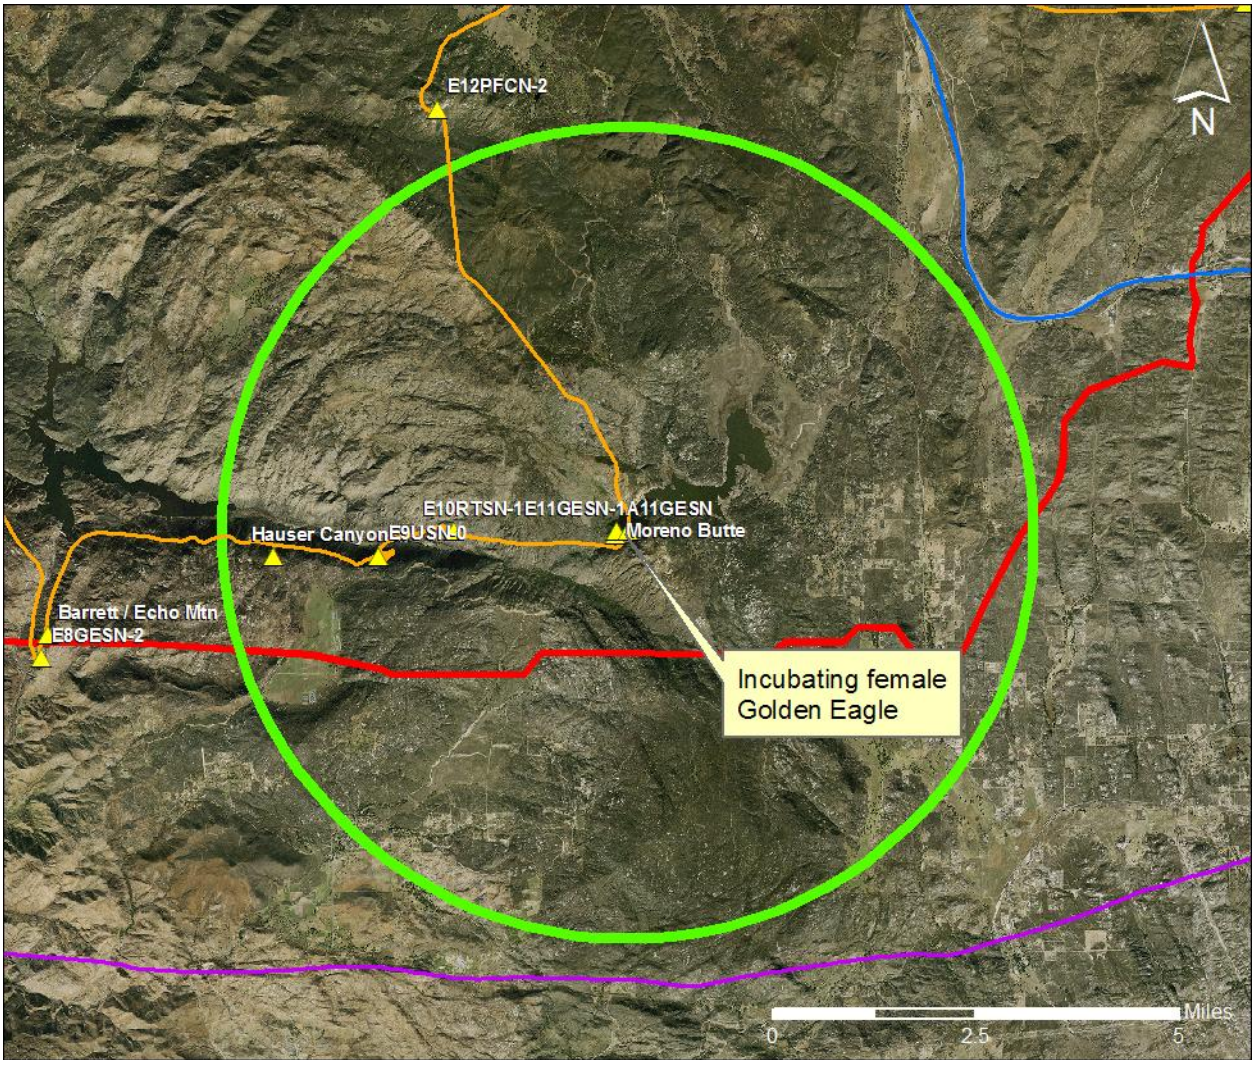

Figure 19. Lake Moreno / Moreno Butte.

Lake Moreno / Moreno Butte, active and occupied territory. All waypoints for species and nests observed, the helicopter flight paths, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

Incubating Golden Eagle female observed during this survey.

Lake Moreno / Moreno Butte

An active Golden Eagle nest (E11GESN-1); good condition with incubating female observed.

Lyons Peak

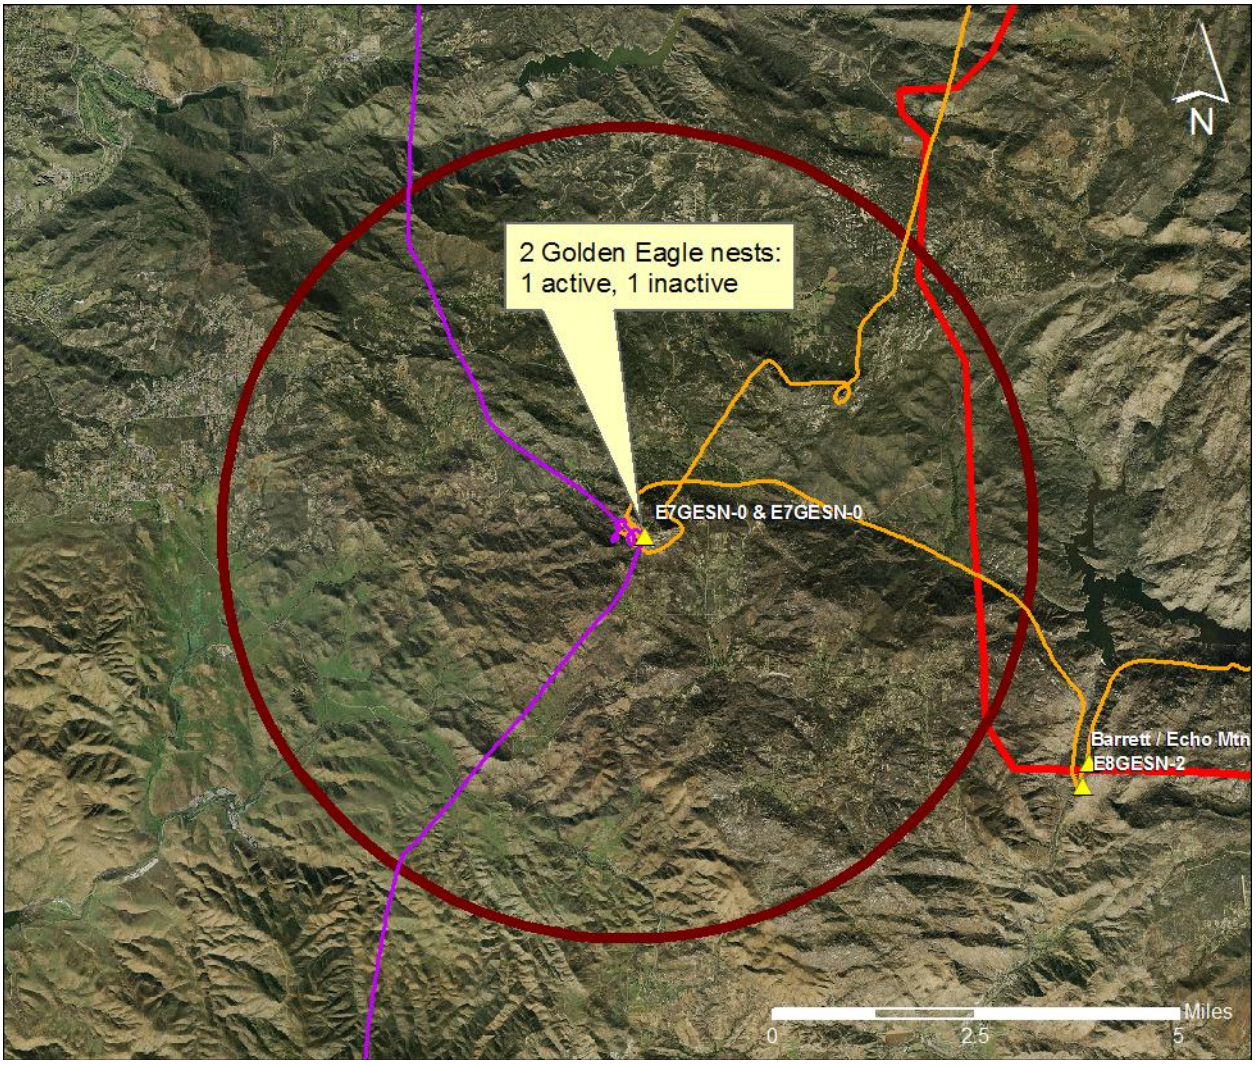

Figure 20. Lyons Peak.

Lyons Peak, active territory without reproduction. All waypoints for species and nests observed, the helicopter flight paths, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

Two adult Golden Eagles observed during WRI's annual ground surveys of the territory during January and February, 2010.

Mountain Springs

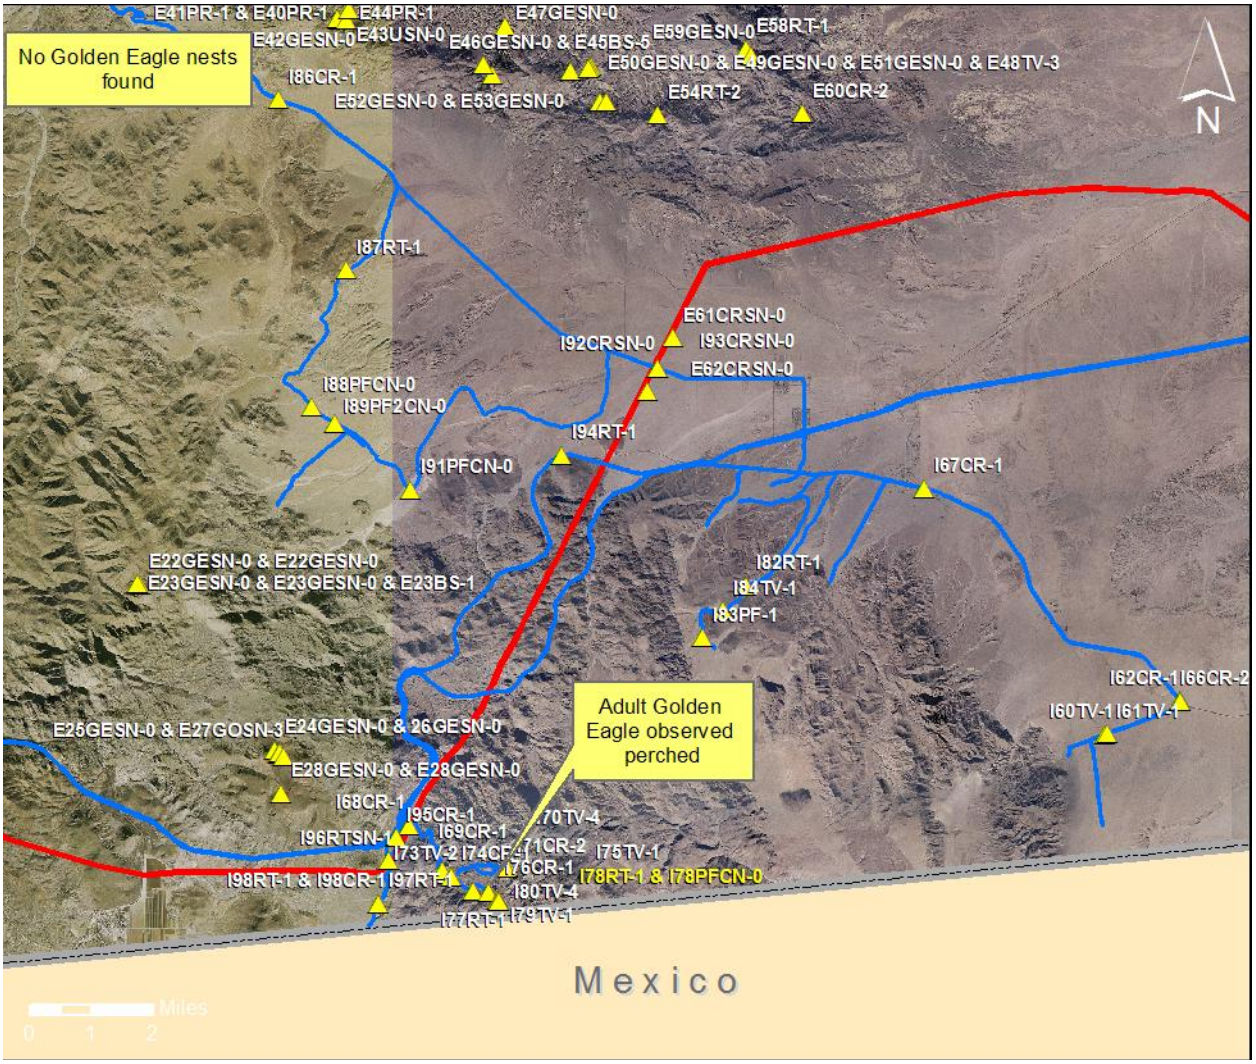

Figure 21. Mountain Springs.

Mountain Springs, inactive territory. All waypoints for species and nests observed, Project alignment, and the ground survey path are provided.

This is an historically documented territory (West 1988); no Golden Eagle nests were observed during this ground survey, however one adult Golden Eagle was seen perched in the In-Ko-Pah Mountains close to the Mexican border.

Rock Mountain

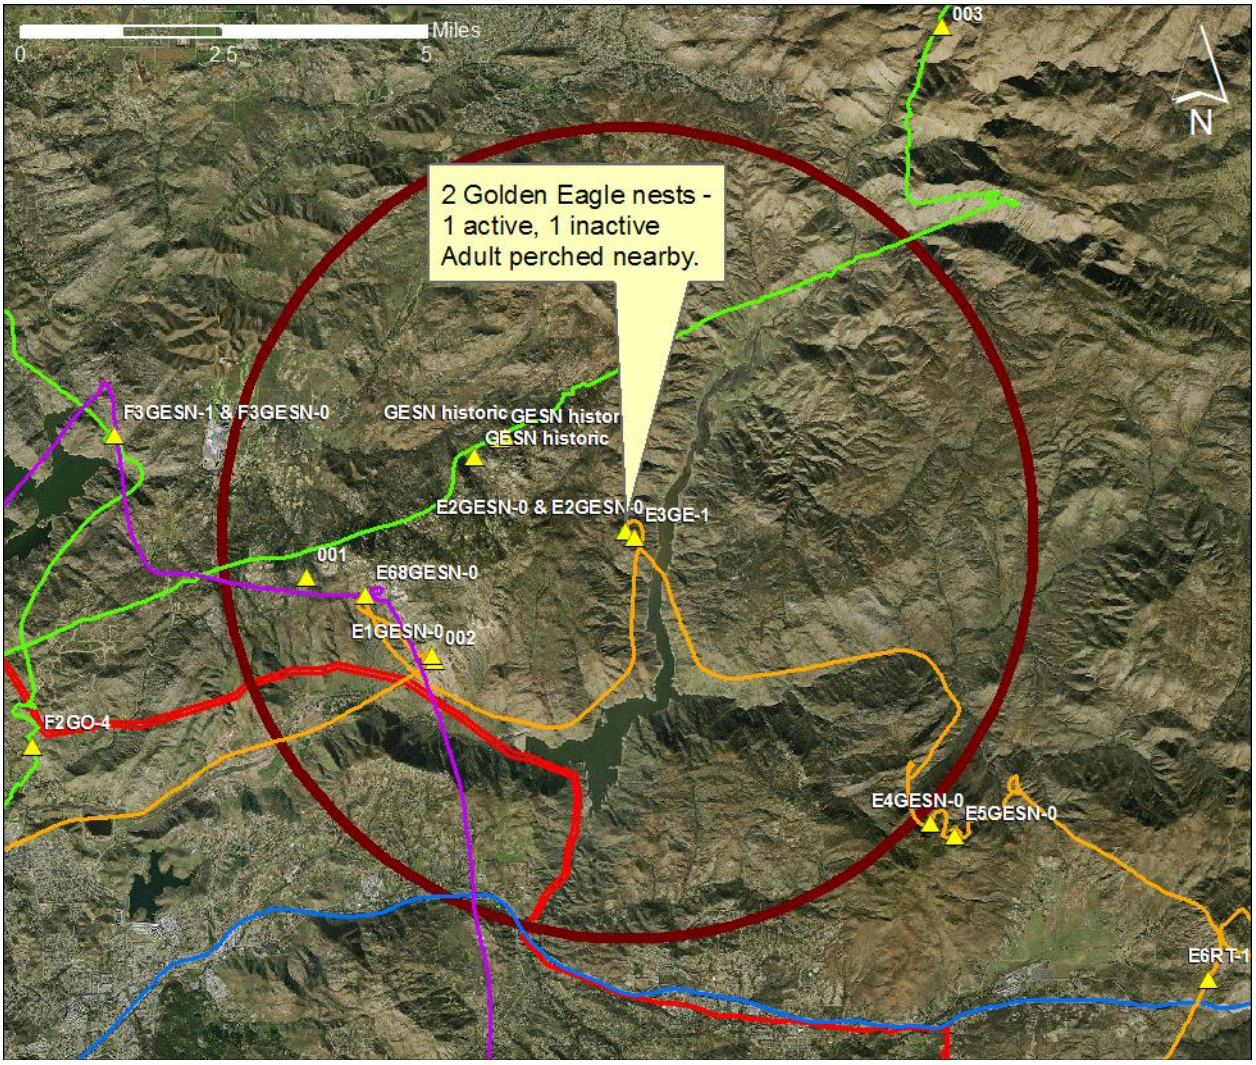

Figure 22. Rock Mountain.

Rock Mountain, active territory. All waypoints for species and nests observed, the helicopter flight paths, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

One adult Golden Eagle was seen perched near the nest site.

Rock Mountain

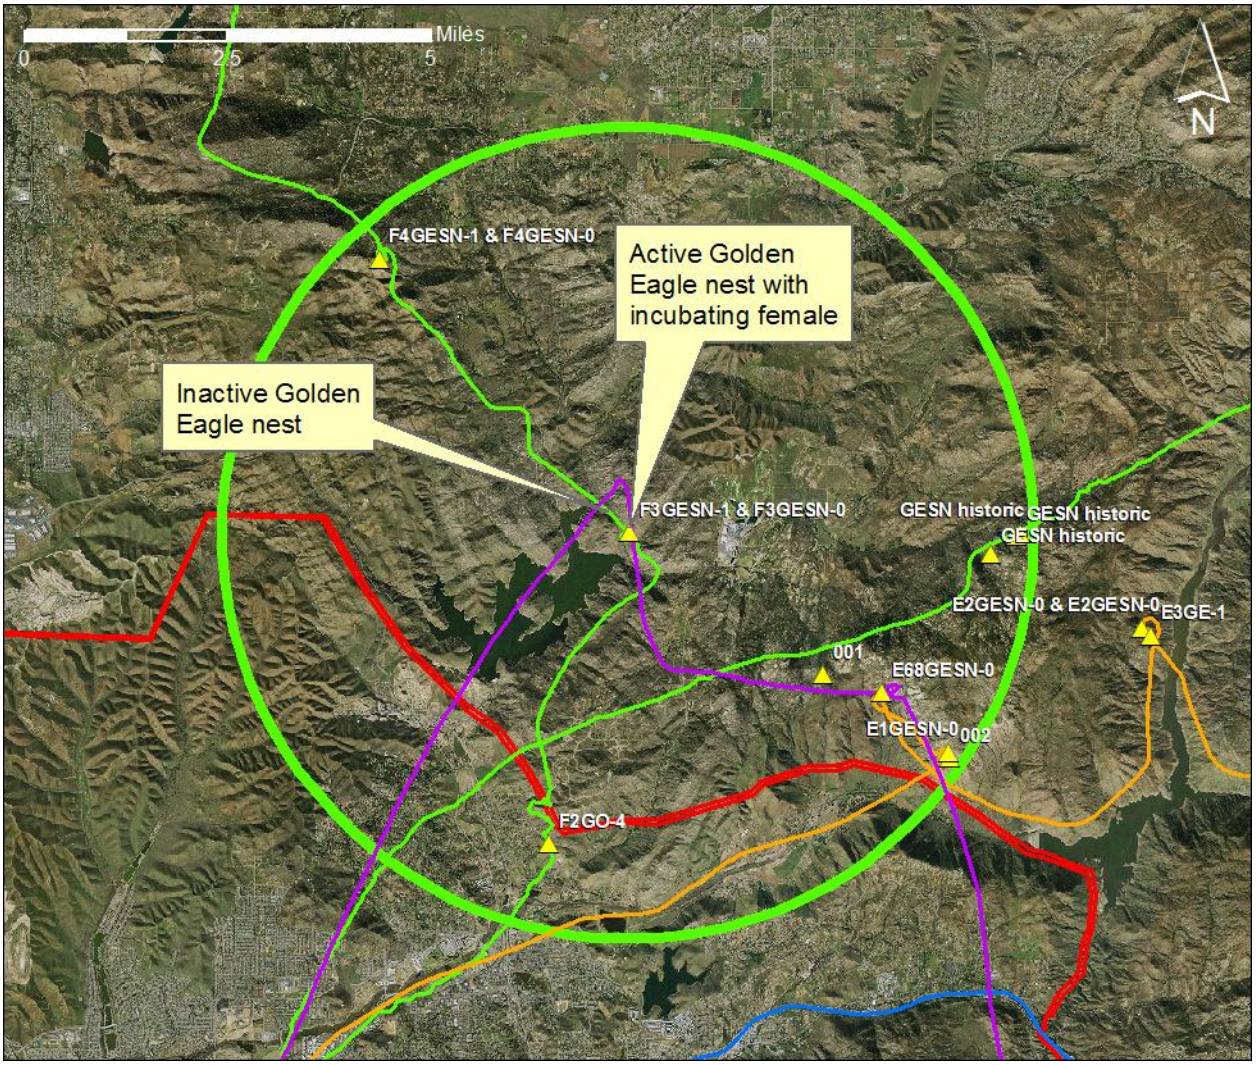
A Golden Eagle (E3GE-1) perched near nest E2GESN-0, shown in the following photo.

An active Golden Eagle nest (E2GESN-0); good condition with new material added recently. One of two nests found at this location.

Rock Mountain

An inactive Golden Eagle nest (E2GESN-0); poor condition. The second of two nests found at this location.

San Vicente



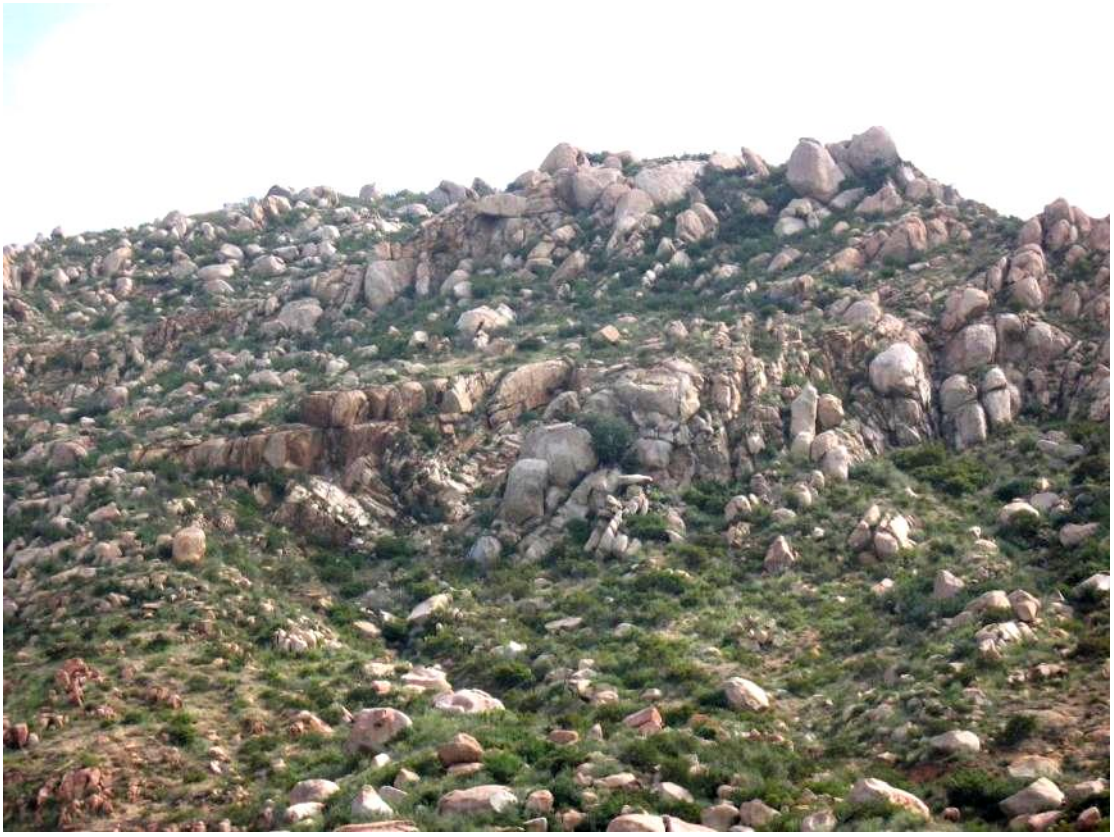


Figure 23. San Vicente.

San Vicente, active and occupied territory (incubating female observed). All waypoints for species and nests observed, the helicopter flight paths, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

Incubating Golden Eagle female observed during WRI annual ground surveys of the territory during January and February, 2010.

San Vicente

View of San Vicente cliff containing active nest observed during 2010 surveys.

Table Mountain

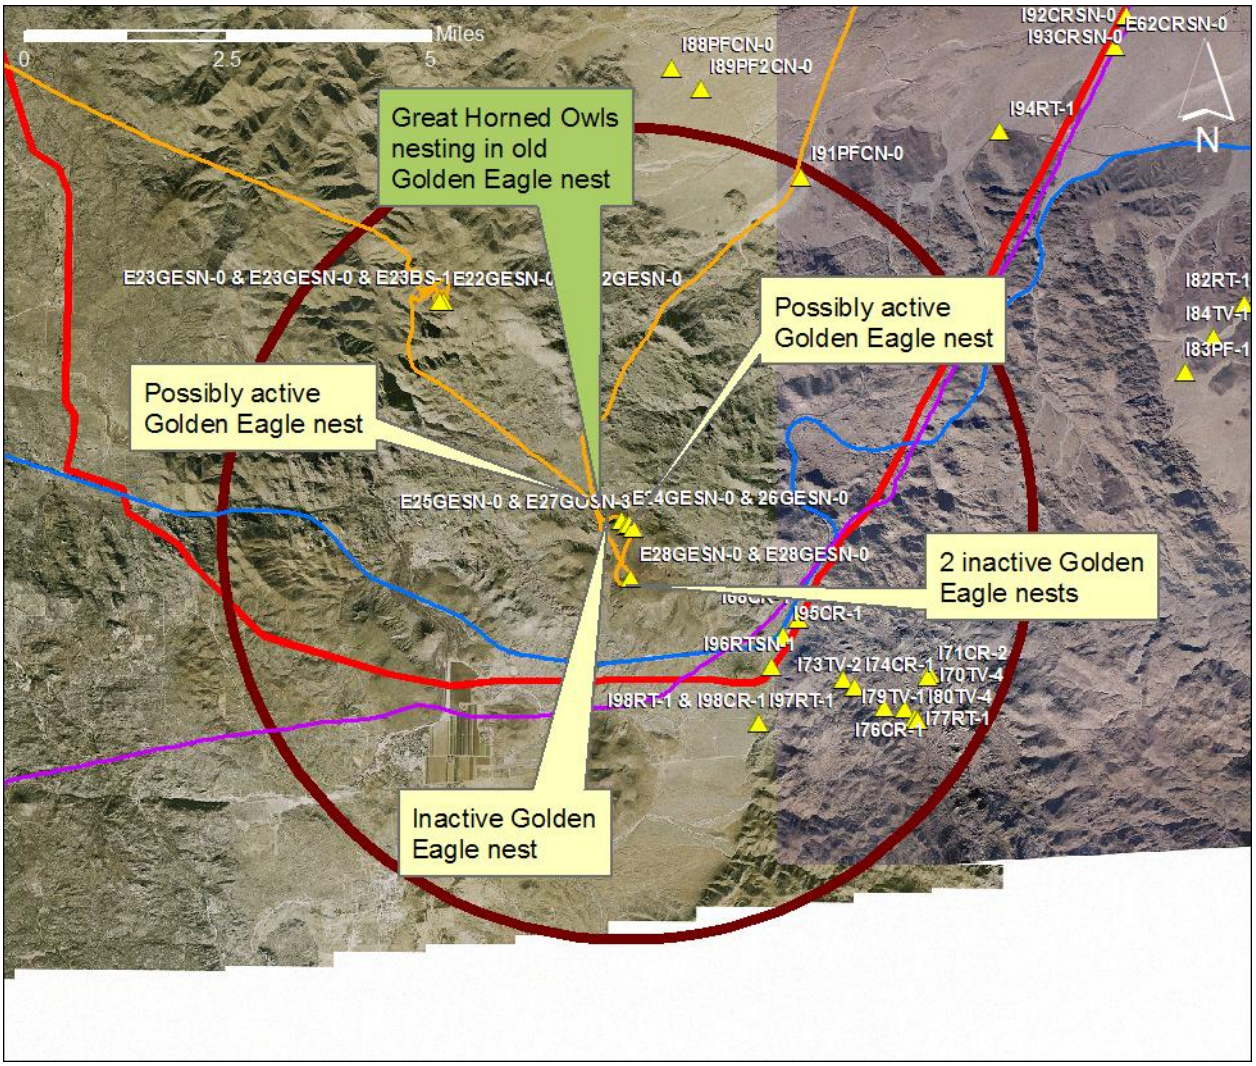

Figure 24. Table Mountain.

Table Mountain, possibly active territory. All waypoints for species and nests observed, the helicopter flight paths, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

Great Horned Owl occupying one of the Golden Eagle nests in this territory during the 2010 breeding season.

Table Mountain

An old Golden Eagle nest (E27GOSN-2) occupied by Great Horned Owls; white downy nestlings can be seen in the middle of the nest.

Thing Valley

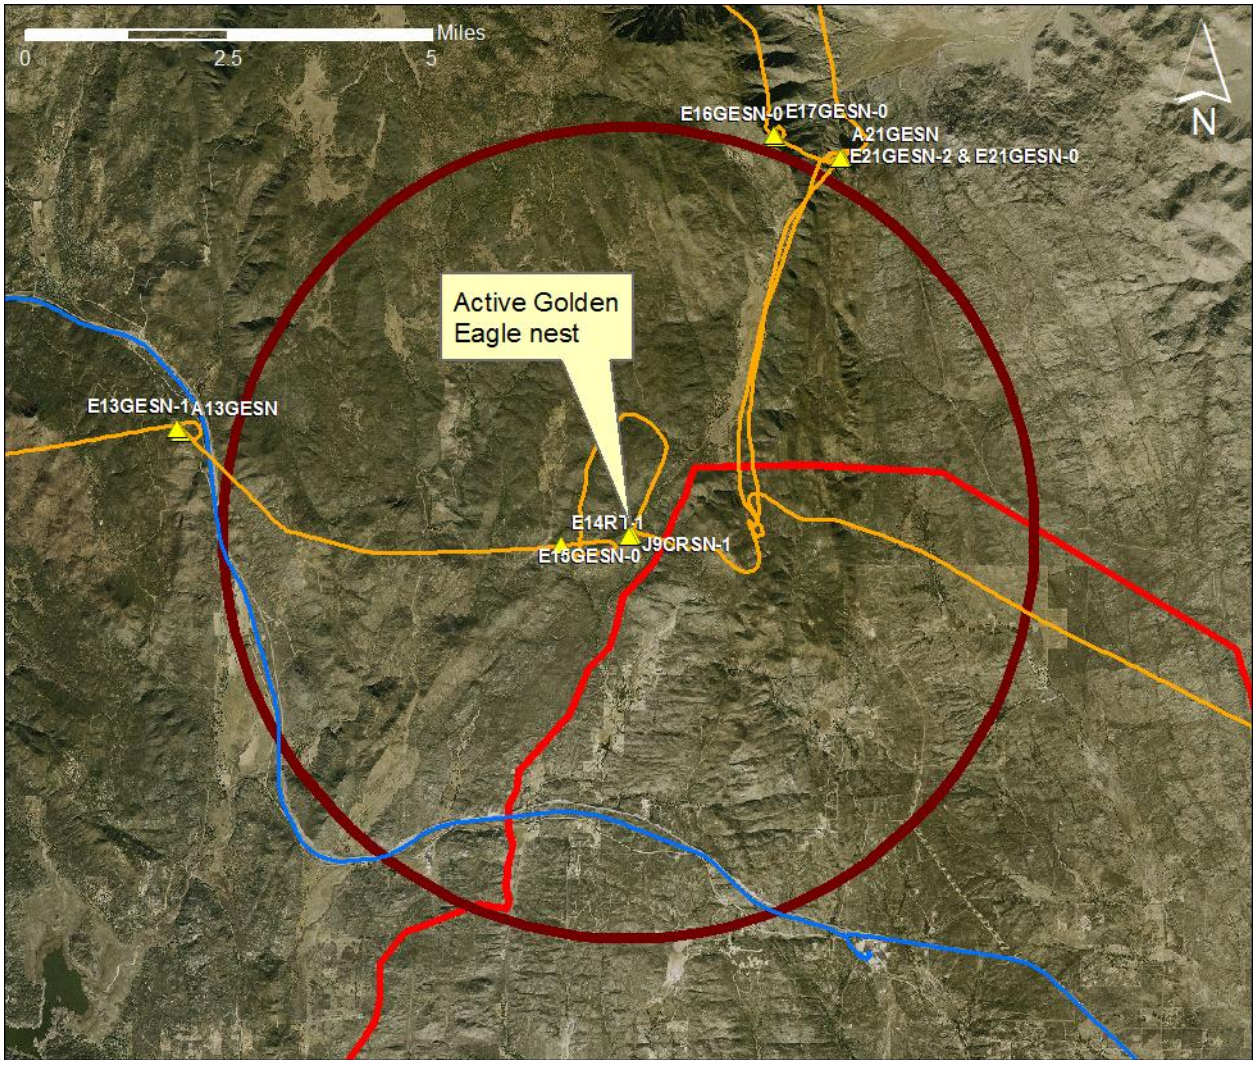

Figure 25. Thing Valley.

Thing Valley, active territory without reproduction. All waypoints for species and nests observed, the helicopter flight paths, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

Active Golden Eagle nest observed but without an incubating adult (unoccupied).

Viejas Mountain

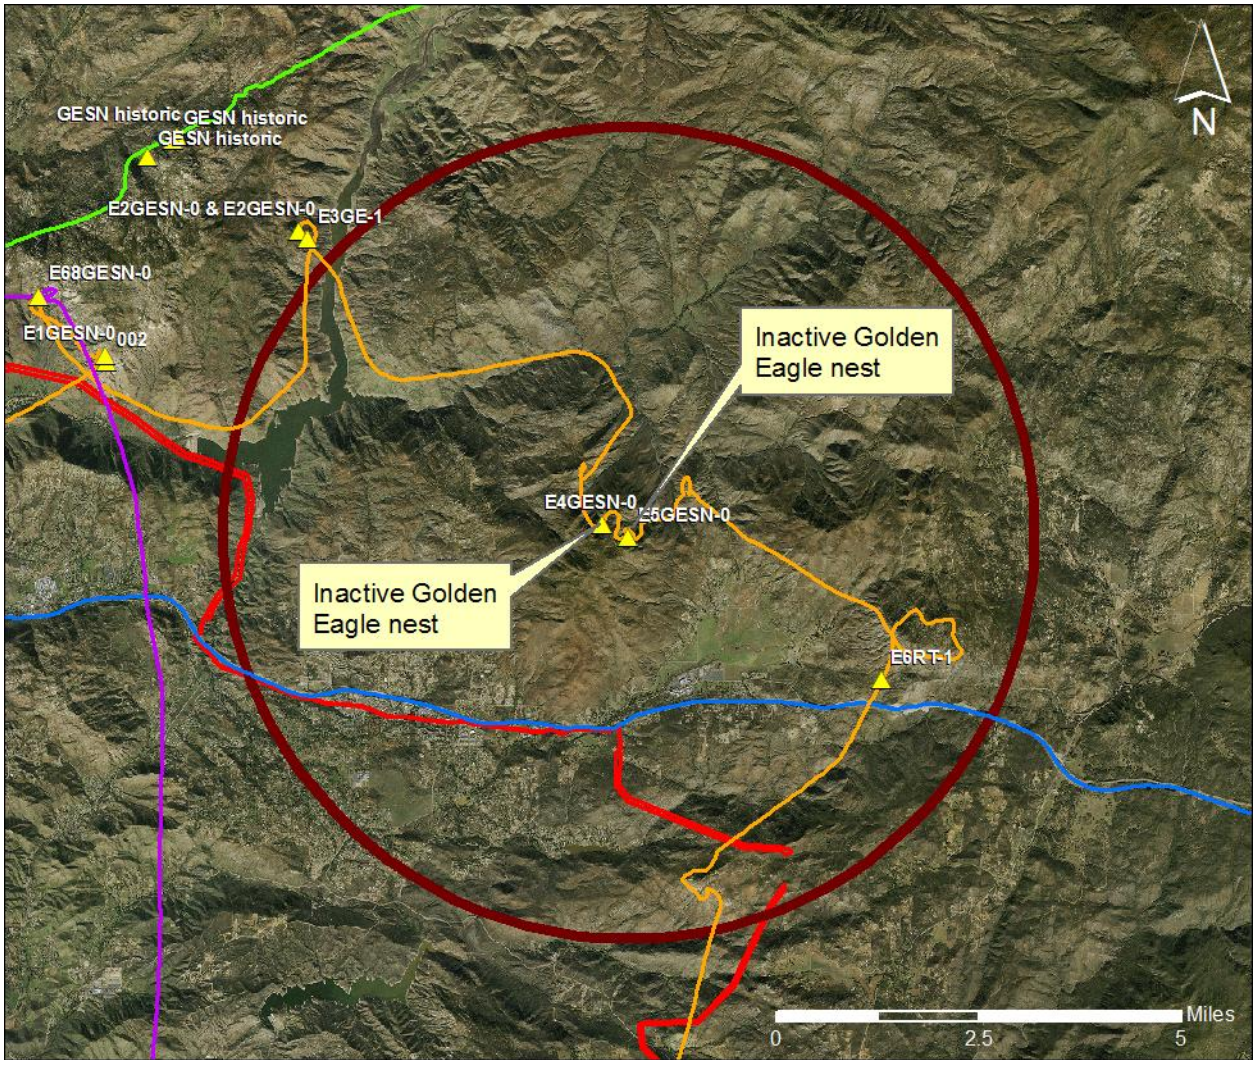

Figure 26. Viejas Mountain.

Viejas Mountain, inactive territory. All waypoints for species and nests observed, the helicopter flight paths, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

No active Golden Eagle nests observed.

Viejas Mountain

An inactive Golden Eagle nest (E4GESN-0); poor condition, an old nest.

An inactive Golden Eagle nest (E5GESN-0); poor condition.

DISCUSSION OF FINDINGS

While evaluating the data from this 2010 Phase 1 survey, it is important to take the recent drought and its effects on Golden Eagle reproduction into account. The California Department of Water Resources advises that the state is entering its fourth year of serious drought as a result of below average precipitation and run-off since the fall of 2006 (State of California 2010). Without the context of knowing the effects of the drought on Golden Eagle breeding, one might come to a false conclusion about the population of Golden Eagles in the study area. Because breeding in Southern California starts in January and this study was initiated in late March when only those eagles that were successful would be incubating, no opportunity was afforded to actually get a true number of pairs of Golden Eagles that attempted to reproduce but failed. Therefore, the number of active territorial pairs of Golden Eagles in the study area could be higher than those actually identified.

Because prohibition against take and the new regulations apply not only to nest sites but also includes foraging areas, a circle with an approximate 5-mile radius (approximately 78 square miles) has been placed around the Golden Eagle core nesting areas on the survey maps to reflect estimated foraging habitat. Although we have applied the approximate 5-mile radius as "suitable foraging area" in "favorable habitat", most desert-nesting Golden Eagles actually have much larger territories. Research on Golden Eagles in prime habitat indicates territories are 20 to 25 square miles in size (McGrady et al. 2002; Bittner unpublished data) but most desert-nesting Golden Eagles have much larger territories encompassing 100 to 120 square miles due to the lack of prime foraging areas (Bittner unpublished data).

During Phase 1 surveys, we observed 42 Golden Eagle nests. These nests accounted for 19 Golden Eagle territories; 9 active, 2 possibly active, and 8 inactive. Five of the active Golden Eagle territories (Barrett/Echo Mountain, Canebrake, Iron Mountain, Lake Moreno/ Moreno Butte, and San Vicente) were found with incubating females. Every territory in the study area, except for Bell Bluff, Boundary Peak, and Mountain Springs, had nest evidence of Golden Eagle breeding attempts in recent years but not all had evidence of 2010 activity. As previously noted, this is not unusual because healthy populations of Golden Eagles may average as few as 62% of pairs breeding in any one year (Kochert et al. 2002).

Numerous raptors and mammals were also observed (i.e., Antelope Ground Squirrels, American Kestrel, Bighorn Sheep, Common Ravens, Great Horned Owls, Jackrabbits, Prairie Falcons, Red-tailed Hawks, and Turkey Vultures) totaling 95 wildlife documentations, including 24 Golden Eagles and 6 Desert Bighorn Sheep.

PHASE 2 REPORT

ABSTRACT – PHASE 2 SURVEYS

This section reports on findings of the **Phase 2** surveys conducted in San Diego County, California, to record and report productivity for Golden Eagles within 4 miles of the Sunrise Powerlink project boundary in order to comply with the U.S. Fish and Wildlife Service recommendations. The 9 active Golden Eagle territories identified during Phase 1 surveys were revisited by WRI biologists via helicopter. These active territories were also surveyed throughout late April 2010 and early May 2010 by WRI during annual research and monitoring as well as during ground and aerial surveys being conducted for other projects around the area. The 5 occupied territories (Barrett/Echo Mountain, Canebrake, Iron Mountain, Lake Moreno/Moreno Butte, and San Vicente) identified during Phase 1 surveys were confirmed active and productive during Phase 2 surveys by the observation of nestlings in each of the territories. Golden Eagle nestlings in the Barrett/Echo Mountain, Iron Mountain, Lake Moreno/Moreno Butte, and San Vicente territories were banded during WRI's monitoring and research studies. The 2 nestlings at Lake Moreno/Moreno Butte were each fitted with a satellite transmitter. All sightings have been documented with GPS locations and recorded on the attached maps and tables.

METHODS AND CONSTRAINTS

Methods

The study area encompasses part of Southeast San Diego County, an area that has been part of the WRI's 22 year-long Golden Eagle study initiated in 1988. All territories have a known history to WRI and we utilized that data to improve the accuracy of this study.

Only territories identified as active during Phase 1 surveys were surveyed again during Phase 2.

It should be noted that all surveying and reporting complies with the current U.S. Fish and Wildlife Service Interim Golden Eagle Technical Guidance: Inventory and Monitoring Protocols; and Other Recommendations in Support of Golden Eagle Management and Permit Issuance released in 2010 (Pagel et al. 2010).

Survey

We used Hughes-500 helicopters that provided seating for three investigators including 2 Golden Eagle biologists, a Bighorn Sheep biologist, and the pilot.

This final Golden Eagle surveys were conducted by ground and helicopter on May 1,2,9, 14, and 16, 2010 (Figure 27) and incurred approximately 82 person-hours of actual aerial observations. This survey focused only on revisiting active or possibly active territories that were identified during the previous, Phase 1, survey in an effort to confirm reproductive activity. Inactive territories noted during Phase 1 were not surveyed during Phase 2.

It should also be noted that, in addition to scheduled Phase 2 surveys, WRI periodically monitored active nest sites around the Sunrise Powerlink project area during our own ongoing research of Golden Eagle territories in San Diego County, California. As part of this research, WRI banded and placed satellite transmitters on the 2 Lake Moreno/Moreno Butte eaglets (data available upon request).

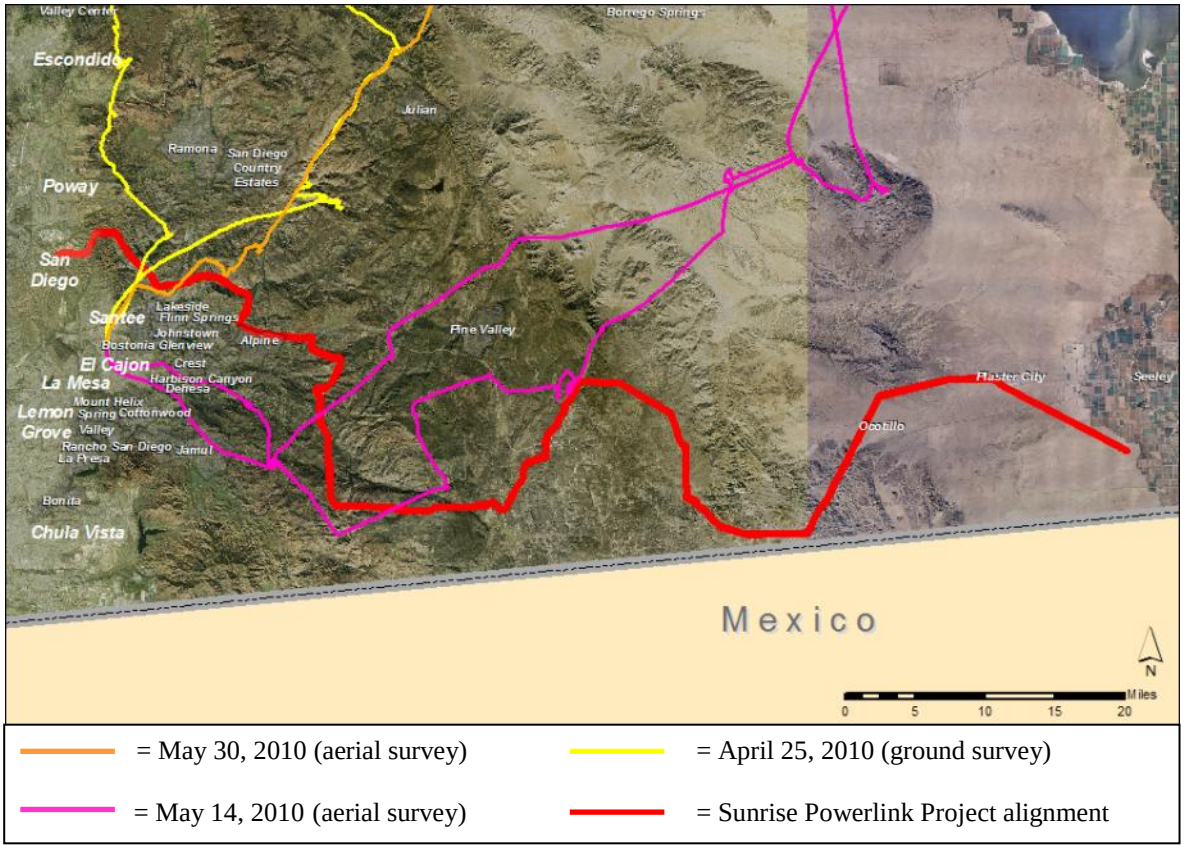

Figure 27. Phase 2 Study Area with Flight Paths and Sunrise Powerlink Project Alignment.

GPS

Nest site and other location-specific data were determined and documented during Phase 2 surveys using hand-held GPS units (Garmin Map60GSx). A sequential number was assigned to each observation that corresponded to the GPS waypoint. Waypoints were recorded using the UTM grid in the WGS 84 Datum. GPS was also used to track our survey routes (Figure 27). Handwritten notes were also taken that documented species and corresponded to each GPS waypoint.

Data

We photographed all active Golden Eagle nests, some other raptor nests, representations of numerous inactive Golden Eagle nest sites, and significant other wildlife species observed. The following data were also specifically collected and are on file at WRI but may not be included in all reports (Appendix A):

- Species
- Number of nests/alternative nests observed
- Condition of each nest and whether or not it was active
- Nest aspect
- Nest elevation

- Nest GPS coordinates
- Nest substrate (cliff, transmission tower, etc.)
- Age class of Golden Eagles and other species if determinable
- Behavior of species observed.

It should be noted that Red-tailed Hawks in particular, as well as other raptors such as Prairie Falcons, sometimes utilize Golden Eagle nests for their own nesting, something observed during some of the Phase 1 surveys for this project.

Constraints

In that this was a diurnal survey focused on Golden Eagles, we were less likely to observe nocturnal and crepuscular raptors (i.e., owls). Aerial surveys also tend to under-represent the smaller species, like the American kestrel and burrowing owl.

The release of the Interim Golden Eagle Technical Guidance in February 2010 and subsequent contracts being finalized in March 2010 resulted in survey flights being scheduled late in the Golden Eagle breeding season. Initiating surveys this late in the season may have resulted in missed observations of adult eagles on territory earlier in the year (December 2009 - February 2010) that did not attempt to produce young.

RESULTS

Golden Eagles

We surveyed a total of 9 active Golden Eagle nests during this phase of the project that represented 9 Golden Eagle territories, 5 of which were occupied and had successfully produced young (Figure 5). These nests were all in good condition.

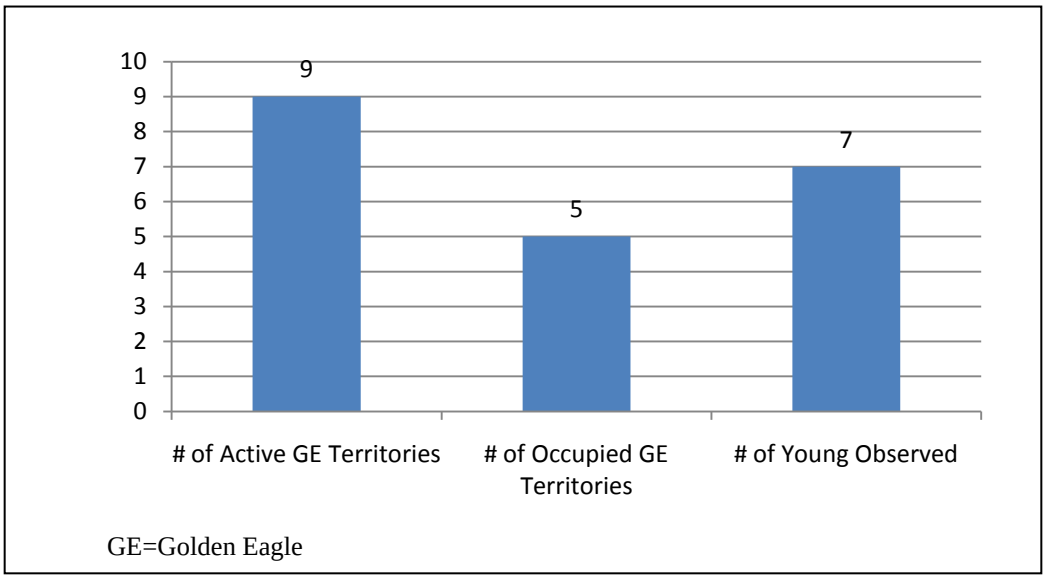

Figure 28. Phase 2 2010 Golden Eagle Territory Data for the Sunrise Powerlink Project.

Table 3 lists the waypoint identification number for each active Golden Eagle nest surveyed during Phase 2, the occupancy status of the nest (i.e., if it is occupied or not), the territory name (incorporating the U.S. Geological Survey Quad [USGS], the USFWS recommended naming convention), and the geographic territory name. Occupied territories are highlighted in yellow.

Territory	Trip ID	Waypoint	Species	Nest Type	# of Young	Occupied Nest	USGS Quad Name	Golden Eagle Territory
4	E	11	GE	SN	2	Y	CA-SD-32116/f5-001-01	Moreno Butte/ Lake Moreno
6	E	8	GE	SN	2	Y	CA-SD-32116/f6-001-01	Barrett/Echo Mtn
7	E	7	GE	SN	0	N	CA-SD-32116/f7-001-02	Lyons Peak
9	E	21	GE	SN	1	Y	CA-SD-32116/g3-001-04	Canebrake

Table 3. Phase 2 - Active Golden Eagle Territories with USGS Quad Territory Names.

SURVEY MAPS BY GOLDEN EAGLE TERRITORY

Active Golden Eagle Territories Surrounding the Sunrise Powerlink Project Area

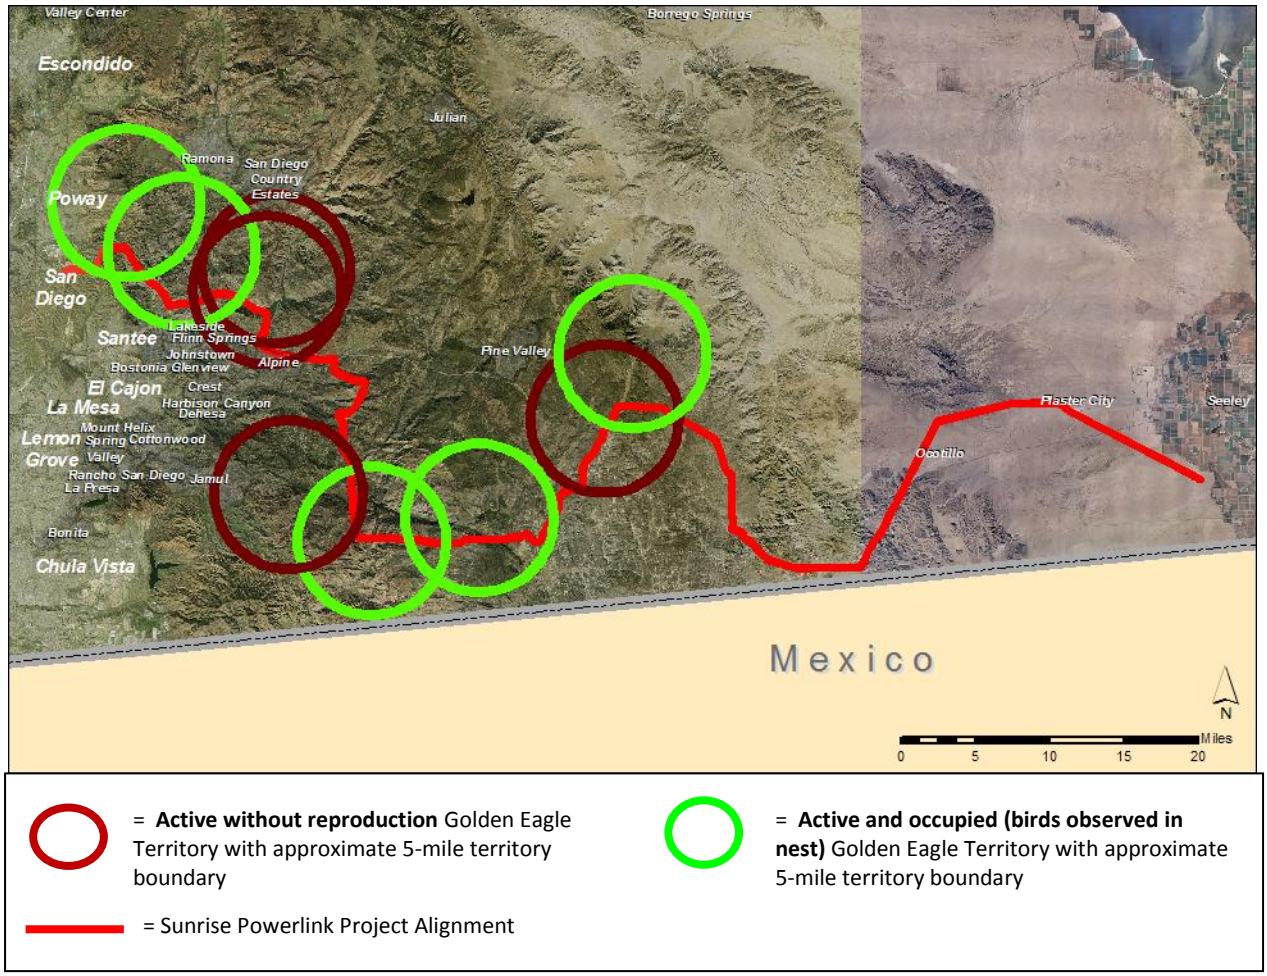

Figure 29. Overview Map of Active Golden Eagle Territories Surveyed During Phase 2.

Overview map of active Golden Eagle territories, with an approximate 5-mile Golden Eagle territory radius (as suggested by USFWS), surrounding the Sunrise Powerlink project area in San Diego County.

Legend for Survey Maps

Figure 30 provides a description of the waypoint labels and abbreviations noted on the following survey maps.

Map Legend	
A50GESN-1	observation ID
A =	trip
50 =	waypoint ID
GE =	Golden Eagle
SN =	stick nest
1 =	one bird/animal present
CR =	Common Raven
GE =	**Golden Eagle**
SN =	stick nest
Helicopter Flight Paths	
=	March 30, 2010
=	April 25, 2010
=	May 14, 2010
=	Occupied territory with An approximate 5-mile radius
=	Active without reproduction territory with An approximate 5-mile radius

Figure 30. Survey Map Legend for Phase 2 Golden Eagle Territory Maps.

Barrett / Echo Mountain

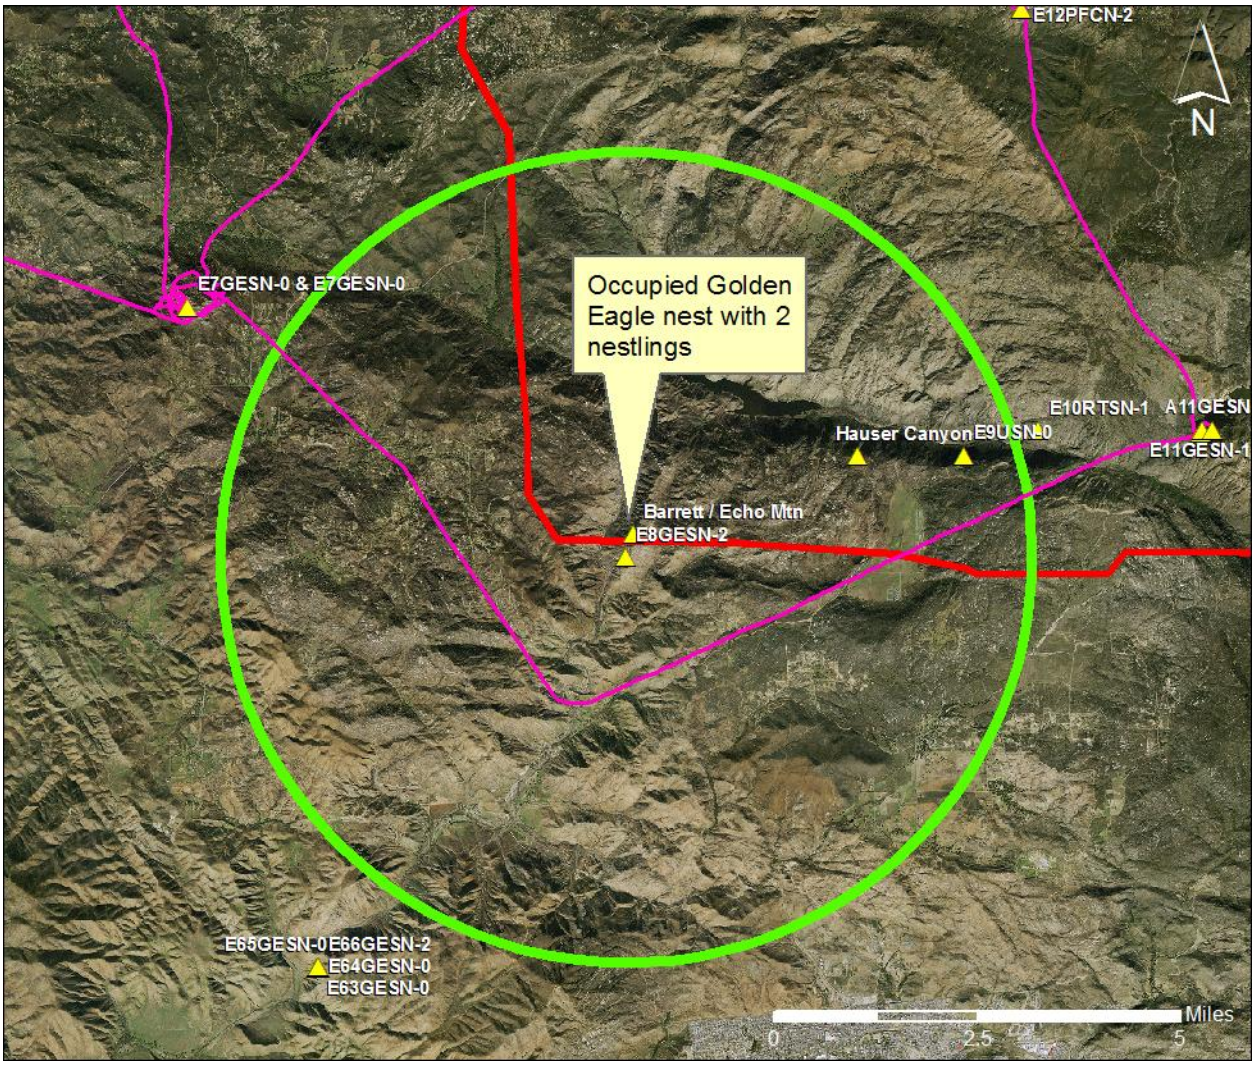

Figure 31. Barrett / Echo Mountain.

Barrett / Echo Mountain, occupied territory. All waypoints for species and nests observed, the helicopter flight path, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

Two nestlings observed in nest during Phase 2 surveys. The nestlings were banded during WRI's annual monitoring and research of Golden Eagle territories in San Diego County, California.

Barrett / Echo Mountain

An active Golden Eagle nest (E8GESN-2) with incubating female observed during Phase 1 surveys, the male was perched nearby.

WRI preparing to retrieve Barrett nestlings from nest for banding (May 9, 2010).

Barrett / Echo Mountain

The older of the 2 nestlings at Barrett Mountain ready to be banded (May 9, 2010).

Collecting routine measurements for WRI's ongoing Golden Eagle research and monitoring (May 9, 2010).

Canebrake

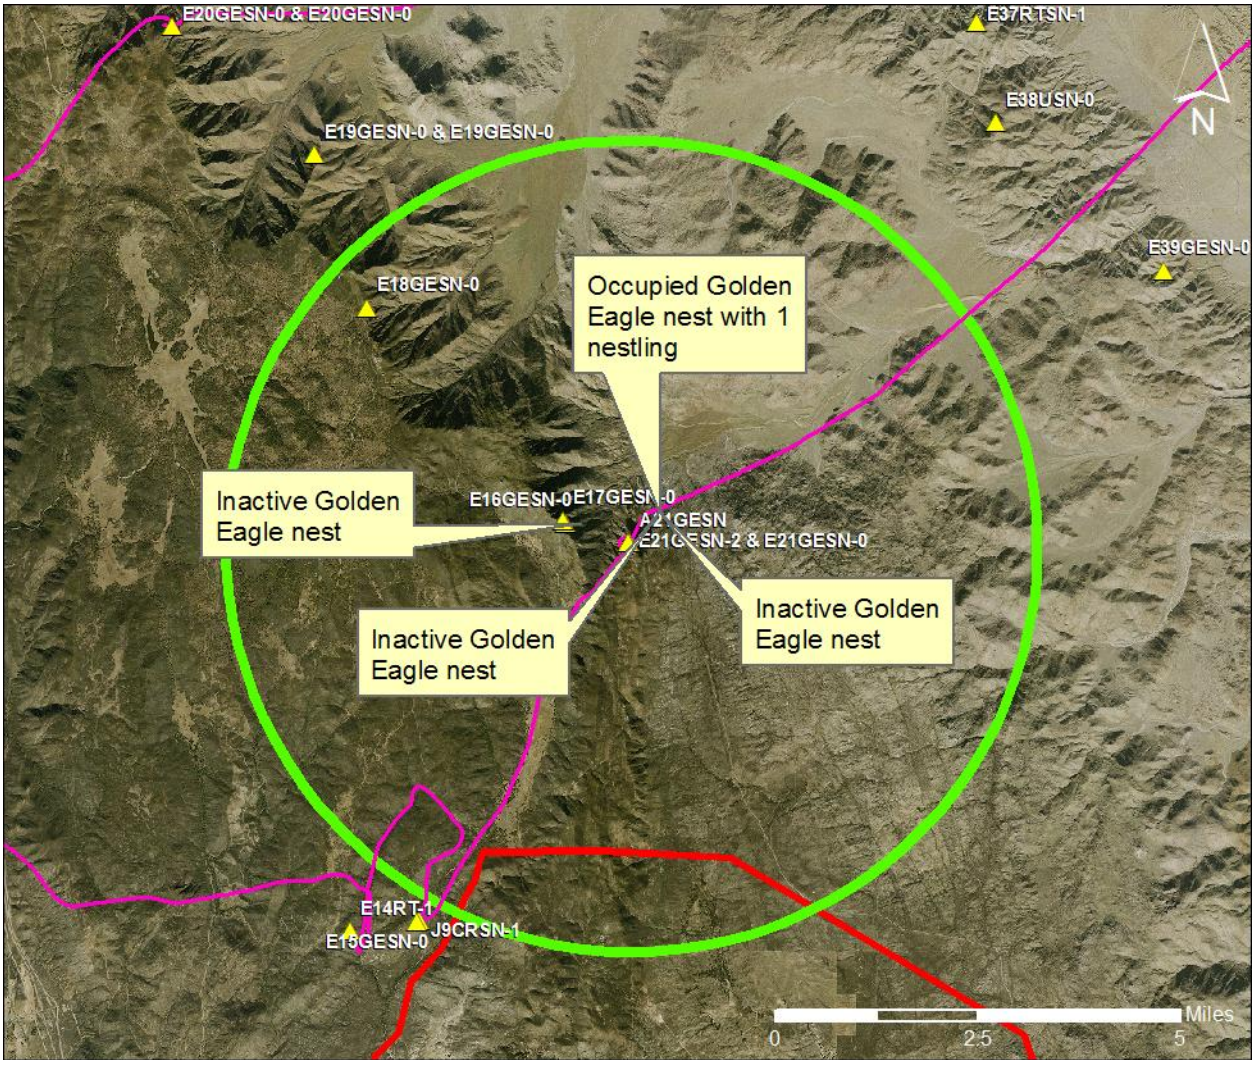

Figure 32. Canebrake.

Canebrake, occupied territory. All waypoints for species and nests observed, the helicopter flight path, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

One nestling observed in nest during Phase 2 surveys that later fledged.

Canebrake

The incubating female (E21GESN-1) observed during Phase 1 surveys on March 30, 2010.

Golden Eagle nestling, approximately 6 weeks of age, can be seen just behind the edge of the bush on right during routine aerial surveys on May 6, 2010.

Canebrake

Female Golden Eagle with nestling, approximately 7 weeks of age, during Phase 2 surveys on May 14, 2010.

View of helicopter approaching Canebrake 2010 nest site during WRI's annual surveys.

El Cajon Mountain

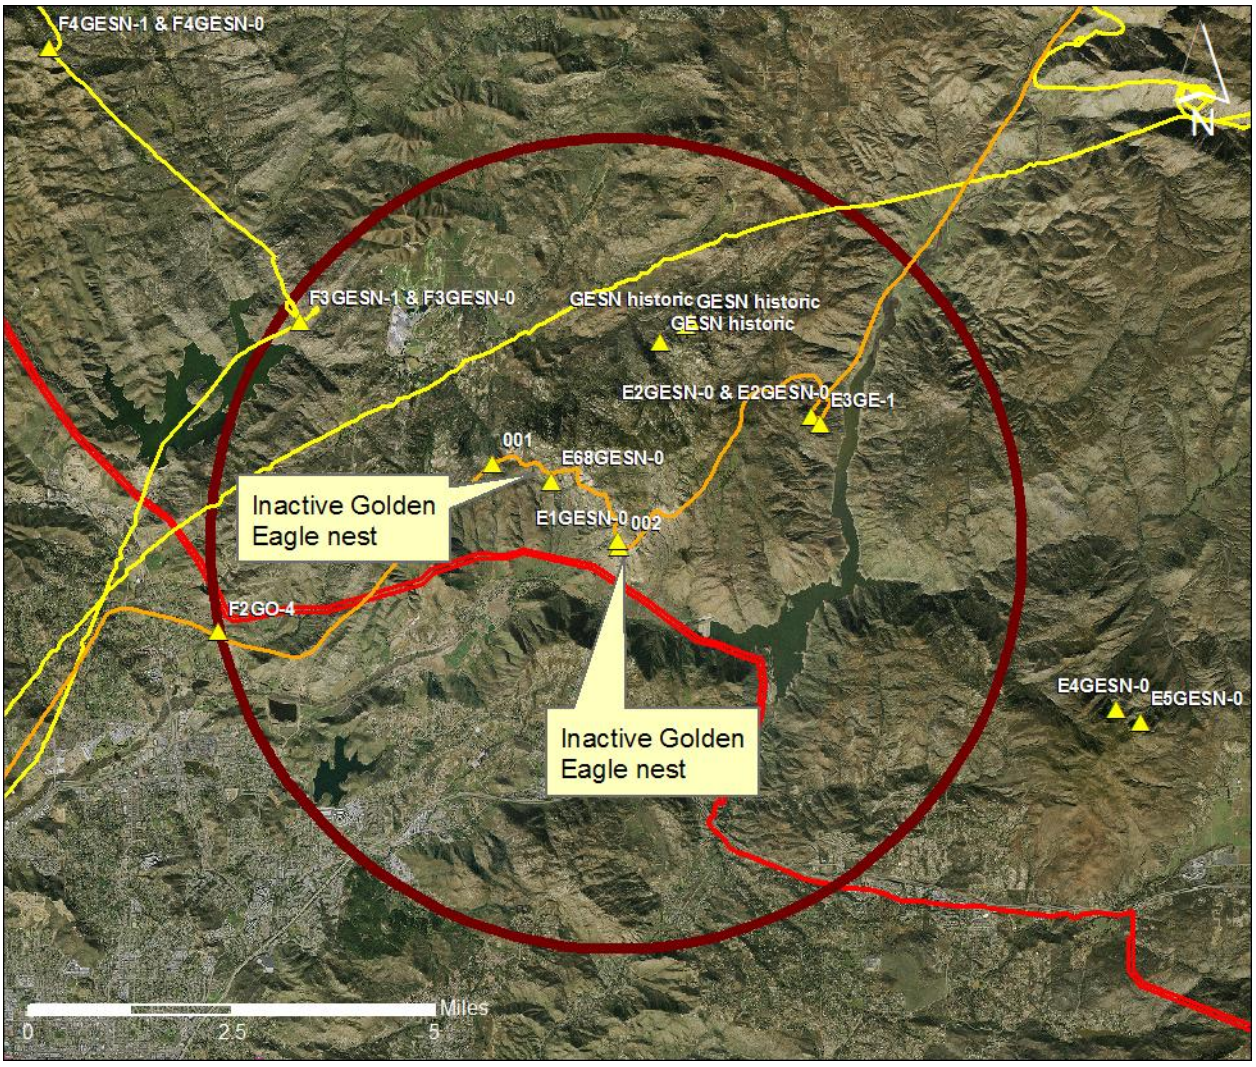

Figure 33. El Cajon Mountain.

El Cajon Mountain, active territory without reproduction. All waypoints for species and nests observed, the helicopter flight paths, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

No Golden Eagles or active nests were observed during Phase 2 surveys.

Iron Mountain

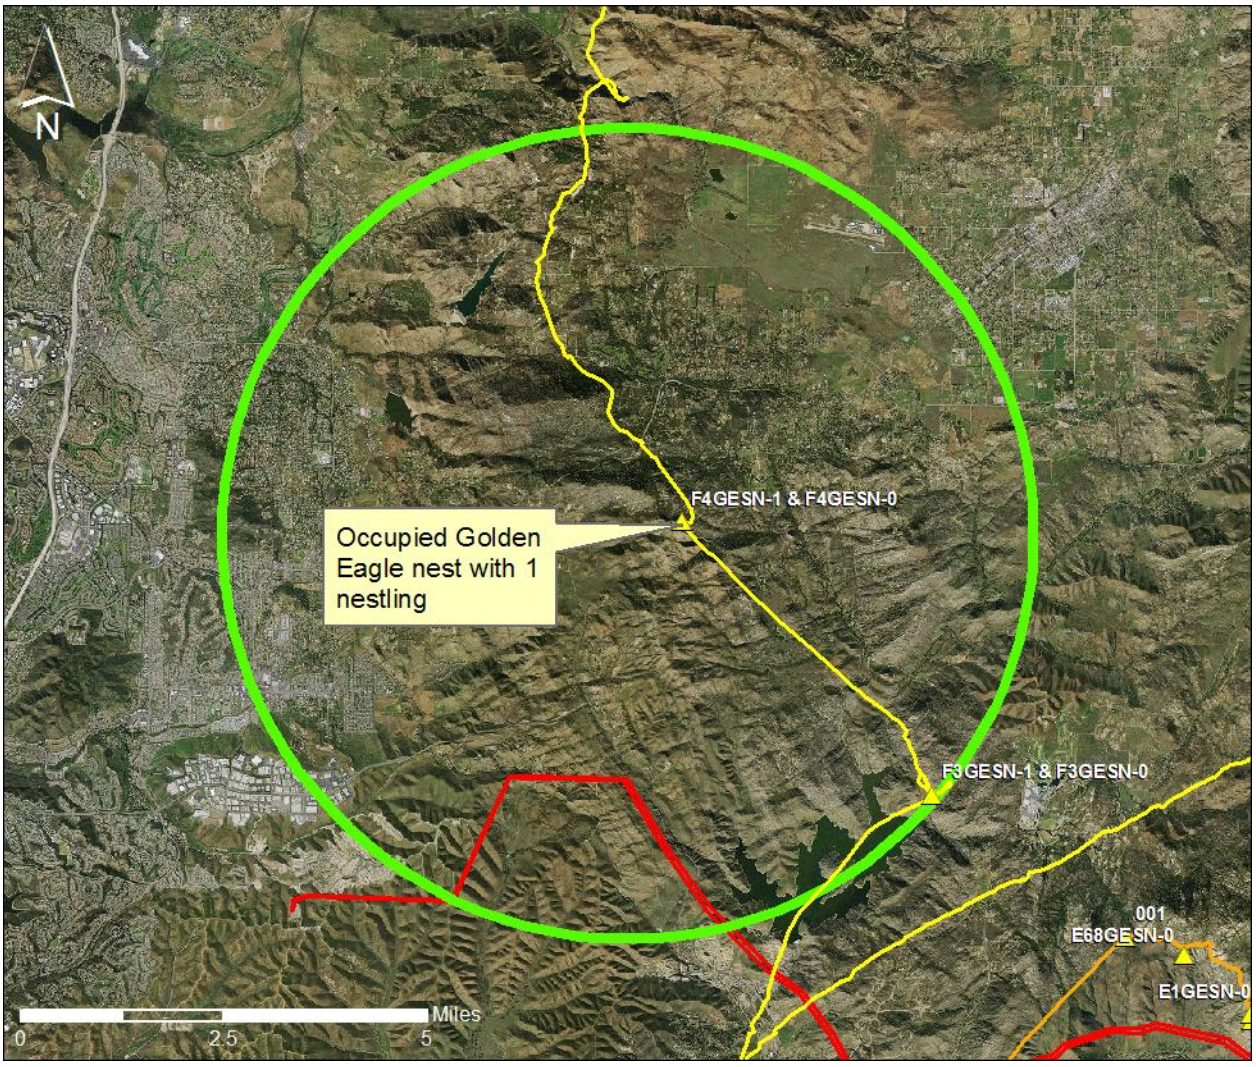

Figure 34. Iron Mountain.

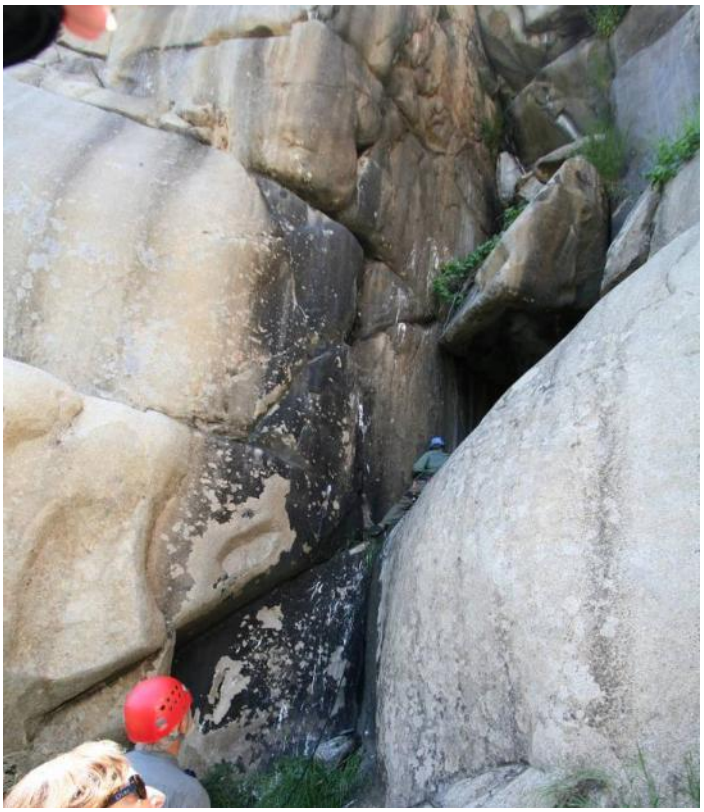

Iron Mountain, occupied territory. All waypoints for species and nests observed, the helicopter flight paths, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

One nestling observed in nest during Phase 2 surveys. The nestling was banded during WRI's annual monitoring and research of Golden Eagle territories in San Diego County, California.

Iron Mountain

Golden Eagle nest (F4GESN-1) observed with a 5 week-old Golden Eagle nestling during Phase 2.

WRI biologist climbing to retrieve Iron Mountain nestling from nest for banding on May 1, 2010, during WRI ongoing research and for Phase 2 surveys.

Iron Mountain

Collecting data on Golden Eagle nestling at Iron Mountain during banding trip on May 1, 2010.

Lake Moreno / Moreno Butte

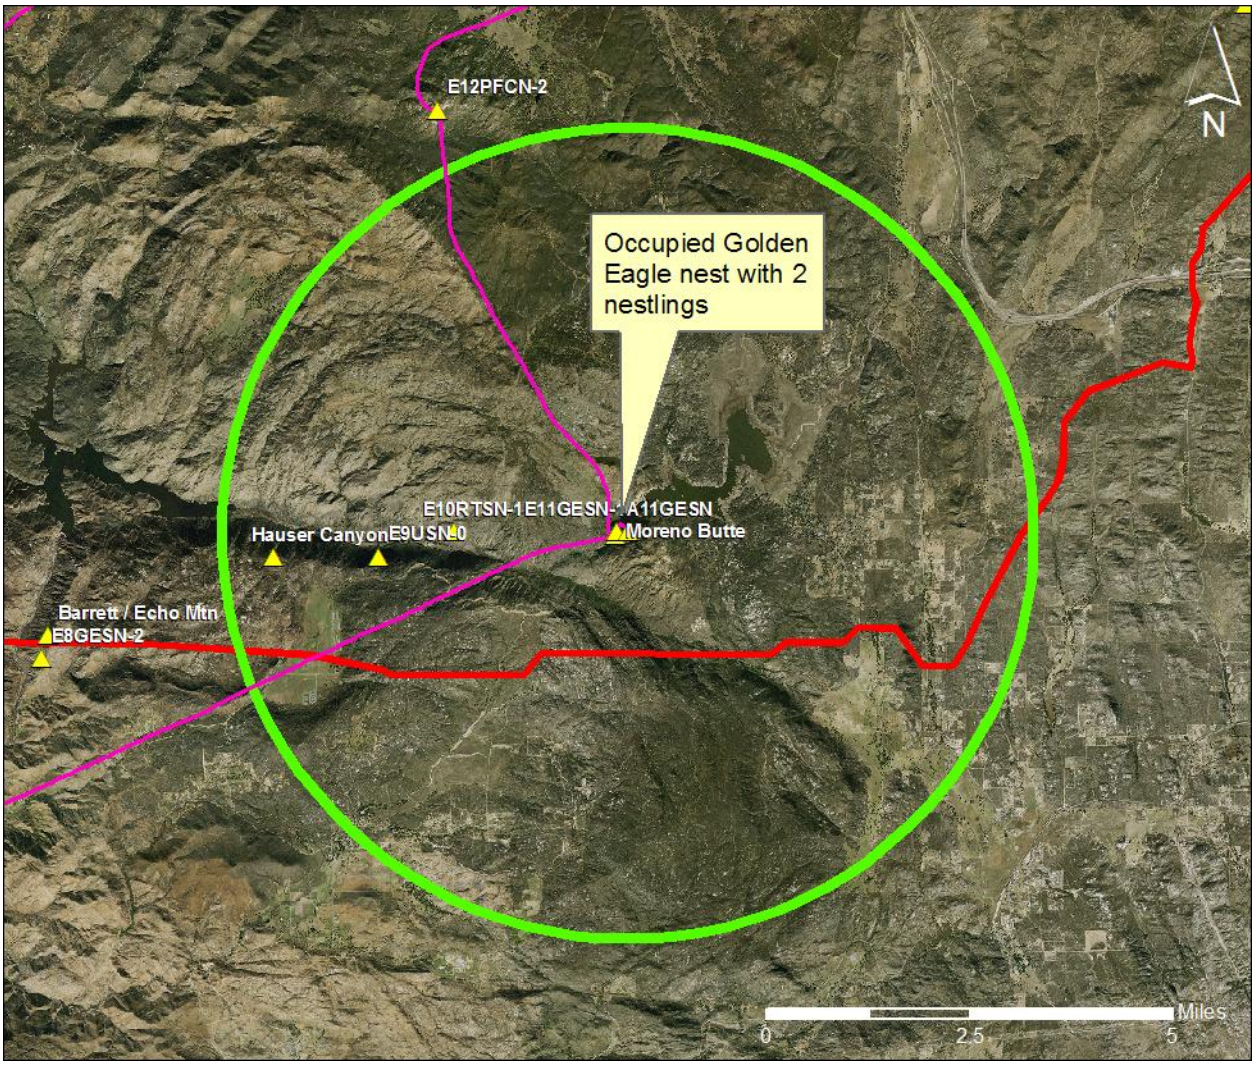

Figure 35. Lake Moreno / Moreno Butte.

Lake Moreno / Moreno Butte, occupied territory. All waypoints for species and nests observed, the helicopter flight path, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

Two nestlings observed in nest during Phase 2 surveys, both were subsequently banded and fitted with satellite transmitters during WRI's annual monitoring and research of Golden Eagle territories in San Diego County, California..

Lake Moreno / Moreno Butte

Incubating female observed during Phase 1 survey on Lake Moreno nest (E11GESN-1) on March 30, 2010.

Two Golden Eagle nestlings, approximately 5 and 6 weeks of age, observed in Lake Moreno nest on May 6, 2010.

Lake Moreno / Moreno Butte

WRI climber approaching Golden Eagle nest at Lake Moreno during annual banding trip, a part of WRI's ongoing monitoring and research of San Diego Golden Eagle territories.

Golden Eagle nestling being retrieved from nest in preparation for banding.

Lake Moreno / Moreno Butte

Applying the satellite transmitter to the first of 2 Lake Moreno / Moreno Butte nestlings.

Lyons Peak

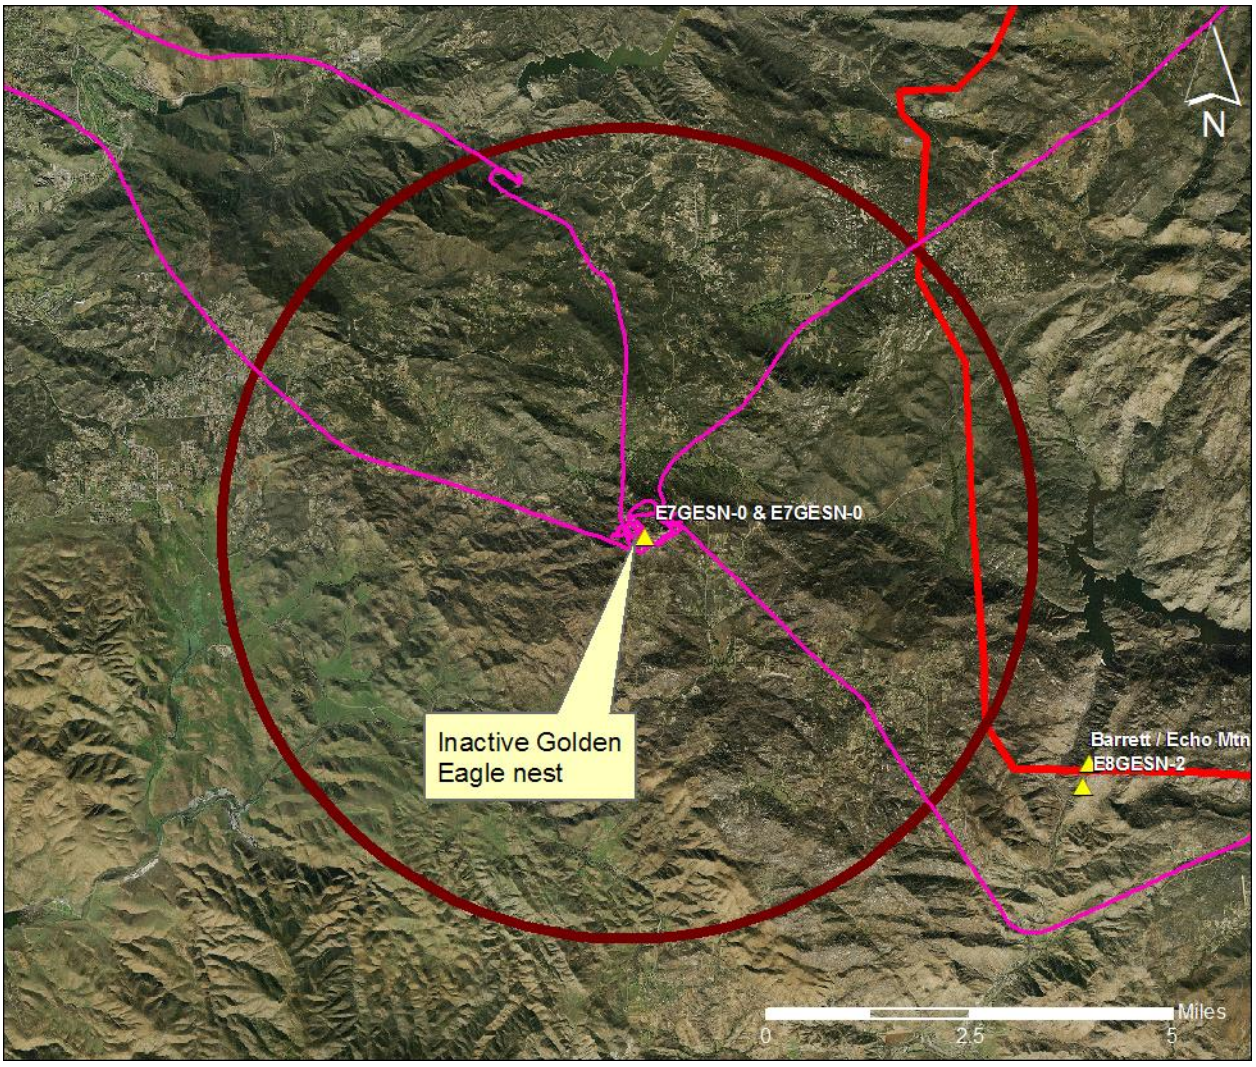

Figure 36. Lyons Peak.

Lyons Peak, active territory without reproduction. All waypoints for species and nests observed, the helicopter flight path, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

No Golden Eagles or active nests were found during Phase 2 surveys.

Rock Mountain

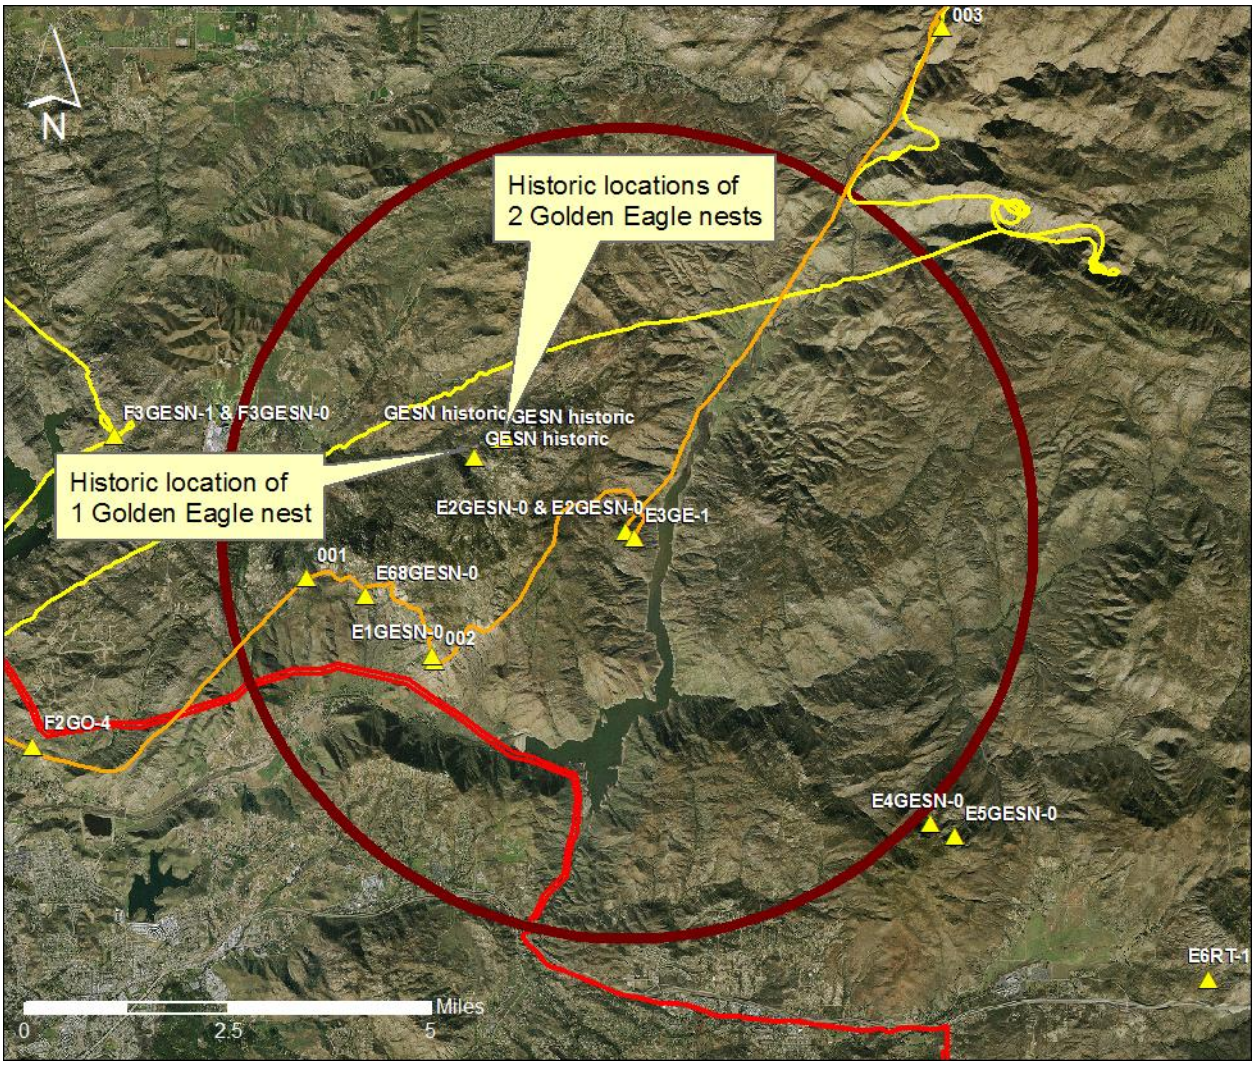

Figure 37. Rock Mountain.

Rock Mountain, active territory without reproduction. All waypoints for species and nests observed, the helicopter flight paths, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

No Golden Eagles or active nests were found during Phase 2 surveys. Historic locations of 3 nests used previously by this pair, but destroyed during the 2007 fires, were surveyed to look for evidence of new activity; no new nest activity was observed.

San Vicente

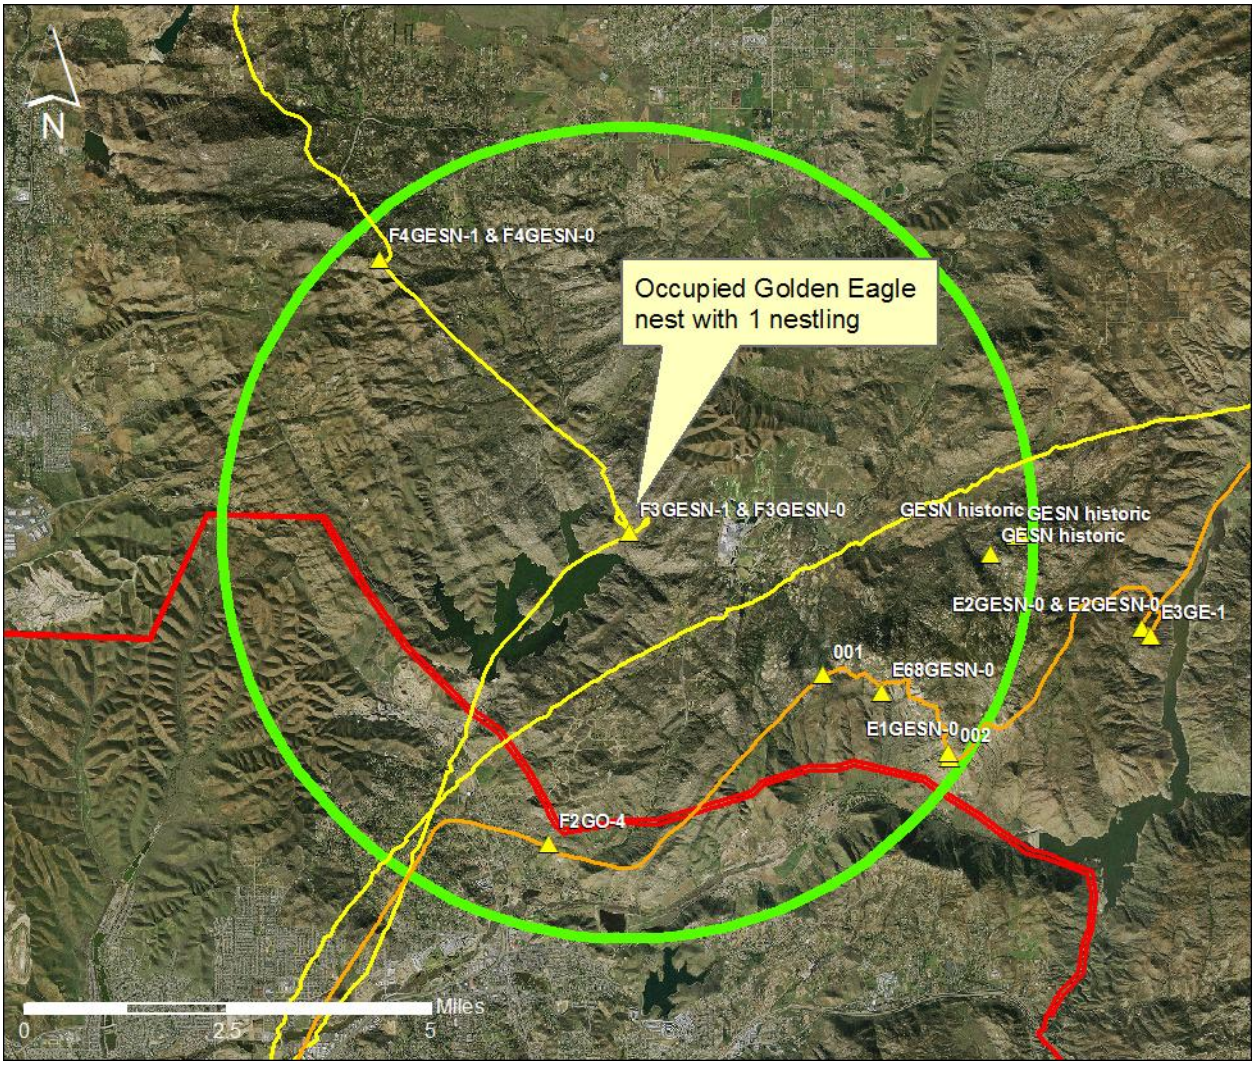

Figure 38. San Vicente.

San Vicente, occupied territory. All waypoints for species and nests observed, the helicopter flight paths, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

Incubating Golden Eagle female and nestling observed during Phase 1 and 2 surveys. The nestling was banded during WRI's annual monitoring and research of Golden Eagle territories in San Diego County, California.

San Vicente

An active Golden Eagle nest (F3GESN-1) with a 5 week-old Golden Eagle nestling observed during Phase 2 surveys on April 25, 2010.

Golden Eagle nestling from San Vicente territory (F3GESN-1) banded during Phase 2 surveys on May 2, 2010, and as part of WRI's annual research of territories in San Diego County.

Thing Valley

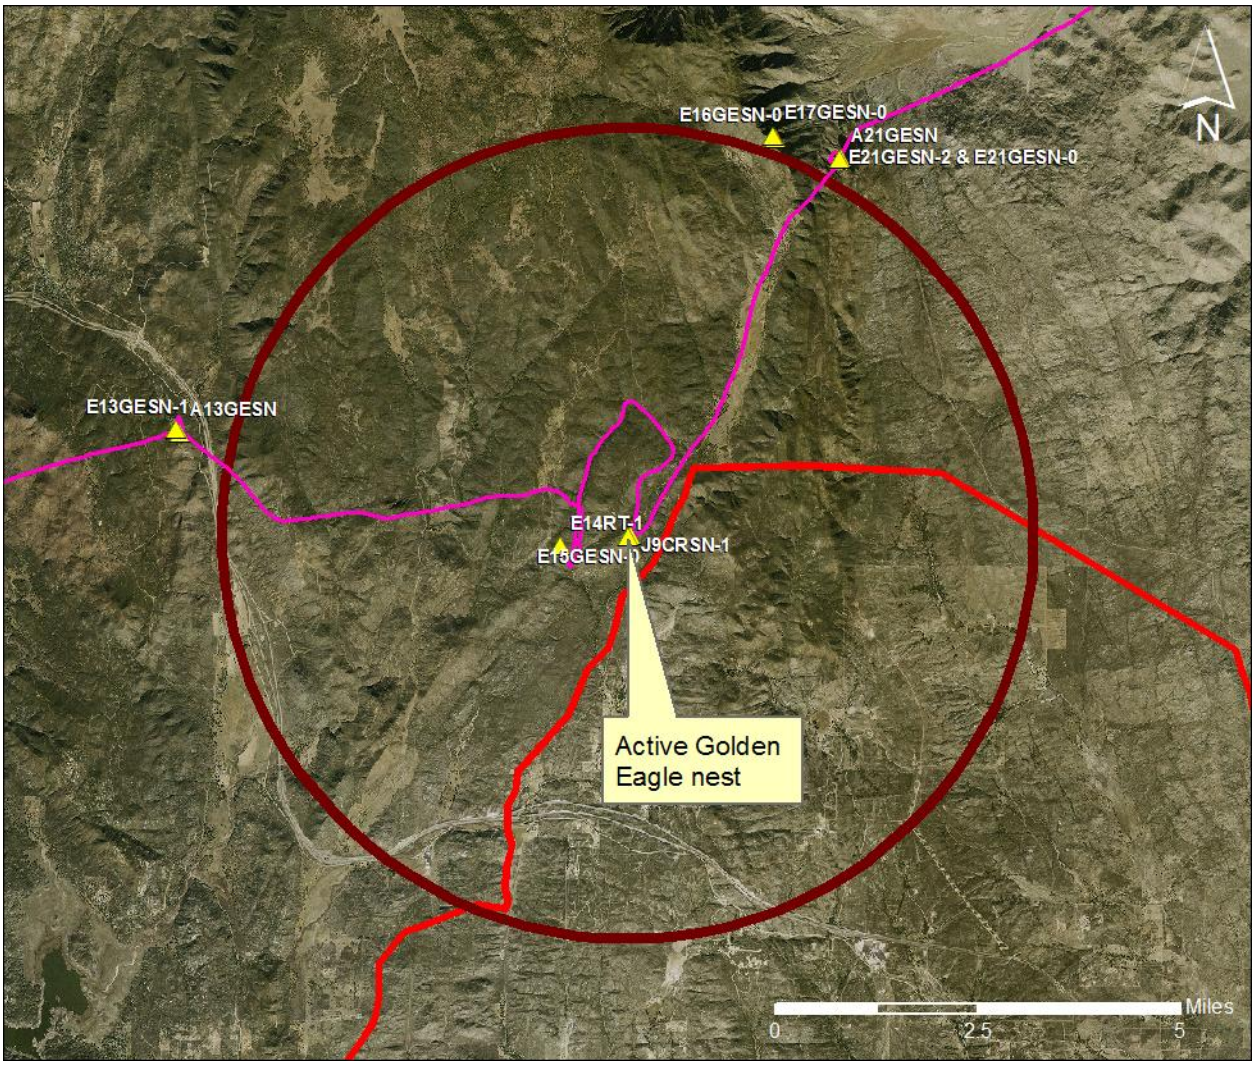

Figure 39. Thing Valley.

Thing Valley, active territory without reproduction. All waypoints for species and nests observed, the helicopter flight path, Project alignment, and an approximate 5-mile Golden Eagle territory radius are provided.

No Golden Eagles observed during Phase 2 surveys.

DISCUSSION OF FINDINGS

During Phase 2 surveys, we revisited 9 of the 19 territories because there were indications that breeding activity may be occurring in the territory during Phase 1. Five of the 9 territories resurveyed actually produced 7 baby eagles. The five productive territories were Barrett/Echo Mountain (2 young), Canebrake (1 young), Iron Mountain (1 young), Lake Moreno/Moreno Butte (2 young), and San Vicente (1 young).

Part of WRI's annual studies on San Diego's Golden Eagles includes banding and tagging the young to learn more about their behavior and survival. Six of the 7 young from these nests were banded and tagged with Very High Frequency (VHF) transmitters and 2 of these eaglets, from Moreno Butte, were also fitted with satellite transmitters. This satellite transmitter data along with the VHF data may be useful in determining the usage of the territories as it relates to energy projects.

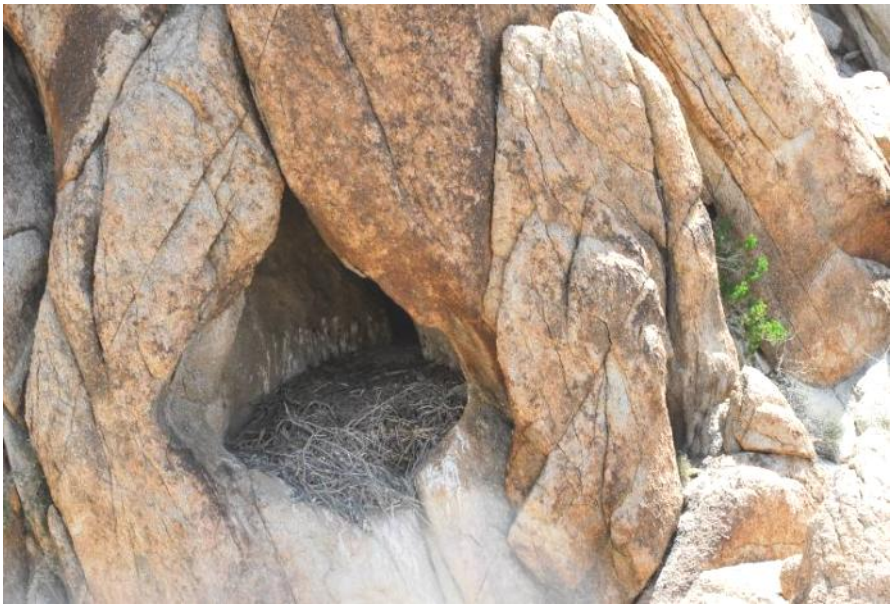
APPENDIX B: Glossary of Golden Eagle Nest Terms



NEST CONDITION

Good condition - A Golden Eagle nest in **good condition** has been worked on in the current year or within the past 1 to 3 years; a determination made by observing the age of sticks or recent addition of other materials that make up the nest. Additionally, the presence of a bowl constructed with yucca, with or without new material, is indicative of recent activity and good condition.

Good condition

Fair condition – A Golden Eagle nest in **fair condition** has not been used for several years, shows moderate signs of weathering, and may include a rough bowl.

Fair condition

Poor condition – A Golden Eagle nest in **poor condition** shows strong signs of weathering, is in the process of deteriorating, and can often even be decomposing.

Poor condition

NEST ACTIVITY

Active nest - An **active nest** is a nest in good condition that has evidence of new material having been added during the season in which the survey has been conducted. It will include the use of yucca and often includes the construction of a bowl, used for incubation. An active nest may or may not be **occupied** by a Golden Eagle (e.g., an incubating female or a young bird) at the time of survey.

Occupied nest – An **occupied nest** is an active nest in which an adult or young Golden Eagle, or a new egg, has been observed during the survey.

NEST ARRANGEMENT

Multiple nests at one waypoint – Golden Eagles often construct nests in close proximity to one another. During surveys, these nests are often recorded at a single waypoint.

APPENDIX C: WRI Golden Eagle Team Biographies

Dave Bittner
Executive Director, WRI
Wildlife Biologist/Raptor Ecologist

Mr. Dave Bittner is a Co-founder and Executive Director of The Wildlife Research Institute, Inc. and has been a Wildlife Biologist for more than 44 years. Much of his work has been with raptors of various species but he has also studied and banded 3700 Great Blue Herons, conducted mammal research, and trapped and tagged over 3,000 mammals of various species. Dave currently coordinates an annual Golden Eagle and raptor population study throughout Southern California, including the Western Mojave Desert and the Anza-Borrego Desert State Park. He is the Primary Investigator (P.I.) for the Southern California Golden Eagle Population Study, the longest continuous running (22 years) Golden Eagle study of its kind in the Western Hemisphere, which began in 1968. Currently, he is also the P.I. for WRI's satellite and VHF telemetry-based Golden Eagle migration and habitat use study in cooperation with the US Forest Service, Montana Parks and Wildlife, and the California Department of Fish and Game. WRI, under Dave's direction, has conducted annual helicopter surveys on Golden Eagles and raptors in general since 1996. Dave has banded raptors since 1963 and has banded over 420 Golden Eagles, many with VHF and satellite telemetry. He has conducted Bighorn Sheep surveys, both aerial and ground, for Desert Bighorn Sheep in the Mojave Desert and for Peninsular Bighorn Sheep in the Anza-Borrego Desert State Park and Baja, Mexico since 1998. Dave has also surveyed Bighorn Sheep in Montana where WRI has a research Station. His education includes a B.Sc. in Zoology and Wildlife Management from Ohio State University (1968). He also conducted graduate studies in Avian Reproduction and Natural Resources (1975-1977) at Ohio State University. Dave has worked for the U.S. Fish and Wildlife Service, Cleveland Museum of Natural History, and the Ohio Department of Natural Resources and has taught at two universities and one technical college.

Jeffrey L. Lincer, Ph.D.
Research Director, WRI
Senior Scientist/Wildlife Biologist/Raptor Ecologist

Dr. Lincer is a Co-founder and Research Director of The Wildlife Research Institute, Inc. and has extensive experience surveying for raptors, including helping establish WRI's Montana Raptor Migration Station. He has actively participated in the institute's Southern California Golden Eagle project since 2000, including helicopter surveys since 2001. He has conducted numerous raptor surveys for federal, state, county, and local governments, and the private sector across desert and mountain habitat in the California Mojave and Anza-Borrego deserts, San Diego County, Nevada and the mountains of northern Baja Mexico. In addition, Jeff has over 100 hours of aerial surveying for Bald Eagles and over 50 hours for fish-eating birds. He has conducted Bighorn Sheep surveys, both aerial and ground, in the Mojave Desert and for the Anza-Borrego Desert State Park since 1998. Dr. Lincer's background includes 40 years as a scientist, scientific advisor, and administrator in the environmental research and management areas. He has taught college level courses in environmental and occupational health, environmental science, ornithology, and mangrove ecology, produced over 100 scientific publications and papers (most on raptors), authored dozens of environmental reports, and served as advisor to high-level governmental offices and national/international conservation programs. Jeff received his Bachelors and Masters degrees in Wildlife Biology/Wildlife Management

from Syracuse University and his Doctorate in Ecology and Toxicology from Cornell University. He is most well known for his work with raptors and other threatened/endangered species and his ability to manage complex interdisciplinary projects and work productively with government agencies. He is a Past-President of the Southern Chapter of The Wildlife Society. As President of the Raptor Research Foundation (RRF) from l982 to l988, he oversaw the greatest growth of that professional organization in its entire history. He chairs RRF's Leslie Brown Award Grant Committee (for research on African raptors) and chaired the First International Burrowing Owl Symposium and Workshop. He is the Co-editor for the Proceedings of the First International Symposium on Burrowing Owls, a Co-editor of the proceedings of the First California Burrowing Owl Symposium, and is a contributing Technical Editor for a recent book on California's endangered species. Dr. Lincer was the founding Director of the National Wildlife Federation's (NWF) Raptor Information Center. During his NWF tenure, he coordinated with government agencies and the private sector, developed computerized literature databases, and prioritized eagle and other raptor habitat throughout the United States for acquisition. He served as Consulting Editor for the joint RRF/Bureau of Land Management publication, "Raptor Habitat Management Multiple Use Mandate." Over the last four decades, he has worked on major projects from Alaska to Africa, addressing raptor population trends, ecological monitoring, environmental impacts, ecotoxicology, and habitat protection and acquisition.

Chris Meador
WRI Assistant Director
Wildlife Biologist

Mr. Meador is a full-time Wildlife Biologist for the Wildlife Research Institute (WRI) and has been a Wildlife Biologist for the past eight years. Chris has three years experience conducting helicopter surveys on Golden Eagles and other raptors, including over 125 hours of helicopter survey experience. He has conducted numerous raptor surveys for federal, state, county and local governments, and the private sector across desert, coastal and mountain habitats. He co-leads WRI's Southern California Golden Eagle Population Study, the longest running study of its kind in the Western Hemisphere and has participated in it for the past ten years. He currently carries out myriad tasks for various projects pertaining to the Golden Eagle. These include trapping, tagging, and affixing radio and satellite telemetry transmitters to nestling, juvenile and adult Golden Eagles in San Diego County as well as migrating Golden Eagles in Montana. He maintains and oversees much of the Wildlife Research Institute's tracking process including gathering, interpreting and publishing data and findings using GPS and GIS integration. Chris has conducted Bighorn Sheep surveys, both aerial and ground, in the Mojave Desert and for the Anza-Borrego Desert State Park since 2008. He has assisted with projects, including research, education and reintroduction on a broad range of species from endangered mammals to sensitive fish and from Burrowing Owls to Desert Tortoises. Mr. Meador also conducts educational programs on multiple topics including natural history, ecology and conservation pertaining to many different species. He is an expert in identification and ecology of North American raptors. He holds a Bachelor of Arts degree with a double major in Environmental Studies and Psychology from Prescott College in Prescott, Arizona.

Renée Rivard, Pharm.D.
Wildlife Biologist

Dr. Rivard is currently a member of the Wildlife Research Institute's Golden Eagle team; she has participated in all of WRI's 2010 Golden Eagle surveys conducted for numerous renewable energy projects across desert and mountain habitat in the California Mojave desert, San Diego County, and Nevada. Renée has over 25 hours of experience conducting Golden Eagle helicopter surveys. In addition to participating in aerial transect surveys and ground surveys to identify Golden Eagle nests and territory impacted by renewable energy projects, she has also participated in WRI's ongoing Golden Eagle research and monitoring project in San Diego County as a member of the banding and telemetry teams. She maintains the Golden Eagle Database and helps maintain Burrowing Owl artificial burrows on premises at WRI headquarters and continues to expand her knowledgebase related to these and other raptors. Renée assists with WRI's annual Hawk Watch educational program about the Ramona Grasslands and its raptor residents and migrants. Her 20+ years of database, scientific publishing, and medical research experience provide her with the background and skills to efficiently and professionally assimilate survey data for WRI, clients and agencies. Over the last 4 years, she has accumulated diverse and valuable wildlife knowledge and skills as a wildlife rescuer, rehabilitator, and veterinarian assistant for non-profit organizations in Australia and, more recently, as a field technician and laboratory technician for the San Diego Zoo's Institute for Conservation Research Applied Animal Ecology Department and Wildlife Disease Laboratory, respectively. Renée received her Bachelor's of Science in Biology from the University of South Alabama (1987), graduated *cum laude* with her Doctorate of Pharmacy from Creighton University (1995), and completed specialized post-graduate papers in medical literature evaluation from the University of Auckland in New Zealand (2001).

Leigh Bittner
Vice-President, WRI
Field Assistant

Mrs. Bittner first flew Golden Eagle helicopter surveys in 1996. She has participated in Golden Eagle nest surveys, eagle banding, tagging and tracking in California since 1991, New Mexico, 2001 and Montana since 2000. Leigh has also been involved in tagging and releasing of some of the first California Condors in California, 1992, and Arizona, 1996. Leigh is a co-founder of the Wildlife Research Institute, Inc. and has been a Board member since 1996. She is a retired Marketing Manager from Hallmark Corporation and helps coordinate office operations to support WRI's field activities.

Brittany Schlotfeldt
Wildlife Biologist

Ms. Schlotfeldt has experience with mammals and birds and field transect experience in both the marine and desert environments. Brittany has one year experience conducting helicopter surveys of Golden Eagles and other raptors. She assisted with the research on coral recruitment across various conditions in Hawaii (Donald Potts Lab, UCSC) and tracked sea otters for SORAC (Sea Otter Research and Conservation) at the Monterey Bay Aquarium. Brittany has also assisted with, and performed, a number of tasks in the upland and desert habitats for various Wildlife Research

Institute (WRI) projects. In the desert environment, she has assisted with WRI's research on golden eagles (radio telemetry and tracking), burrowing owls (transect surveys, field observations, trapping, and banding), and desert tortoises (surveyed over 100 miles of protocol transects in the Western Mojave Desert with Drs. Boarman and Lincer, and Mr. Peter Woodman). This study, which was recently completed, was a follow-up on an earlier project focused on the potential impacts of vehicular traffic, and highway fencing, on tortoise mortality (Boarman and Sazaki 2006). She has additional experience with desert tortoises on Fort Irwin, where she conducted numerous surveys and assisted with the VHF-transmittering of tortoises in an effort to relocate the individuals. Ms. Schlotfeldt received her Bachelor's of Science in Marine Biology from the University of California, Santa Cruz (2008).

James Hannan, Ph.D.
Senior Wildlife Biologist

Dr. Hannan has seven years experience with WRI conducting helicopter surveys of Golden Eagles and other raptors. Jim also helps on WRI's long running Golden Eagle Research project with rappelling to, banding and tracking Golden Eagles. He is fluent in Spanish and served as an International Environmental Consultant for the Peace Corps and United Nations Volunteer programs His professional experience includes two years as a Peace Corps Volunteer (fisheries and agriculture, in Panama), one-year Peace Crops staff (fisheries development in Puerto Rico), and one year at the Smithsonian Institution. His academic experience also includes three years as Professor of Marine Biology and Environmental Studies at Florida Institute of Technology. Jim also spent twelve years as a private environmental consultant (contracts included Mexican aquaculture, impacts to Caribbean coral reefs, deer and other game studies involving radio transmitters for the California Dept of Fish and Game). He also served as a Texas game ranch manager, naturalist for East Africa wildlife filming company, fishery management advisor for the Florida Keys and holds a NAUI diver certificate and Florida EMT certificate. Dr. Hannan, is a WRI Senior Wildlife Biologist and Professor, Mesa College. He received his BS in 1965 from Humboldt State University, his MS in 1969 from University of Oregon, and his PhD in 1973 from the University of Miami (FL).

Jeff Wells
Wildlife Biologist

Mr. Wells has been involved with WRI's Golden Eagle research since 1991 including trapping, banding and tracking. Jeff has ten years experience with WRI conducting helicopter surveys of Golden Eagles and other raptors. He has his Bachelors in Wildlife Studies from San Diego State University and has over 20 years experience as a private wildlife biologist. For the past 5 years, Jeff has been a Wildlife Biologist for the US Forest Service.

James Newland
Field Biologist

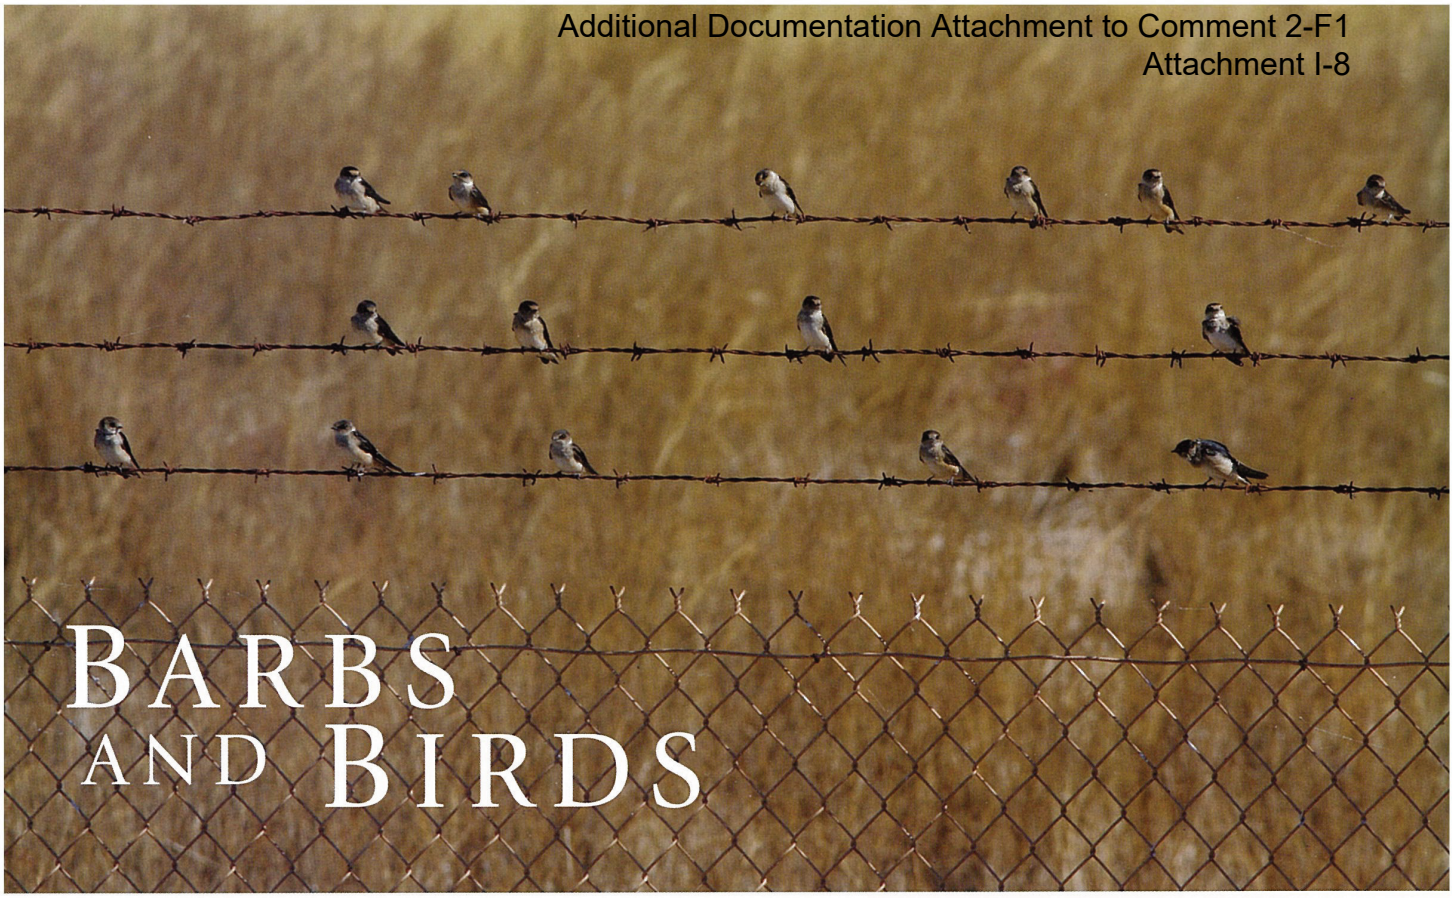
Mr. Newland has assisted WRI on Golden Eagle research for the last 4 years banding, trapping, and VHF and satellite tracking. James has also assisted trapping and tracking Golden Eagles at

WRI's migratory research center in Montana. He has one year experience conducting helicopter surveys of Golden Eagles and other raptors. James has a Bachelor's of Science in Electrical Engineering and has worked for numerous large communication corporations.

Jeff Laws
Field Biologist/Bio-climber

Mr. Laws has assisted WRI with Golden Eagle research and field work since 1995. He has also assisted trapping and tracking Golden Eagles at WRI's migratory research center in Montana. Jeff has five years experience conducting helicopter surveys of Golden Eagles and other raptors with WRI. Jeff works as a climber and field installer for San Diego Gas & Electric Company.

Mel Cain
Utility Helicopters



Mr. Cain has more than 55 years experience flying helicopters for wildlife surveys. Utility Helicopters, with their Hughes-500 helicopters, has assisted WRI in Golden Eagle and raptor surveys for the last 10 years in the United States and Mexico. Mel has 12 years of experience in New Zealand trapping and transporting big game including deer and elk. He has conducted hundreds of netting and translocations of Bighorn Sheep and Tule Elk in California for California Fish and Game and California State Parks. Mel works frequently in Mexico and Canada and maintains NAFTA and Mexican permits to conduct wildlife and resource surveys.

Gregg Matson, M.D.
Cherry Helicopter

Dr. Matson is a practicing physician who also started and headed a helicopter company in Hawaii to provide industrial and tourist services. Cherry Helicopter uses Hughes-500 helicopters to conduct these surveys. Gregg, WRI, and Cherry Helicopter have conducted wildlife surveys both in the United States and Mexico. He has supported WRI in aerial helicopter surveys of Golden Eagles, raptors and other wildlife for the last 8 years.

Barry Martin
Western Tracking Institute

Mr. Martin is a WRI Research Associate and Director of the Western Tracking Institute. He has a Bachelor's in Business from Fresno State and an Associate's degree in Aeronautics. He has 42 years of flying experience and 22 years in the Navy with over 300 aircraft carrier landings. Concurrent with his Navy experience, he flew for over 21 years as a pilot for American Airlines. In total, Barry has over 20,000 hours of experience in the air. In 1989, Barry started the San Diego Tracking Team and started the Western Tracking Institute in 2007 to further expand his studies in wildlife populations and movements. In 2006, he started VHF tracking from aircraft primarily for mountain lions and 2 years later, began assisting WRI in aerial VHF tracking of Golden Eagles.

BARBS AND BIRDS

Barbed wire snares many a bird, but the toll can be lessened

BY CAROL BOOTH

Clockwise from above:

Like notes on a page Tree Martins punctuate a barbed wire fence at Port Headland Sewage Works Western Australia. Birds as small as this rarely come to grief on the barbs, but they can fatally snag unlucky larger birds. Photo by **Rohan Clarke**

Barn Owls are among the most vulnerable of night flying birds to entanglement on barbed wire fences. Photo by **Rohan Clarke**

Even plain wire can be a trap for unlucky large, terrestrial animals. This photograph, taken in 1911, shows the remains of an Emu on a property in north-west New South Wales. The associated notes state: 'The unfortunate bird could not get away from this grip—it died no doubt of *thirst* and *starvation*. It will be noticed that the leg resting on the ground has made a hole underneath, through the bird kicking and struggling in its efforts to escape.' Photo by **Sidney Jackson** courtesy of the National Library of Australia

THE DEVIL'S ROPE recently snagged a rare beauty when a Night Parrot encountered something alien, barbed and final.

The discovery in September 2006 of a headless Night Parrot, killed by collision with a barbed wire fence in far western Queensland, made national news. After all, it was 17 years since the endangered bird was last definitely seen—that one also dead, hit by a vehicle. Prior to that, the survival of the Night Parrot hadn't been confirmed for 80 odd years.

The Night Parrot was a rare and famous victim of one of the cruellest hazards for wildlife. For some bats and gliders barbed wire is a recognised conservation threat. For other species, it is an occasional hazard, and a really horrible way to die. All up, there are reports of more than 70 species being found entangled in barbed wire fences in Australia, including about 50 birds.

While barbed wire was for a long time considered to be the only way to control stock, in most circumstances there are now other effective, including cost-effective, fencing choices. In this article I put the case for adopting other forms of fencing, for the sake of wildlife conservation and animal welfare. I also seek the help of birders in reporting information about wildlife entanglements, and landowners in assessing the effectiveness of wildlife-friendly fencing.

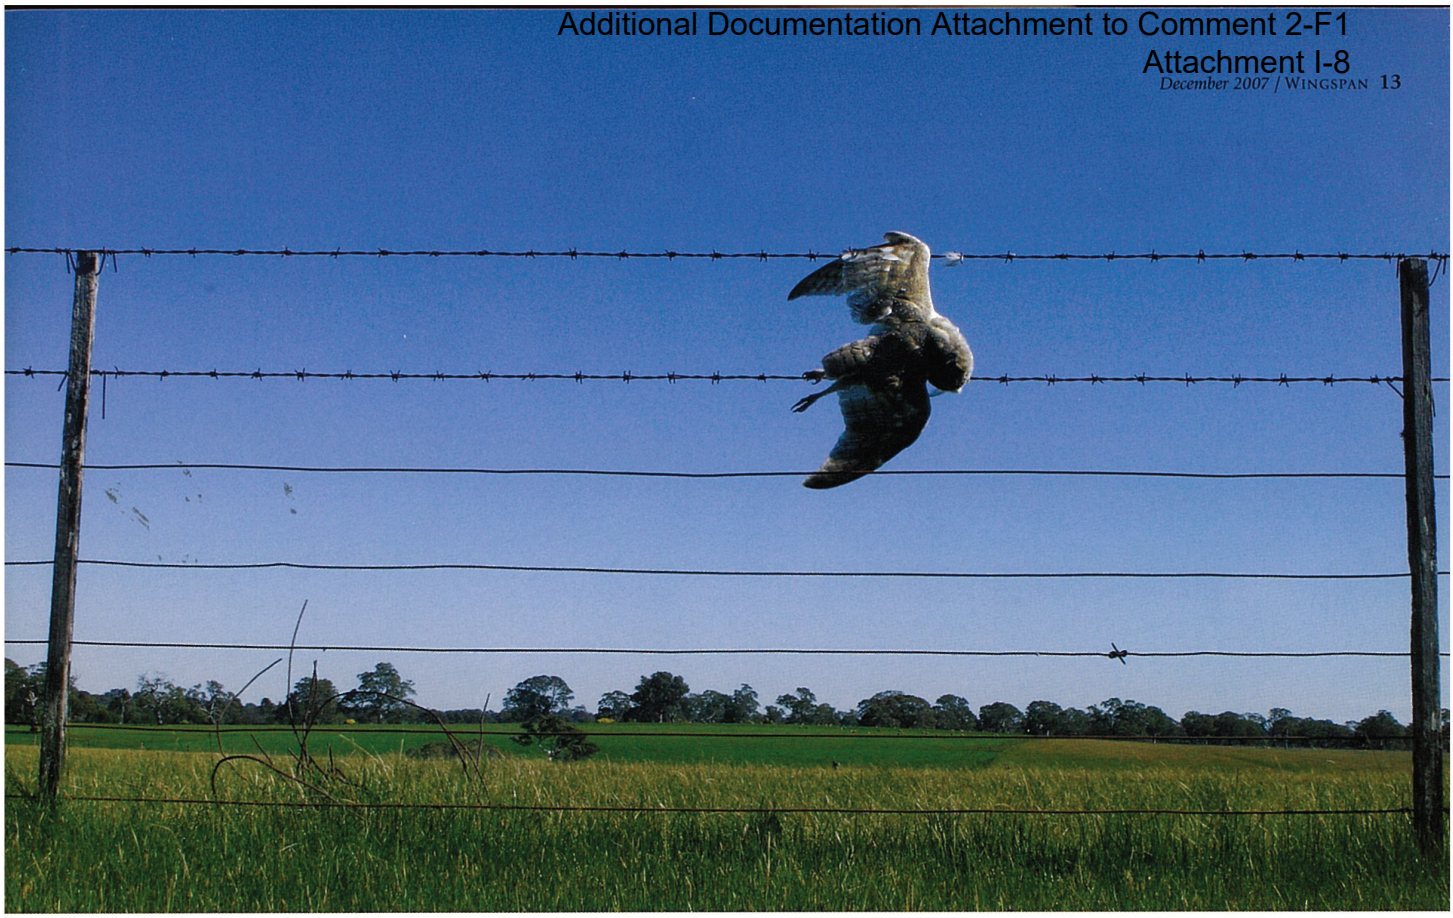
Barbed history

The invention of barbed wire was based on the well-founded principle that animals quickly learn to avoid that which inflicts pain.

Although it was invented several times, initially in France, barbed wire fencing took off on a large-scale with an 1874 patent by a US farmer. More than 600 different patents followed.

In North America, barbed wire was apparently cursed as the devil's rope (or hatband) by Native Americans cut off from traditional hunting grounds (and hindered in night raids on cattle) as well as by free-ranging cattlemen excluded from waterholes. The new barbed forms of fencing initially provoked loud protest—mainly because of injuries to horses and cattle, and the loss of access to water. In the Texas fence-cutting wars in the 1880s, gangs such as the Blue Devils and The Owls fought with cutters to keep the ranges open.

As a cost-effective way of carving up rangelands into paddocks, barbed wire fencing ushered in a rapid transformation of savannas and grasslands all over the world. By the early 1900s, for example, the Argentinean pampas was crisscrossed with enough barbed fencing to encircle the entire republic an estimated 140 times.



In Australia plain wire fencing had already done most shepherds out of jobs, says fencing historian John Pickard. Barbed wire became the norm soon after it became available here in the late 1800s.

By fencing off paddocks, as well as developing water points and ringbarking trees, Australian farmers were able to greatly increase stock numbers. Twenty million sheep in 1860 grew to more than 100 million just 30 years later (and peaked at 180 million in 1970).

No one can say how much fencing, let alone barbed wire fencing, exists in Australia. The last fencing census in the 1890s recorded 1.6 million kilometres of fences in New South Wales alone. According to Pickard, today 'tens of millions of kilometres of fences subdivide the landscape,' most of it barbed. In a national survey in which he recorded fence details at 3642 sites, Pickard found that 78 per cent of fences had barbed wire, and 65 per cent had barb as the top strand.

These days, much of the fencing, about 50,000 km a year, is being erected in the name of nature conservation, to keep stock away from planted trees, remnant

Additional Documentation Attachment to Comment 2-F1
Attachment I-8

vegetation, wetlands and rivers. And, fencing is not only rural—there are also barbs in the 'burbs, as the favoured method of security fencing.

Victims of barb

No one can say how many wildlife victims barbed wire claims. Most fences are not regularly checked by humans, and the thousands of animals rescued from barbs each year would represent a miniscule proportion of those caught. Predators and scavengers probably pick off most of the bodies within a day or two.

The sheer extent of barbed wire suggests a large toll—an ever-so-tentative guesstimate is 100,000 to 1 million a year.

Some bats and gliders are particularly vulnerable to barbed wire. On the Atherton Tablelands alone, 100 to 400 flying-foxes are rescued from barbs each year. In Western Australia, the loss of Ghost Bats to barbed wire fences is considered a conservation threat. And barbed wire is a significant cause of mortality for threatened Mahogany, Yellow-bellied and Squirrel Gliders.

Barbs seem to be of less conservation significance for birds. Nevertheless, poorly considered fencing around wetlands is considered an emerging threat for Brolgas and Sarus Cranes in some places (see Box) and barb entanglements (and fences in general) may be of concern with rare owls.

In the absence of data suggesting conservation threat, it is fair to say that for most birds barbed wire entanglements are mainly of welfare concern.

Which birds are the main victims and how do they become snagged?

Frogmouths, owls and raptors—perhaps swooping at or pursuing prey and failing to see a fence. Tawny Frogmouths and Southern Boobooks dominate rescue lists, but this could be due in part to their relatively greater prevalence in human-populated areas. Chris Lloyd, ornithologist with the New South Wales Wildlife Information and Rescue Service (WIRES), suggests that based on entanglement rates of these more common night birds, it would not be surprising if fences were a threat for some rarer owl species. In New South Wales, WIRES rescues dozens of raptors a year from barbs.

Emus—perhaps pursued by a dog and throwing themselves at a fence to get across, or even just quietly trying to get through and becoming entangled.

Large waterbirds, such as Brolgas and Black-necked Storks—with long legs dangling during take-off and landing, and struggling to get airborne, they may not

quite clear a fence close to a wetland (see Box).

Other birds, of any sort really—with the sun in their eyes, or tired or being pursued, or at night, failing to see or clear a fence, or being unaware of a newly constructed fence. A recent story in the *Cairns Post* reported 50 Metallic Starlings ensnared by a construction site fence cutting across the flight path to their roost tree. One birder told me of rescuing an entangled Australian Magpie and a Pied Butcherbird on different occasions: each had been trailing string for their nest, which had been caught on a barb.

Lloyd notes that, barbed or not, fences are hazardous for birds such as frogmouths, owls and raptors, which may hit them at speed and break bones.

Snagging circumstances

In order to prioritise efforts to reduce the barb toll, it's important to understand the circumstances in which snagging most often occurs. Current information is that most wildlife is caught on the top strands of a fence. So, replacing the top couple of strands with plain wire would save many.

There are hotspots of entanglement—around wetlands, creeks and food trees and along ridgelines, for example. So, removing, moving or replacing barbed wire in fences in these localities is a priority.

Most entanglements occur at night, suggesting that many animals become snagged because they fail to see a fence. So, there may be strategies to make fences more visible, and various landholders are trying out used electric fence tape, old CDs, bunting, aluminium pie shells and aluminium tags to make fences more visible.

Other factors less amenable to management include inexperience (young animals are more susceptible), weather (particularly windy weather) and hard times (hungry animals are more prone to mistakes).

Fencing alternatives

The welcome news for wildlife is that barbed wire is no longer the only effective and cost-effective way to fence.

According to the farm fencing manual *Wires and Pliers*, highly tensioned plain wire fences are effective and can withstand high loads, except perhaps 'in the case of a direct collision … by a fast-moving heavy beast.' 'Plain wire works in pastoral areas' is the blunt title of the contribution to the manual by the Western Australian Department of Agriculture.

Central Queensland fencing contractor Ren Lanyon says highly tensioned plain wire is good for almost all

Rescuing wildlife entanglement

Barbed wire is a heartbreaking problem for wildlife carers. By the time an animal is found and a rescuer called, it has often been snagged for hours, sometimes days, exposed to the elements and twisting and flailing around. Typically, at least half of the animals rescued have to be euthanased because the damage is too great. The fortunate few often have to be in care for months while tissues heal.

Senior vet of the Australian Wildlife Hospital Dr Jon Hanger has the following advice for people who find entangled wildlife. Try to keep the animal calm and shaded by draping a light towel over it, and call a wildlife rescue organisation. However, if you are in a remote area or the animal is thrashing about and is likely to increase the extent of injury before help can arrive, you could try to release it from the fence. Restrain the animal with a towel, and cut the wire either side of the snagged flesh. However, *be very careful* when cutting a fence to avoid injury from wire that whips back upon release from tension.

Do not attempt to untwist the barbs from the flesh as that is likely to do more damage. Put the animal in a covered box and seek veterinary or wildlife care help.

All entangled animals should be examined under anaesthesia by a vet. Many injuries are not visible and will become apparent over time.

NOTE: Health authorities warn that people should not handle bats, because of the threat of lyssavirus infection, which is fatal for humans. If you are scratched or bitten by a bat you will need to be vaccinated.

Also note that cutting fences without permission of the landholder may be illegal.

The injuries sustained by a newly fledged Black-necked Stork when it became snagged on a barbed fence at Woodford Island, New South Wales, in 2003. It was taken to a veterinary hospital: the vet was hopeful, but the stork died. Photo by **Greg P. Clancy**

AR060469

situations and cheaper than barb because it uses thinner wire, and fewer fence posts are needed, thus reducing the use of timber. It also has the benefit that is does not scar the hides of cattle, which would add value to Australia's cattle industry.

The major barrier to fencing reform seems to be habit. Lanyon says he has been trying to persuade graziers to use plain wire for a couple of decades, but there is reluctance to risk a new approach when barbed wire has worked for generations.

Changing a fencing culture

Internationally, there are moves away from barbed wire. In Europe many local and county governments have already banned barbed wire fencing for its impact on wildlife, and there are moves within the European Union animal welfare sector to have it banned Europe-wide.

In the US, some environment groups are working to remove or replace barbed wire fencing due to its impacts on birds and grazing animals. In addition, in the tradition of the fence-breachers of the late 1800s, some 'eco-guerillas' have been taking to barbed wire fences on public lands with cutters.

In Australia, the Wildlife Friendly Fencing project (see www.wildlifefriendlyfencing.com), with funding from the Threatened Species Network (WWF), is working with landholders to identify and promote alternative approaches to fencing. The project is coordinated by the Tolga Bat Hospital on the Atherton Tablelands, and supported by wildlife and welfare groups.

One of the project goals is to gather better information about fencing impacts. If you have seen entangled wildlife (dead or alive), please record it on a form accessible on the fencing website. The information will go into a database to analyse the extent and patterns of entanglements.

Another goal is to support landholder champions of wildlife-friendly fencing by assisting with fencing materials and reporting on approaches being tried. For example, project coordinator Jenny Maclean reports that one landholder in a bat entanglement hotspot is topping an existing barbed wire fence with used white electric fence tape to make it more visible. Another has replaced the top strand of barb with a glow-in-the-dark nylon fencing material. Another is moving a fence from the top of a ridge to a safer location.

The wildlife-friendly fencing website also hosts a draft action plan on barbed wire, which summarises existing information on barbed wire problems and options for mitigation and prevention. Your feedback on this plan is welcomed.

Fences are one of the prominent marks of human civilisation—you can be way out whoop-whoop in Australia, but the human stamp on the landscape is there at least in the form of a fence. When asked what he thought about British civilisation, Gandhi was said to have remarked that it would be a good idea. Taking our cue from Gandhi, it would be a very good idea to adopt a more civilised fencing culture that embodies the best of humanity—our capacity for empathy and concern for other creatures—and move on from the barbarity of barbs.

Cranes and fences

Ironically, one of the emerging threats for Sarus Cranes and Brolgas in northern Australia is conservation-motivated fencing of wetlands that fails to consider how these birds use wetlands. The Australian Crane Network (see http://ozcranes.net) is urging closer consideration of fencing methods.

Cranes need plenty of room around wetlands for take-off, landing and displaying. With long legs dangling for landing and take-off and wingspans over two metres, they are vulnerable to entanglement, particularly in barbed wire fences.

Fences too close to water prevent their run-up to flight and other land-based behaviours. Fences may also prevent young from leaving a wetland until they fledge (at about 14 weeks age), and so increase risks of predation and stranding or drowning if the wetland is flooded, as well as the effort needed by parents to feed their trapped chick.

Fences that totally exclude grazing sometimes result in wetlands becoming over-grown with weeds or shrubs and thereby lost as habitat for cranes.

OzCranes Network recommends the following fencing approaches:

- **use safer materials (not barbed wire)**
- **mark the top wire near flight paths (to alert birds to its presence)**
- **fence a larger area (which could include scattered trees) well back from water**
- **install gates for management access**
- **control rank growth as part of scheduled property management (grazing, fire, chemical, or mechanical).**

SUMMARY

Desert Quartzite, LLC has requested a right-of-way grant from the Bureau of Land Management (BLM) to construct and operate a new solar photovoltaic energy generating facility in unincorporated Riverside, California near the interstate boundary of California and Arizona, just east of Blythe in Riverside County, California (Case File Number CACA-49397). The solar facility and associated generation interconnection line are collectively referred to in this report as the Desert Quartzite Solar Project (Project). The Project site is located outside the boundaries of any Area of Critical Environmental Concern, Desert Wildlife Management Area, Wilderness Area, or designated Critical Habitat Unit.

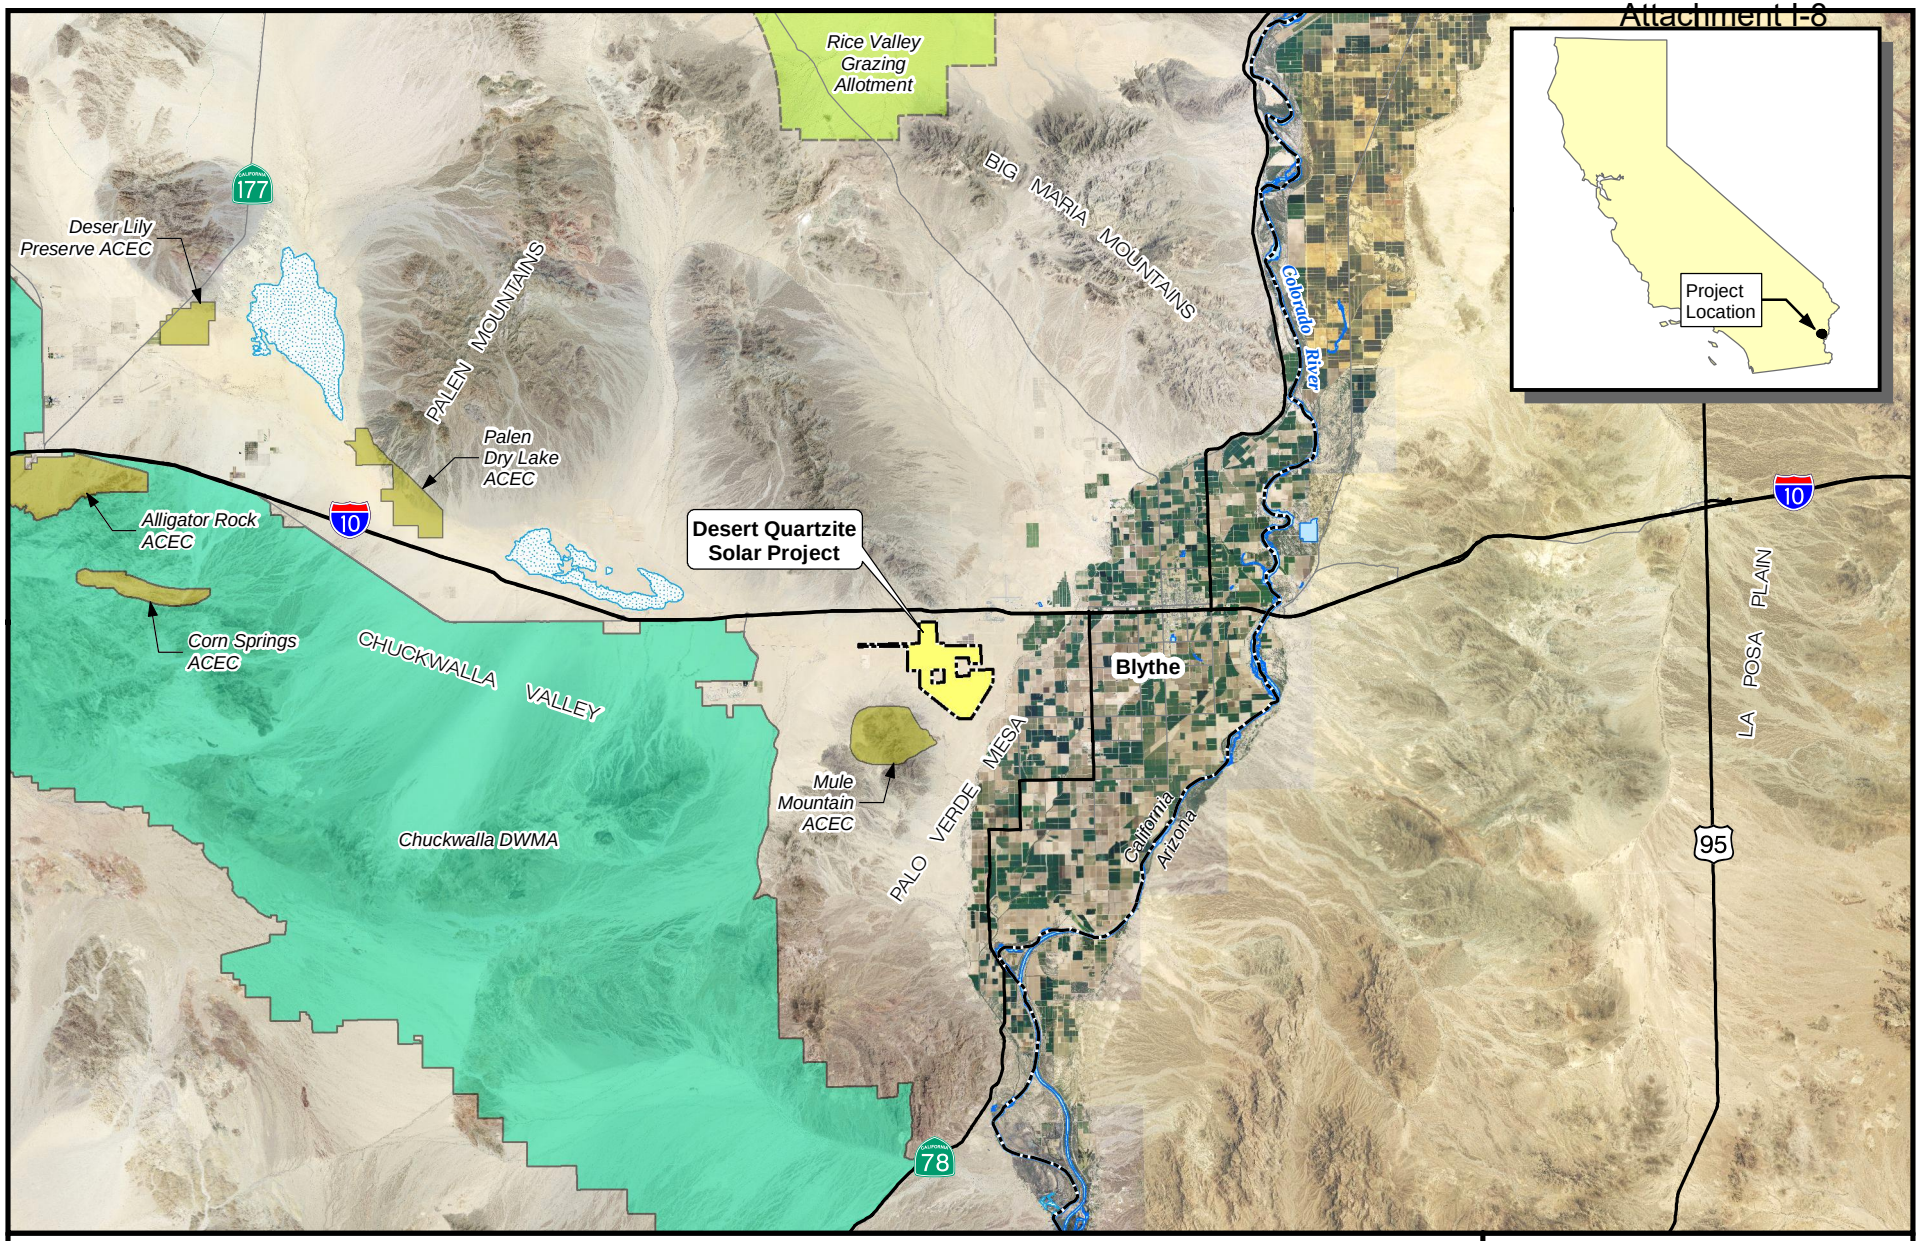
This report provides a comprehensive description of methods and results of biological resource surveys and investigations conducted in fall of 2012 and spring of 2013 within the Study Area (See Section 1.4). The purpose of the surveys was to provide information supporting consultation between BLM, United States Fish and Wildlife Service (USFWS), and California Department of Fish and Wildlife (CDFW) with respect to the California and Federal Endangered Species Acts, National Environmental Policy Act (NEPA) and the California Environmental Quality Act (CEQA). Survey standards and recommended protection measures described in this report are consistent with the Best Management Practices and Guidance Manual: Desert Renewable Energy Projects (Renewable Energy Action Team 2010).

Focused botanical surveys resulted in the documentation of six special status (California Native Plant Society list status) plant species within the Study Area including Harwood's milkvetch (*Astragulus insularis var. harwoodii*), Abram's spurge (*Chamaesyce abramsiana*), ribbed cryptantha (*Cryptantha costata*), Harwood's eriastrum (*Eriastrum harwoodii*), Utah vine milkweed (*Funastrum utahense*) and desert unicorn-plant (*Proboscidea althaeifolia*). More than 124 species of plants were identified during the surveys. Federal or state listed (endangered or threatened) plant species were not observed.

Full-coverage surveys for desert tortoise (*Gopherus agassizii*), the only animal species listed as federal and state endangered with potential to occur on site, was conducted in 2013. Tortoise sign observed during survey consisted of six carcasses, all-greater than 4 years old and disarticulated, and one set of tortoise tracks. Live desert tortoise were not observed during surveys.

Numerous Mojave fringed-toed lizards (*Una scoparis*), which is a species of concern, were found while performing surveys in the western portion of project where soils consist of much finer sand. Other special status wildlife species observed or likely to occur within the Project site included loggerhead shrike (*Lanius ludovicianus*), burrowing owl (*Athene cunicularia*), LeConte's thrasher (*Toxostoma lecontei*), American badger (*Taxidea taxus*), desert kit fox (*Vulpes macrotis arsipus*), pallid bat (*Antrozous pallidus*), small-footed myotis (*Myotis ciliolabrum*), and Townsend's big-eared bat (*Plecotus townsendii*).

1.0 INTRODUCTION



1.1 PURPOSE

This Biological Resources Technical Report (BRTR) provides a comprehensive description of methods and results of biological resource surveys and investigations conducted to date within the Study Area (See Section 1.4) for the Desert Quartzite Solar Project (Project) as proposed by Desert Quartzite, LLC. The purpose of the surveys is to support consultations between Bureau of Land Management (BLM) and United States Fish and Wildlife Services (USFWS) under Section 7 of the Federal Endangered Species Act (FESA), and any necessary incidental take authorization from the California Department of Fish and Wildlife (CDFW) with respect to the California Endangered Species Act (CESA). The data contained within this report also provides information to promote compliance with requirements of the National Environmental Policy Act (NEPA) and the California Environmental Quality Act (CEQA). Survey standards and recommended protection measures described in this report are consistent with the Best Management Practices and Guidance Manual: Desert Renewable Energy Projects (Renewable Energy Action Team 2010).

1.2 SITE LOCATION

The Project site is located in unincorporated Riverside, California. It is situated south of Interstate 10 (I-10), approximately ten miles west of the City of Blythe, California (Figure 1). The Project site is located on the Ripley and Roosevelt Mine 7.5-Minute United States Geological Survey (USGS) topographic quadrangle. Elevation at the site ranges from approximately 320 to 475 feet above mean sea level (amsl). The Project is located on the Palo Verde Mesa within BLM land designated as Multiple-Use Class M (Moderate Use). The Project site is located outside the boundaries of any Area of Critical Environmental Concern (ACEC), Desert Wildlife Management Area (DWMA), BLM wilderness area, or USFWS designated critical habitat unit for desert tortoise. The Mule Mountains ACEC, which was established to manage prehistoric resources, is located less than one mile west of the Project site. The Chuckwalla DWMA for desert tortoise is located approximately twenty miles west and the current Herd Management Area (HMA) for burros is located approximately five miles south of the Project site. Please see Table 1 for additional adjacent land uses.

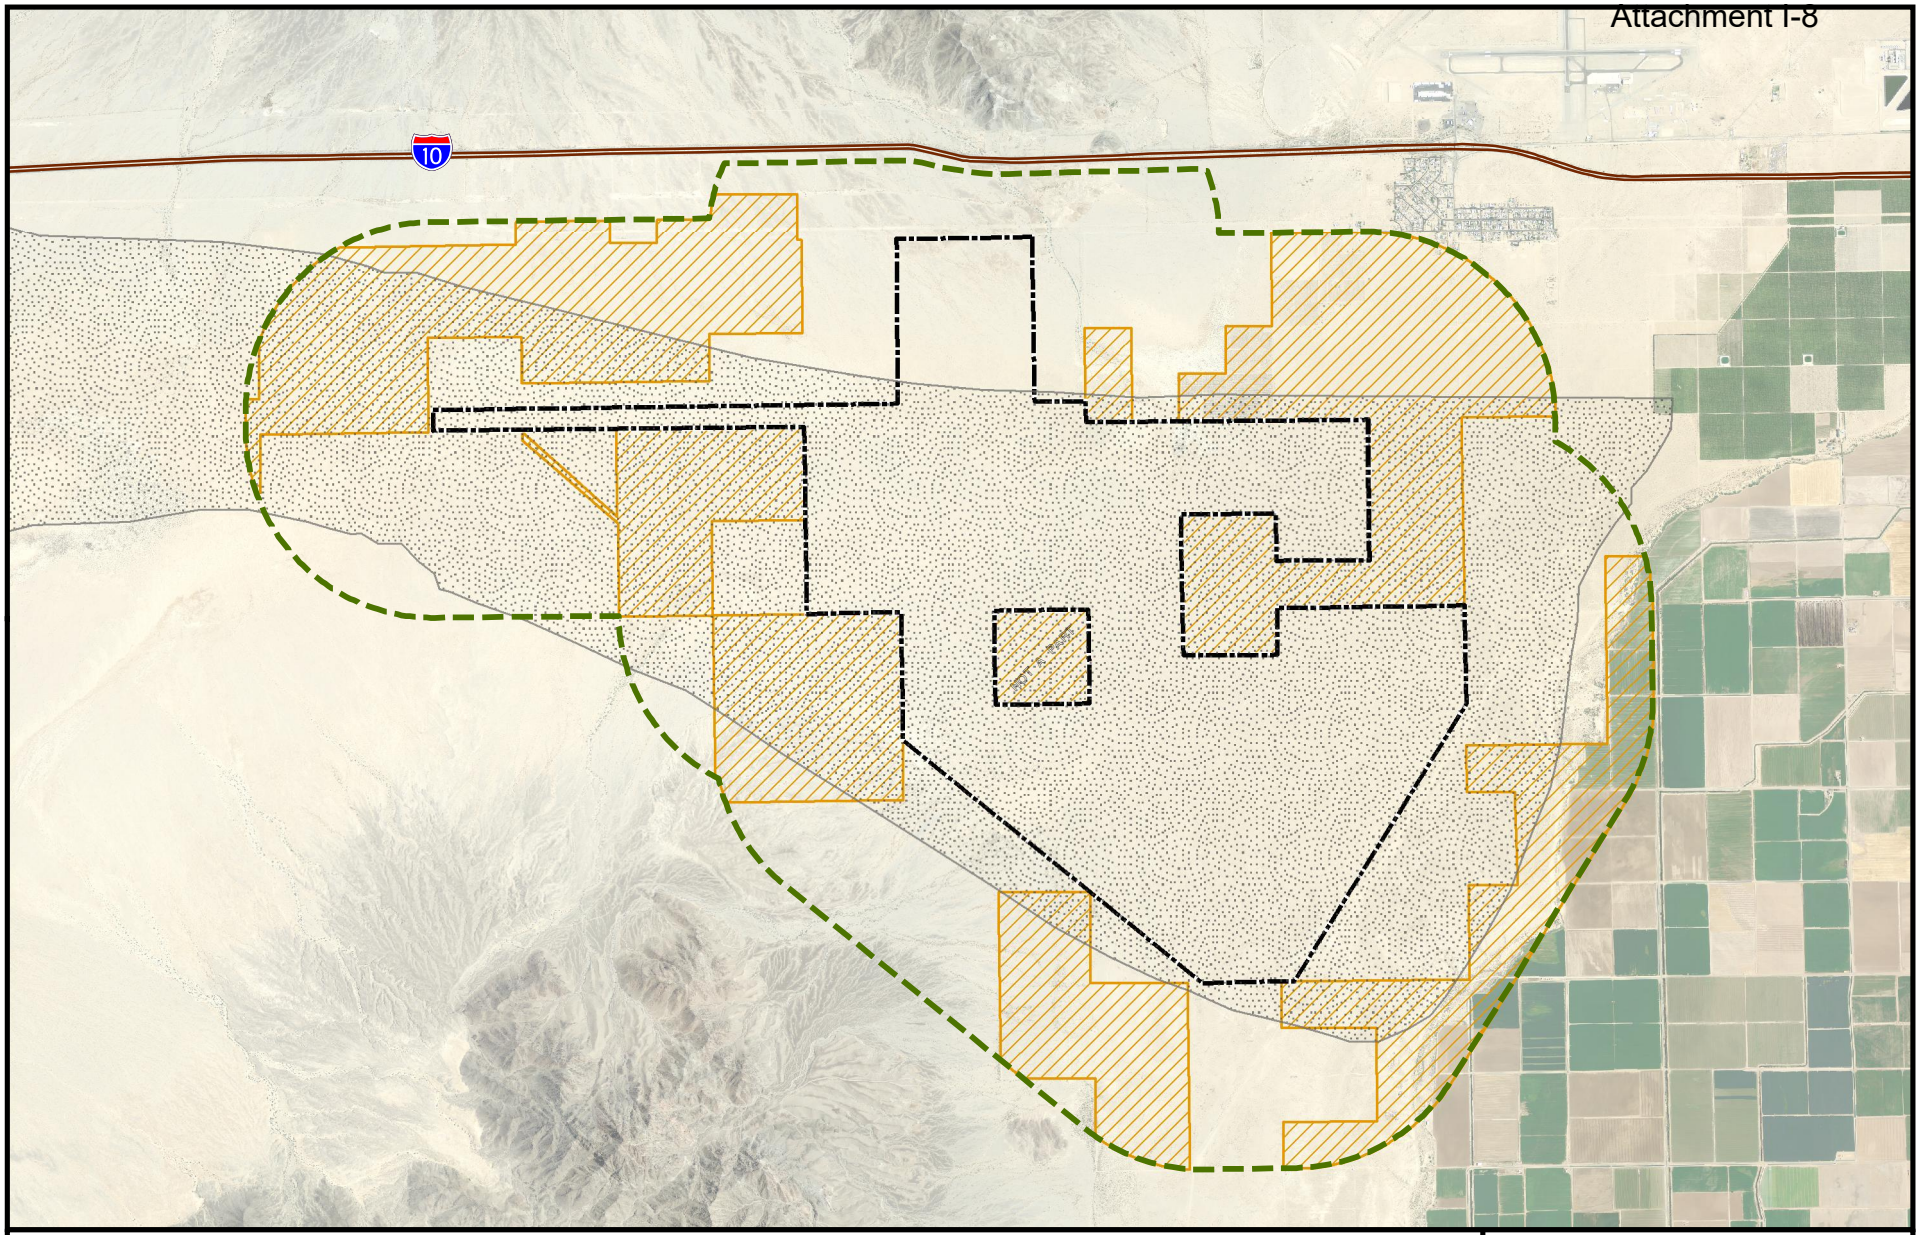
South	Southern extent of Palo Verde Mesa; Mule Mountains; BLM Limited MUC land with interspersed privately owned land
West	Southern California Edison's Colorado River Substation; Mule Mountains; BLM Moderate and Limited MUC land with interspersed privately owned land



1.3 SITE CHARACTERISTICS

Based on visual observations of surface soils, soils within the Project site appear to be dominated by gravely sands and sandy loams, and ranged in texture from very fine sand to gravel. Formal site soil data from the Natural Resources Conservation Service (NRCS) is not available in the northwest portion of the Project site. Desert pavement is present in the extreme northwest and southwest limits of the Project site. Human disturbances within the Project site include off-highway vehicle (OHV) activity, existing utility corridors (i.e., overhead power transmission lines and underground petroleum pipeline), residential trash dumping and access roads for both utilities and fallow agriculture sites.

1.4 STUDY AREA

For the purposes of this report, the Project site is the area that was described in the updated Application for Transportation and Utility Systems and Facilities on Federal Lands (SF 299). This updated version decreased the size of the Project site from 7,272 acres to the current 4,885 acres. The Project site includes the electrical generation interconnection (gen-tie) transmission line to the existing Southern California Edison's (SCE) Colorado River Substation. Generally, the Study Area is the combination of the Project site and a one-mile buffer around the Project site (Figure 2). Specific species survey protocols may require a buffer larger or smaller than the one established for this project (e.g., golden eagles and bats). This buffer area will allow for adjustments to access roads and or other project related activities outside of the current proposed location. Since the gen-tie line is included as part of the Project site, the Study Area buffer was also included around this area.

1.5 PROJECT SUMMARY

The Project, as proposed, is described in general terms below. Specific details of the Project description are included in other related documents including the Plan of Development (POD). The Project would include the solar facility (where the electrical power will be generated) and a 300-kilovolt (kV) transmission line (gen-tie Line). The solar facility would consist of several main components, all located within the Project security and permanent desert tortoise fencing:

- Main Generation Area – Photovoltaic (PV) arrays, combining switchgear, overhead lines, and access corridors;
- Operations and Maintenance (O&M) Facility;
- On-site substation; and
- Fencing and lighting.

The Project would interconnect with the regional transmission system via a 300-kV single-circuit gen-tie line that will be located on the western portion of the Project site and follow a 160-foot-wide transmission right of way (ROW) to the existing SCE's Colorado River Substation located approximately one mile west of the solar facility's western boundary. Construction of the Project would be completed in three basic phases: 1) pre-construction activities, 2) site preparation; and 3) construction and installation of the solar photovoltaic (PV) modules and electrical components, including the gen-tie line.

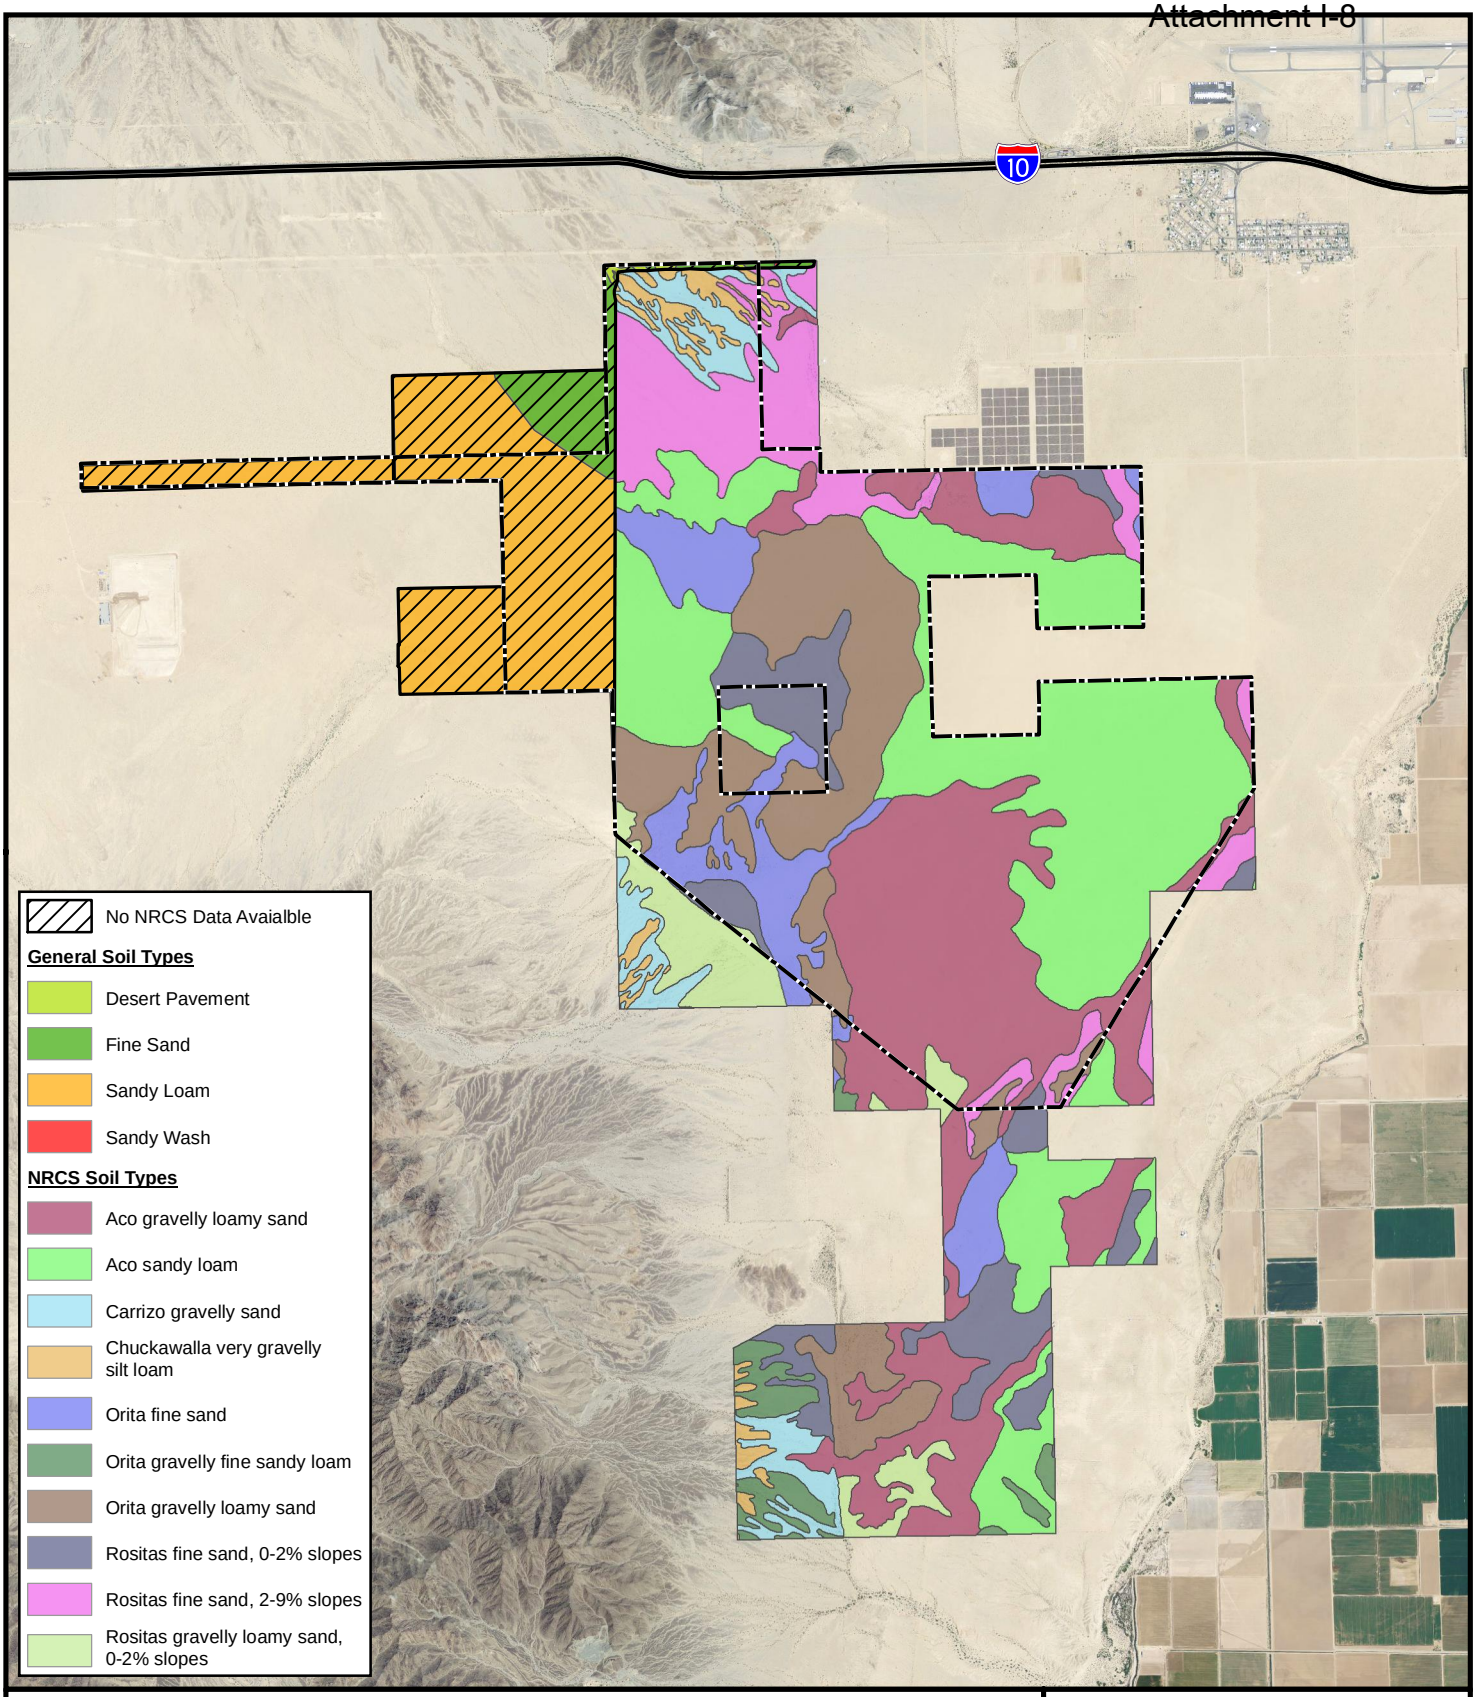
2.0 METHODS

2.1 SPECIAL STATUS SPECIES DEFINITION

For assessment purposes in this report, a special status species has been defined as a plant or wildlife species that meets one or more of the following criteria:

- Designated as either rare, threatened, or endangered by CDFW or the USFWS, and are protected under either CESA or FESA;
- Candidate species being considered or proposed for listing under these same Acts;
- Species of special consideration as referenced in the Northern and Eastern Colorado Coordinated Coordination Plan (NECO) and Final Environmental Impact Statement (FEIS) (Bureau of Land Management 2002) and Biological Opinion for the NECO Plan (United States Fish and Wildlife Service 2005);
- State Species of Special Concern as designated by CDFW;
- Considered endangered, threatened, or rare pursuant to CEQA Guidelines, Section 15380; or
- Considered listed under by California Native Plant Society (CNPS).

2.2 PRELIMINARY MAPPING



A large-scale aerial photograph of the Study Area was created and used to preliminarily map vegetation communities, soil substrates, and other areas of interest during the survey. Such areas included those that appeared to have unique plant assemblages or areas of interest under NECO including desert dry wash woodland habitat. The preliminary mapping effort allowed surveyors to focus on areas most likely to support special status species and habitats, while characterizing each type of vegetation community and soil substrate.

The 2008 mapping was for a project site approximately 7,272 acres. The current Project site is 4,885 acres. The southern portion of the original site boundary has been removed.

2.3 SOILS

Soils within the Project site are dominated by gravely sands and sandy loams, and ranged from very fine sand to gravel (Figure 3). The Natural Resources Conservation Service (NRCS) Web Survey contained data for the majority of the Project site. NCRS data is not available for the northwest portion of the Project site.

Figure 3

Soil Types

2.4 RAINFALL ANALYSIS

Measurements of total and average precipitation during winter periods (October through March) are important in determining the efficacy of both desert tortoise and special status plant surveys. Per the USFWS desert tortoise protocol, data was obtained from the Western Regional Climate Center (2013). The Blythe CAA Airport, California weather station (elevation 390 feet (ft) above mean sea level (amsl), approximately three miles north of the Project site and is the most proximate station. The rainfall data that was obtained and utilized for the surveys can be located in Appendix A.

2.5 STUDY PLAN

Several species of flora and fauna known to occur on or near the Project are accorded "special-status" by federal and state agencies because of their recognized rarity or potential vulnerability to extinction. These species typically have a limited geographic range and/or limited habitat and are collectively referred to as "special-status" species. Additional species protected by other regulations within the region were added to the overall species survey list and are referred to in this document as the target species. According to the NECO Plan (BLM and CDFW 2002) surveys must be completed where a project intersects the species' ranges as represented and mapped within the plan. Since, the Project site is within NECO, species covered in this document but not necessarily recognized as a "special status" species were added to the target species list. Managed big game species and burros (protected by the Wild Free-Roaming Horse and Burro Act) were also included as target species. Desert kit fox (*Vulpes macrotis*) being a protected furbearer, per California Department of Fish and Game Code (California Department of Fish and Wildlife 2013a), was also included as a target animal species.

Comprehensive biological resource surveys designed to meet all applicable USFWS, BLM, and CDFW requirements were performed in the fall of 2012 and in spring 2013. Surveys for biological resources were conducted within the Project site and up to a one-mile buffer around the proposed disturbance area. The entire 4,855-acre survey area with the buffer area will collectively be called the Study Area within this BRTR. (The Project Site Boundary and the Site Boundary Buffer depicted on Figure 2 make up the Study Area.) Any modifications to this Study Area due to specific protocol or guideline changes will be discussed for the species for which they occur. During the fall of 2012 and spring of 2013, a full focused rare plant survey was performed on the Project site. In addition to the focused rare plant surveys, project biologists completed the following surveys within the Study Area: vegetation mapping, general wildlife surveys, protocol desert tortoise surveys, protocol western burrowing owl surveys and avian point count and migration surveys. Other studies performed on site were the spadefoot and elf owl habitat assessments and the protocol golden eagle surveys. The section below details the specific methodologies and protocols utilized for the Project's biological resources surveys within the Study Area.

"Established protocols," which in this case is a species listed as threatened or endangered by the federal or state government, are guidelines promulgated by USFWS or CDFW, respectively. In an effort to gain consensus regarding the survey methodologies to be employed, the Project team initiated discussions with USFWS, BLM, and CDFW, (hereafter collectively referred to as "the agencies"). The protocols were submitted for review to the agencies and modified slightly based on input received from the agencies.

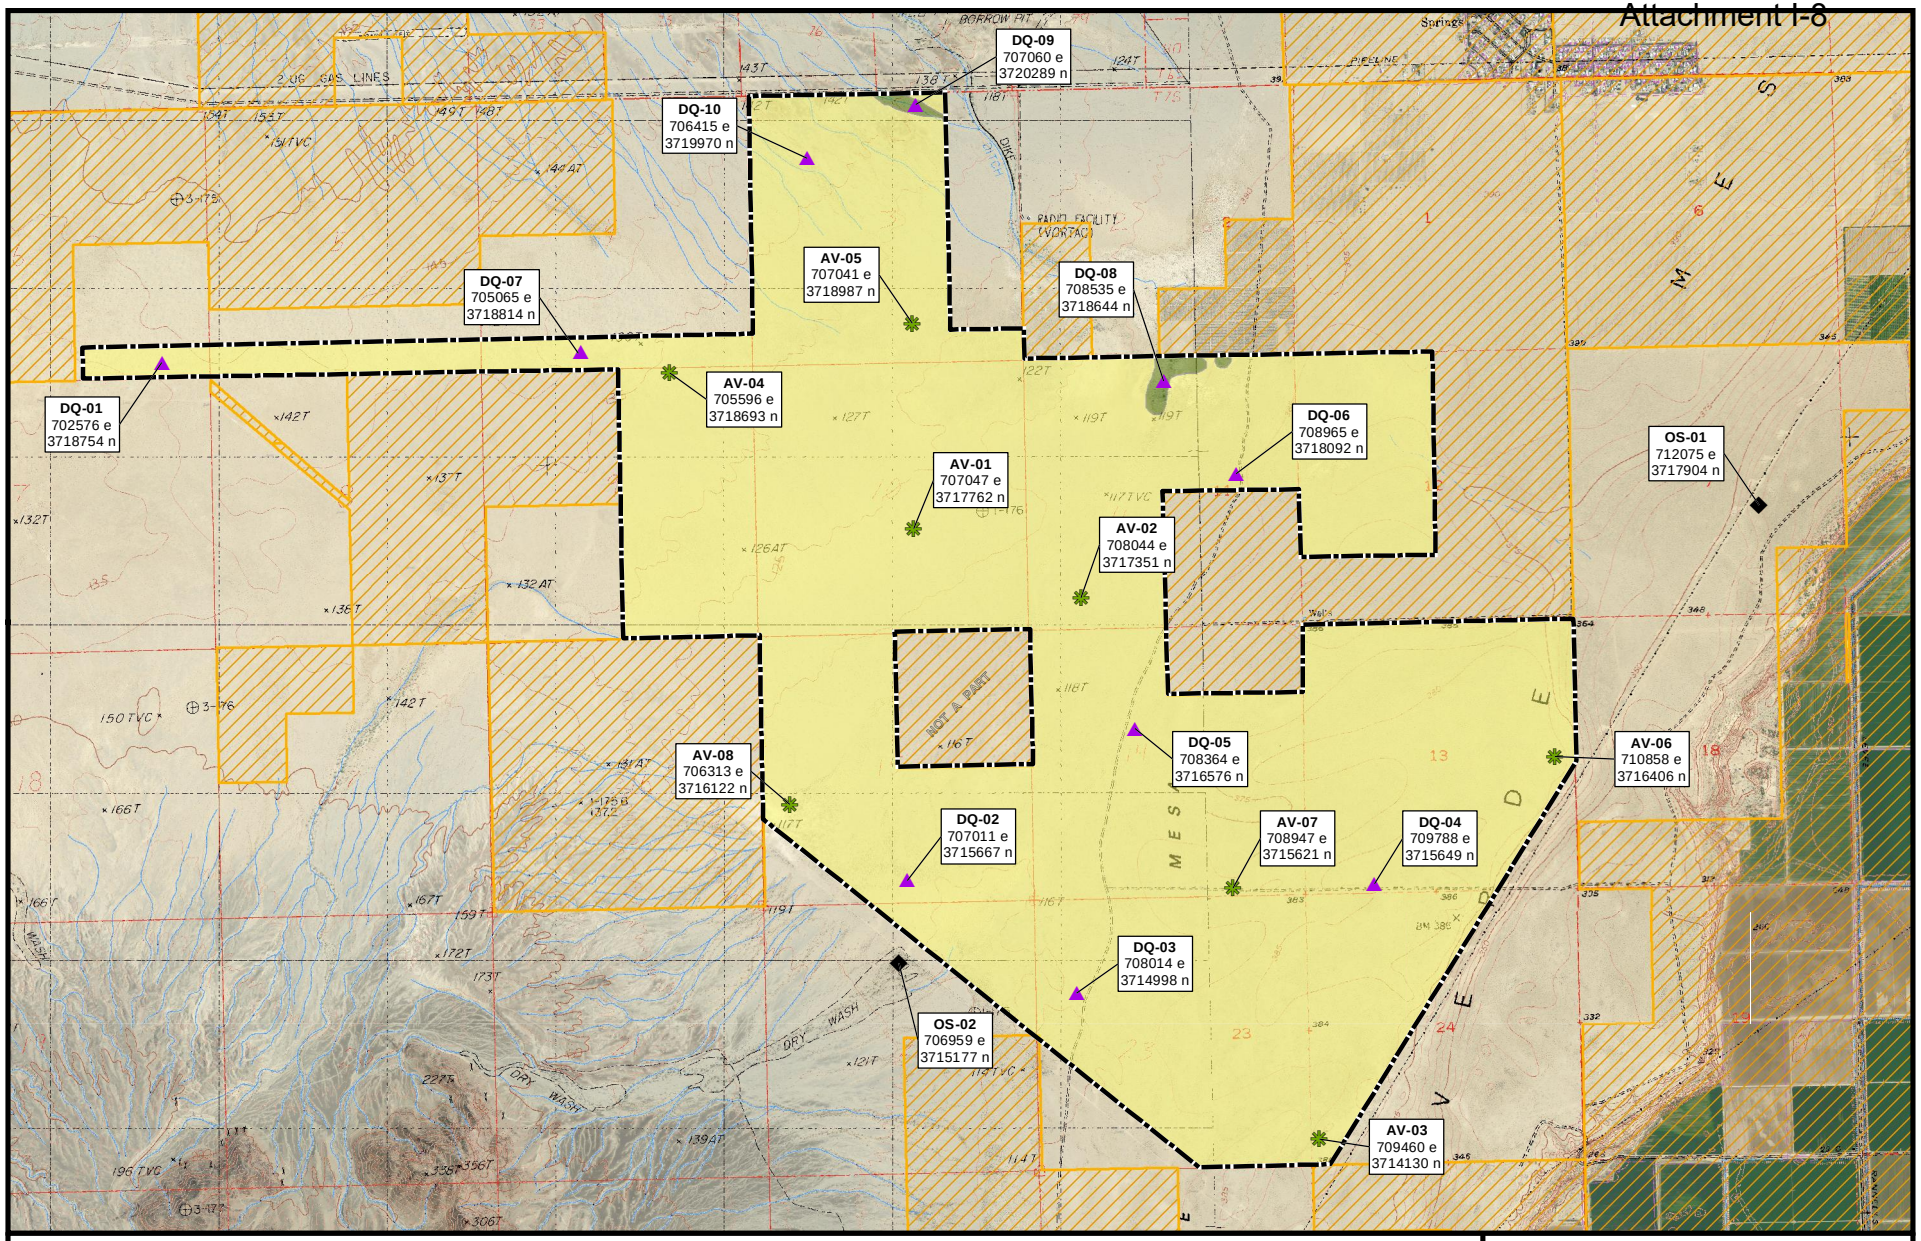
The species detected in the study area are listed in Appendix B and the special status target plant list is provided in Appendix C.

2.6 BASELINE SAMPLING

Twelve primary sampling stations (vegetation, avian, reptile, and small mammal sampling), were established (Figure 4) to provide information of species composition and provide baseline quantitative data for future monitoring associated with the Project. Ten sampling stations were established within the Project site and two offsite as controls. Sampling stations were randomly generated to obtain a sufficient representation of the area. Each sampling location represented the center or corner point of larger linear transects or grids depending on the specific survey methodology as described in the following sections.

2.7 BOTANICAL STUDY

Surveys were performed to determine the presence and distribution of special status plant species and estimates of succulent species (cacti and yucca) within the Study Area. Vegetation sampling was also performed under the baseline survey effort as described in this section.



2.7.1 Special Status Plant Species

Special status plant species have been identified as potentially occurring in the vicinity of the Project site. The site specific special status target plant species list (Appendix C) was generated by searching multiple databases and reference sources for occurrence records, including:

- California Natural Diversity Database (California Department of Fish and Wildlife 2012)
- Northern and Eastern Colorado Desert Coordinated Management Plan (Bureau of Land Management 2002),
- Consortium of California Herbaria, 10,000 meter search centered at project site (Consortium of California Herbaria 2012); and
- BLM Palm Springs South Coast Field Office Sensitive Plant List: Desert Species (Bureau of Land Management 2012b).

In addition, records were reviewed from the greater southern California desert region.

DESERT QUARTZITE, LLC

Figure 4

Baseline Points

AR060493

A list of special status target plants, as defined in Section 2.5, was assembled from a 12-quad CNDDB search centered on Ripley and Roosevelt Mine quads, as well as California Consortium of Herbaria records queried within a 10,000 meter (m) radius of the site. Additional information (especially on probability of occurrence and habitat) was gathered from several biologists with extensive experience in the surrounding areas. Rarity ranks conform to the CDFW CNDDB plant listing of April 2013 (California Department of Fish and Wildlife 2013).

Surveys were developed and conducted to maximize the likelihood of locating special status plant species or special status natural communities within the Project site. The primary objective was to identify all plant species to the taxonomic level (i.e., species, subspecies, or variety) necessary to determine rarity status.

Rare Plant Surveys were designed and timed to conform to protocols detailed in BLM and CDFW protocols; BLM: Survey Protocols Required for NEPA/ESA Compliance for BLM Special Status Plant Species (BLM 2009) and CDFW: Protocols for Surveying and Evaluating Impacts to Special Status Native Plant Populations and Natural Communities (CDFW 2009). In summary, these protocols emphasize these major methods:

- Timing: Surveys should be conducted during the optimal season for positive identification of all target plant species, as well as justifiable on-site conditions for finding plants (adequate seasonal rainfall).
- Survey Intensity: Site coverage and surveyor spacing should be adequate for seeing and recording all potential rare plant species.
- Surveyor Qualifications: Surveyors should have experience identifying California desert rare plants, particularly Colorado Desert flora, be trained on the specific target plants through orientation meetings, specimen examples, and reference population checks prior to performing surveys on site.

Two formal Rare Plant Surveys were conducted across the Study Area detailed as follows:

- Fall 2012 (September 11 - 19) surveys were conducted after significant summer monsoon rainfall germinated abundant annuals and timing was good to observe and identify all potentially occurring fall-blooming target plants. Full coverage at 10 m spacing occurred across approximately 50 percent of the site (on loose sandy-gravelly soil in creosote bush scrub), and 20 m spacing was done on the remaining dry sandy areas where there was not significant annual germination.
- Spring 2013 (March 18 - 30) surveys were also conducted. Localized winter rainfall was enough to germinate copious annual blooms, and the timing was excellent for observing

and identifying all potentially occurring target plants. Full coverage transects were performed at 10 m spacing across the entire Study Area.

All data was recorded in triplicate form: paper data sheets, Global Positioning System (GPS) waypoints, and Pendragon handheld data collection forms. Data was proofed by Ironwood staff and periodically posted for review on Ironwood's Egnyte website.

In addition to Rare Plant Surveys, botanists also compiled and surveyed for a general Floristic Plant List with many voucher specimens, mapped vegetation communities, tracked weed infestations, and counted cacti.

In addition to Rare Plant Surveys, botanists also compiled and surveyed for a general Floristic Plant List with many voucher specimens, mapped vegetation communities, tracked weed infestations, and counted cacti.

2.7.2 Cacti and Yucca

Systematic sampling of succulents (cacti and yucca) was conducted during the fall 2012 plant surveys by botanists experienced with Colorado Desert flora. The purpose of this sampling effort was to estimate the number of individual cacti and yucca present. All species of cactus were documented and cumulative counts of the number of individual cacti were recorded. Yuccas were not observed on site.

2.7.3 Desert Dry Wash Woodland and Vegetation Communities

The science of vegetation classification is undergoing continued revision, with new nomenclature for previously described "vegetation communities." For the purposes of this report NECO common names (Bureau of Land Management 2002), with the latest nomenclature from **A Manual of California Vegetation, Second Edition** (Sawyer et al, 2009), and corresponding "Holland types" nomenclature (Holland 1986) will be used for each of these communities described below.

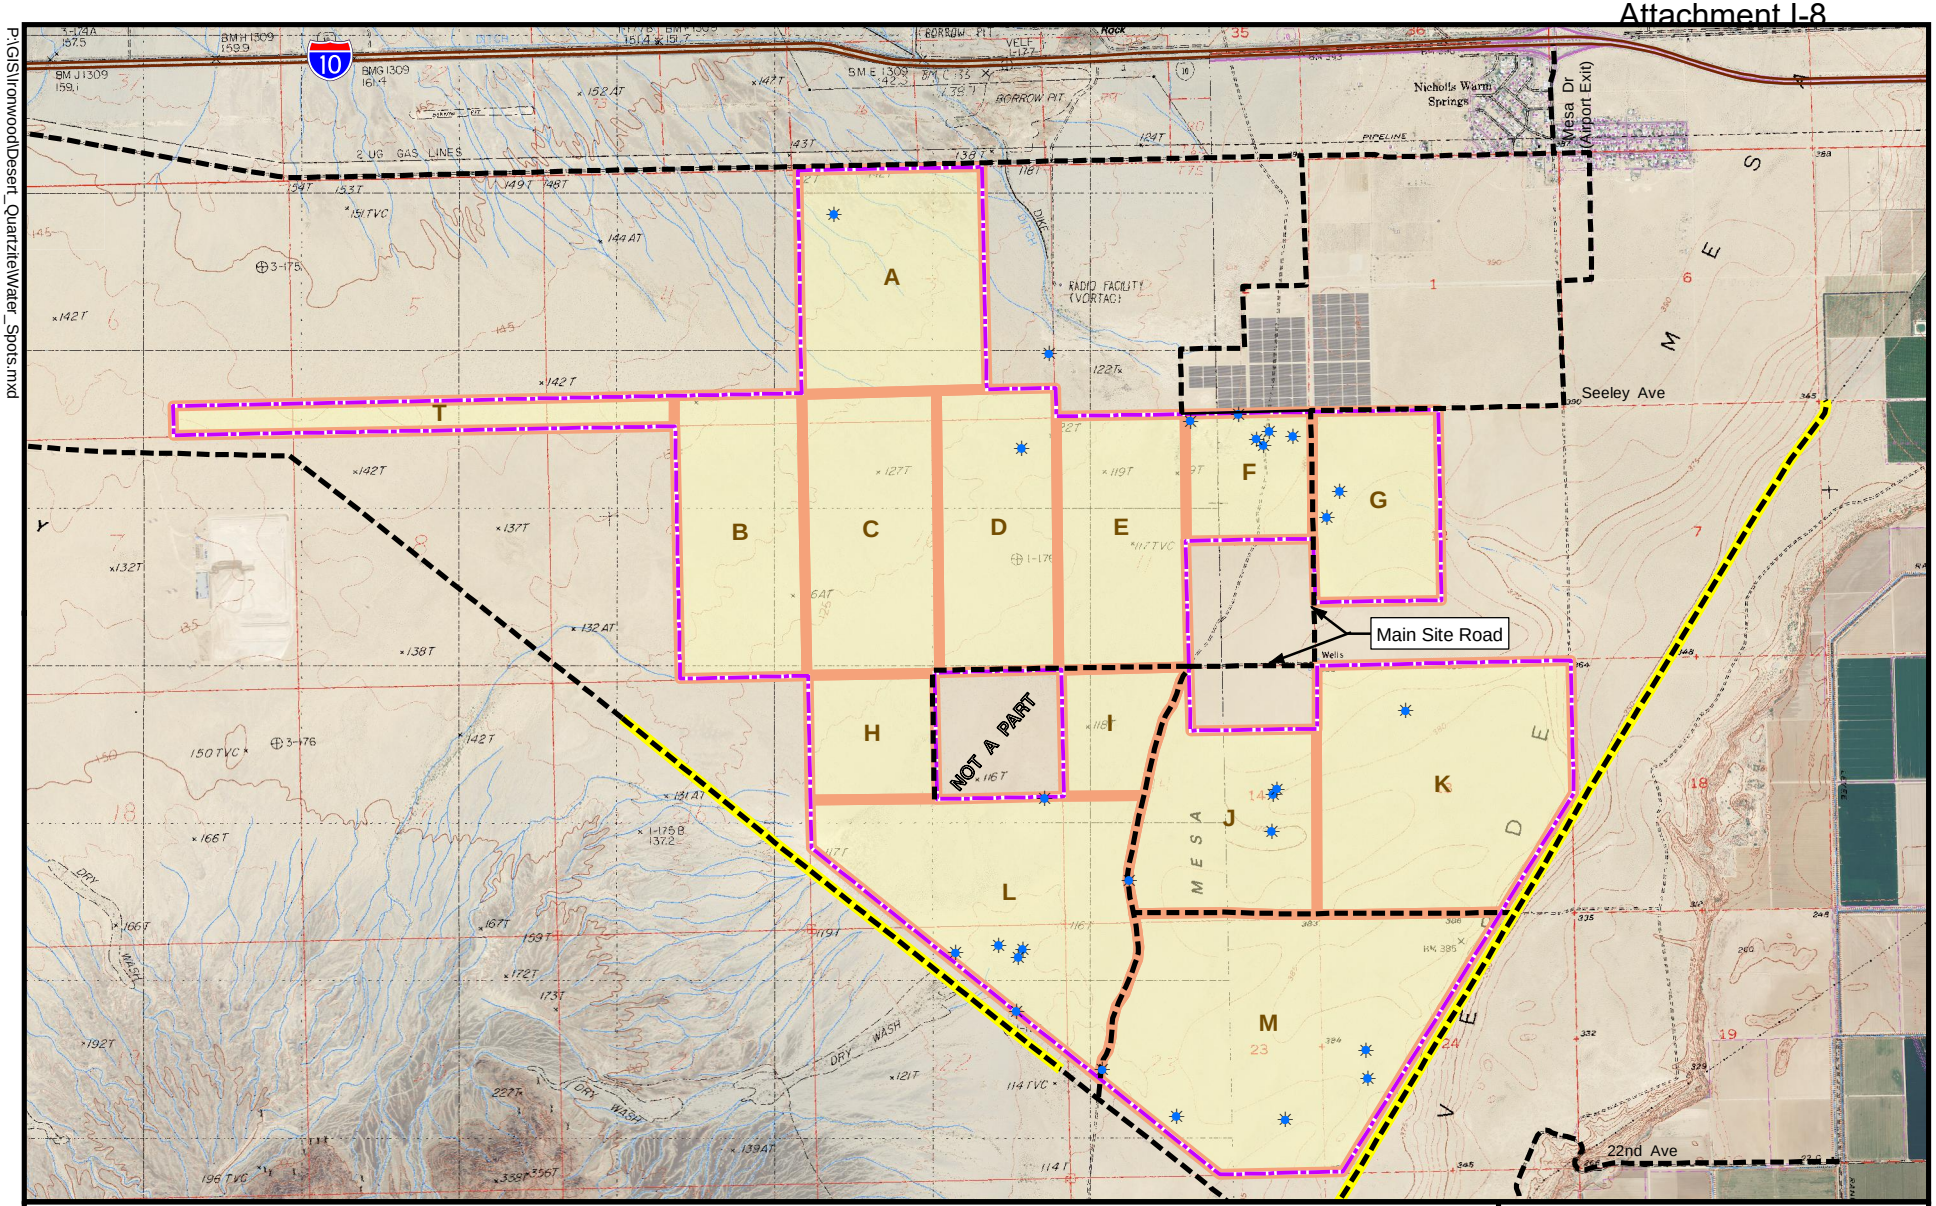
2.7.4 Non-Native and Invasive Species

Non-native and invasive species were documented during both the fall 2012 and spring 2013 plant survey season. During the fall season survey, the surveyors identified two invasive and two weedy non-native plants on the Project site. Due to the fact the species were found as dried up stems, the general location of these weeds were noted, but not located with a GPS or recorded. During the spring season, surveyors performed a detailed survey account of non-native and invasive plants on the Project site. The purpose of this sampling effort was to estimate the number of non-native and invasive species that were present on the site. All non-native and invasive species were documented and cumulative counts of the number of individual species were recorded.

2.8 AMPHIBIANS

There is one amphibian with the potential to be found on the project site, Couch's spadefoot (*Scaphiopus couchii*). There were 27 different points in the Study Area identified as having standing water at some time from 2008 until 2012 (Figure 5). Two locations were identified as likely to support Couch's spadefoot in the event of rains, due to the fact they were the most extant areas for having held water and exhibited a strong component of dry desert wash woodland plant species. One area was southeast of the existing solar facility and the second was south of the Project site in the Study Area buffer zone. Using this information, the surveyors monitored the areas during the monsoon season, summer of 2013, both to determine how long water was standing in these locations and to potentially identify if individuals were present.

2.9 REPTILES



2.9.1 Desert Tortoise Focused Surveys

Full-coverage protocol desert tortoise (*Gopherus agassizii*) surveys were conducted in the spring of 2013 (March 25 –April 15, 2013) according to the most current USFWS issued survey protocols (United States Fish and Wildlife Service 2010a). The protocols also provide methods to estimate the abundance of tortoises occurring within the Study Area. These desert tortoise surveys employed belt transects approximately 10 meters (33 feet) wide in order to provide 100 percent (full) coverage of the entire Study Area.

The survey crews consisted of highly experienced desert tortoise surveyors and field technicians of varying experience who attended field and training sessions prior to conducting surveys. The desert tortoise surveyors were divided into crews of approximately 3-4 people, with one or two highly experienced desert tortoise surveyors on each crew. Each of these crews typically surveyed approximately one square-mile section until the entire surveyed portion of the Study Area was covered.

All tortoise sign [e.g., live tortoises (all age classes), shell/bone/scutes, scats, burrows/pallets, tracks, egg shell fragments, and courtship rings] were recorded (Table 2). The location of tortoise sign was recorded on a Garmin GPS unit (GPS 72, 76, or 60CSx) using a unique identification code. In addition to recording sign with the GPS unit, standardized paper datasheets were completed. Data was entered from these datasheets into a Microsoft Access database, during post processing.

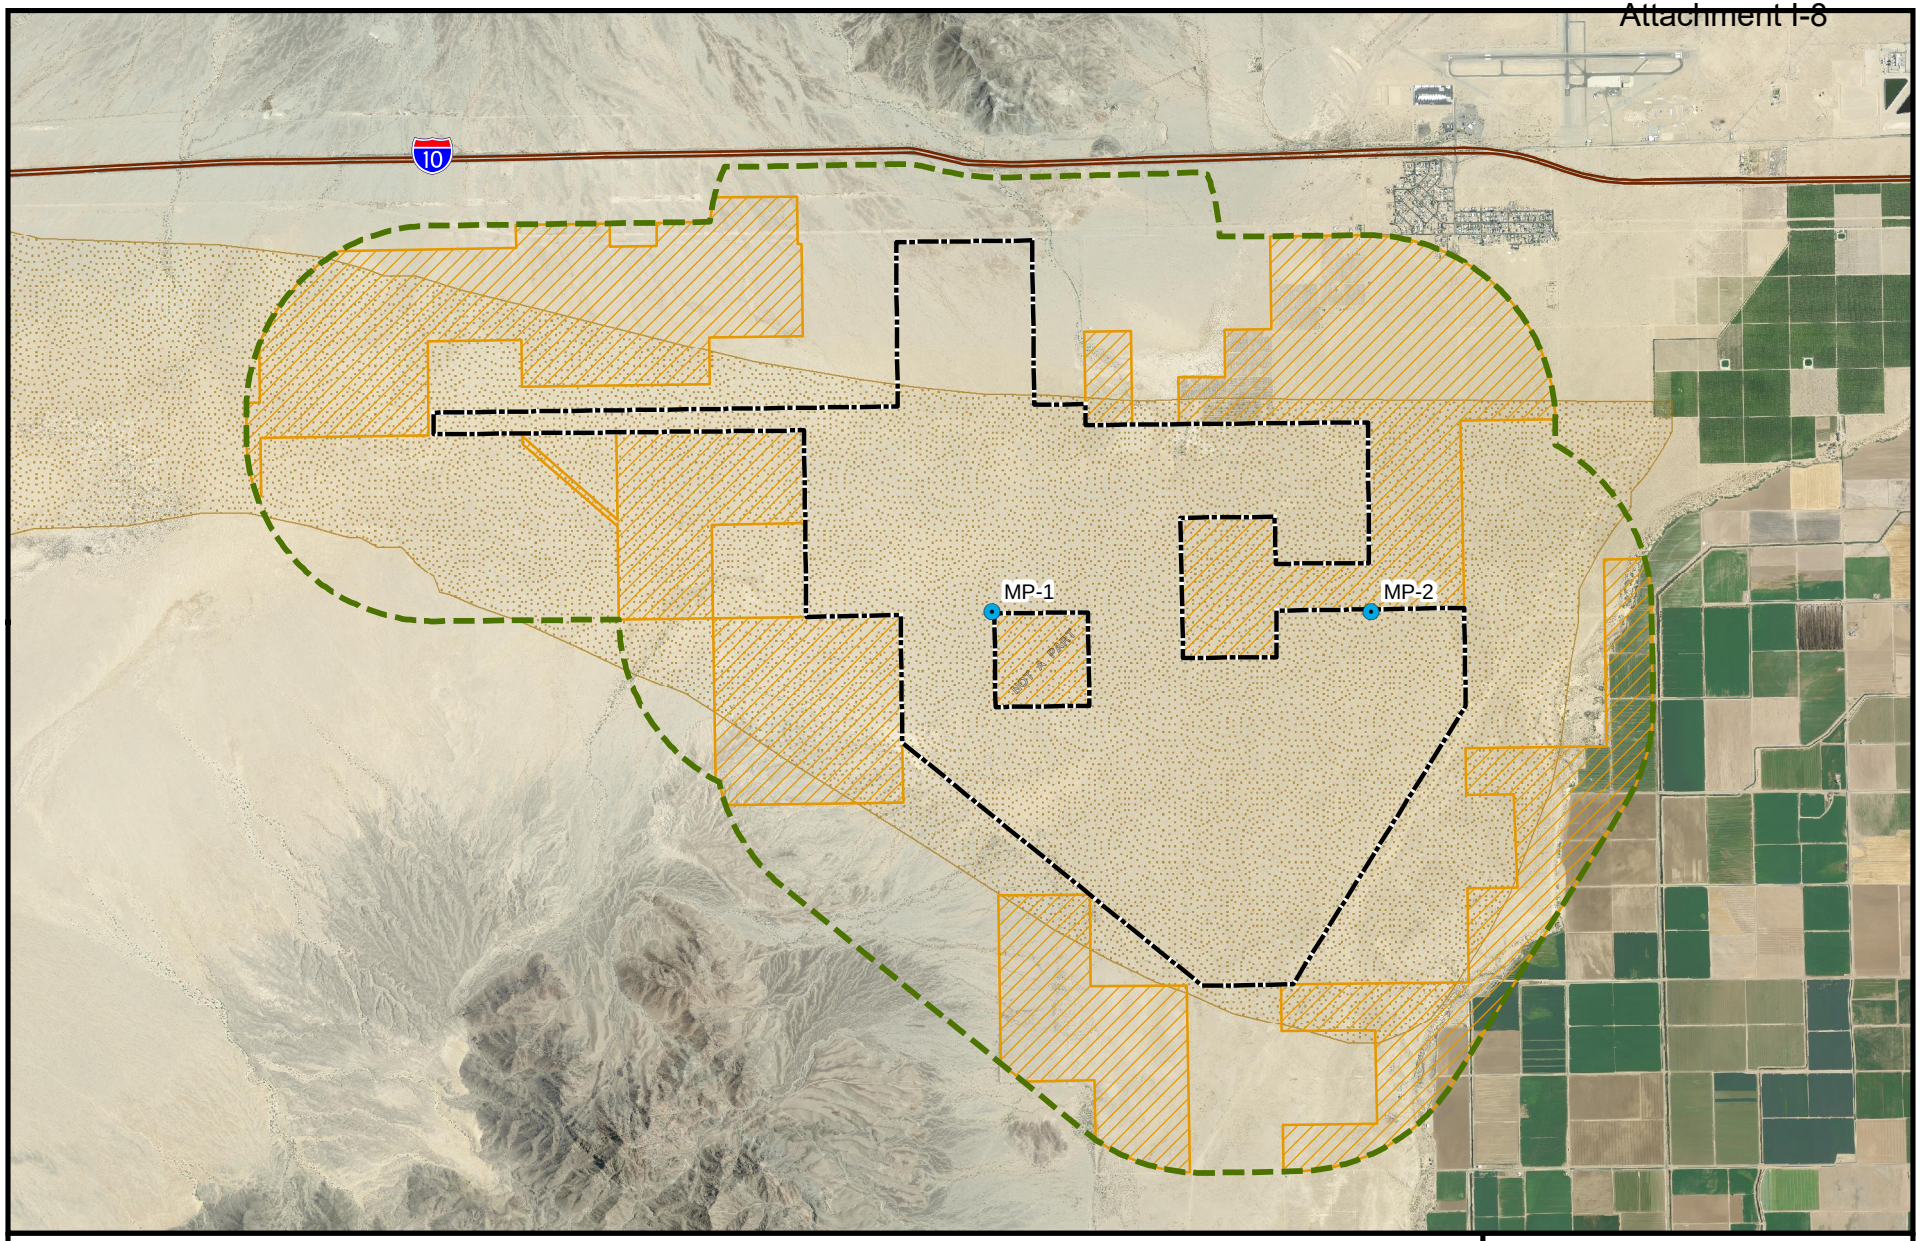
Tracks		Age	Location

2.9.2 Mojave Fringe-Toed Lizard and Herpetofaunal Surveys

Three herpetofaunal surveys were completed on the Project site. Two preliminary baseline herpetofaunal investigations (October 22-23, 2012 and March 25-April 12, 2013) and one Visual Encounter Survey (April 10 -25, 2013) were completed. Twenty-one qualified and trained field wildlife biologists took part in the surveys.



Preliminary herpetofaunal baseline investigations had two objectives; 1) to census extant squamate populations and 2) identify and determine species of concern and/or their required habitat. Sampling took place in three distinct bouts; twice during 100 percent coverage surveys. The herp surveys consisted of walking belt transects approximately 10 m (33 ft) wide to provide 100 percent (full) coverage of the entire Project site.

The Visual Encounter Survey, which is a more intensive survey, was also conducted. This survey was employed to augment the incidental data collected during the 100 percent coverage wildlife surveys. Using the 12 baseline sampling points employed by the avian, botanical, and small mammal teams, 12 transects were set up (ten on site and two in the buffer zone) and sampled using visual encounter surveys (Figure 4). Six different wildlife biologists were used to carry out these surveys across five different times of day over two weeks. Transects were intensively searched and although localized effects had been exhibited by various sampling points, when viewed on the whole, the data bore out similar data collected by the wildlife biologist crews.

2.10 AVIAN

During peak migration periods in the spring and fall of 2013, an agency-approved avian biologist conducted a survey at each MP, once per week, using unlimited-distance bird migration survey methods (Table 3). Figure 6 (below) shows the location of the MPs within the proposed Project site.

2.10.1 Line Transect Sampling

The purpose of these surveys is to depict avian use patterns at and adjacent to the Project site. Data will provide information on the following:

- Sedentary and migratory populations;
- Species richness (number of different species present);
- Species diversity (species richness combined with species evenness);
- Species use, behavior and movements; and
- Species distribution across the project.

Qualified biologists conducted surveys during the spring of 2013, recording all species observed and documenting their site use. Surveyors followed a sampling model that implemented a line-transect survey methodology. The project-specific survey protocols are available in Appendix D and Appendix E.

Survey results will be used in the development of an avian risk characterization (illustrating species use and occurrence within the proposed Project site) as part of the Bird and Bat Conservation Strategy (BBCS).

Line-transect sampling was conducted by traveling a pre-determined route and recording all bird detections (visual or aural) on either side of the transect line. The distance a bird was detected from the transect line was estimated and recorded as an absolute measure. The observer scanned the sky as well as the surrounding habitat and recorded bird use and movement data under good weather conditions, good visibility, no sustained precipitation and average wind speeds less than 15 miles per hour (mph). Each line-transect was surveyed in an effort to capture species occurrences and temporal site use through the spring season. Surveys were timed to capture migrants, breeding birds and local residents.
Information recorded during the line-transect sampling included the following:

- Transect start time;
- Species identification;
- Number of birds seen;
- Flight height;
- Time of day;

- Horizontal distance (perpendicular) to the survey line;
- Behavior during observation; and
- Transect end time.

Project-specific survey protocol were developed to ensure consistent data collection (Appendix D and Appendix E). A total of eight-2,000 meter long transects were established (Table 4). To facilitate robust data analysis, half (four) of the line-transects were situated within the Project site and half were located outside the Project site on public lands with similar habitat composition. One transect on-site and one transect off-site included sampling microphyll woodlands. The control to sample ratio is 1:1.

Transects within the Project site were aligned to promote continuity so that post-construction surveys could use the same transects and be unimpeded by installed solar panel arrays, if arrays are positioned where proposed (Figure 7). Transects surveys were conducted by alternating start and end points on subsequent surveys to avoid surveying a transect at the same time of day.

2.10.2 Burrowing Owl Surveys

Burrowing owl *(Athene cunicularia)* surveys were scheduled and performed according to "Staff Report on Burrowing Owl Mitigation" (California Department of Fish and Wildlife, 2012) and the *Burrowing Owl Survey Protocols and Mitigation Guidelines* (California Burrowing Owl Consortium 1993). Phase II burrowing owl surveys (California Burrowing Owl Consortium 1993) were conducted across all portions of the Study Area.

DESERT QUARTZITE SOLAR PROJECT
DESERT QUARTZITE, LLC

Figure 7

Line Transect Locations

AR060502

Wildlife crews surveyed the entire proposed Project site walking belt transects with 10 m spacing. Surveys within the 150-m buffer were conducted by walking straight-line belt transects spaced no more than 30-m apart, adjusting for vegetation height and density (Rosenberg et al. 2007). During each of these survey efforts, at the start of each transect and at least every 100 m, survey crews, using binoculars, scanned the entire visible Study Area for burrowing owls. Some burrowing owls may be detected by their calls, so crews listened for burrowing owls while conducting the survey. Care was taken not to "flush" burrowing owls from their burrows and to minimize disturbance near occupied burrows during all seasons.

Burrowing owl sightings and burrows with burrowing owl sign (including: whitewash, tracks, pellets, feathers) were mapped and recorded using standardized data forms. Burrows were recorded as used by burrowing owls if one or more burrowing owls were present, or if sign (i.e., pellets, prey remains, whitewash, or decoration is present) was detected.

Avian biologists followed up on each of the detections originally recorded by wildlife survey crews. This follow-up effort included incidental detections made by biologists during the fall of 2012 and spring of 2013 surveys. Any burrow with associated burrowing owl sign was ranked by Class (1 to 4) depending on the age and type of sign present. Burrow Class are defined as follows:

- 1=Excellent (Usable burrow with burrowing owl present);
- 2=Good (Usable burrow, fresh sign but no burrowing owl present);
- 3=Fair (Usable burrow, inactive with old sign, no burrowing owl present); and
- 4=Poor (Inactive, burrow, no burrowing owl sign).

Phase III burrowing owl surveys, extended observation surveys, were conducted on all burrows that had associated burrowing owl sign. This included all burrows ranked in Classes 1 through 3 as described by the Burrow Class conditions above. Phase III monitoring efforts were conducted from as many fixed points as necessary to provide visual coverage of the site using spotting scopes or binoculars. These surveys were performed between morning civil twilight and 10:00 AM and two hours before sunset until evening civil twilight.

2.10.3 Golden Eagle Surveys

Agency approval of the Quartzite Avian Work Plan was not granted until after the 2013 golden eagle (*Aquila chrysaetos*) breeding season ended. It is anticipated that migration surveys, scheduled for the spring 2014 season, will provide sufficient additional data points to adequately cover all bird usage.

In addition to Unlimited Distance Extended Observation Surveys, eagle surveys following the *Interim Golden Eagle Inventory and Monitoring Protocols*; and other recommendations (Pagel *et al*., 2010) were performed in the winter of 2013/2014 (December 16-20, 2013 and January 16-20, 2014). Surveys for

breeding and non-breeding bald and golden eagles were conducted within a 10-mile radius of the Project site. Occurrence of non-breeding golden eagles within at least 10 miles of the project boundary during the courtship season (*e.g.*, late December through early February) will be documented and be used to estimate potential project-related impacts to golden eagles, including: juveniles, sub-adults, adult floaters, and breeding adults.

Avian surveyors used historic nest data to model golden eagle habitat and assess the terrain for suitable nest sites within a 10-mile buffer of the proposed Project site. Surveyors have determined territory occupancy within known and potential golden eagle territories through extended observation periods (Pagel *et al*., 2010).

Golden Eagle survey data includes:

- Assign identification number;
- Record Universal Tranverse Mercator (UTM) location via GPS;
- Assess any nests for condition (fresh greens, good, fair, old and decrepit); and
- Record any birds present (species, behavior).

Surveyors utilized high-powered spotting scopes from the greatest effective distance possible during the breeding season.

2.10.4 Elf Owl Surveys

Elf Owls (*Micrathene whitneyi*) are small cavity nesters typically inhabiting desert areas overgrown with saguaro cacti, and mesquite or deciduous riparian woodlands and adjacent tablelands. They are found in ravines, canyons, plateaus, and on mountain slopes.

In July 2013, an owl-specialist biologist, Dorothy Crowe with Great Basin Bird Observatory (GBBO), toured the Project site to determine whether habitat suitable for nesting elf owls was present. Dorothy Crowe was given a comprehensive tour of the project area and a surrounding one-mile buffer zone, and examined some habitat features just outside of the one-mile buffer that merited attention. She took extensive notes on her observations, and recorded coordinates of any notable features.

2.10.5 Nesting Raptor/Raven Surveys

Nesting raptor/Raven survey efforts focused on the detection of all raptor/raven nests within 1-mile of the Project site in order to collect baseline data on the following.

- The number and distribution of raptor/raven nests prior to project development; and
- Success rates of raptor/raven nests prior to project development.

All bird nests (including the incidental detection of resident passerine species) were mapped and recorded on standardized datasheets. Monthly monitoring efforts were completed to update the datasheets to include the development stage and breeding status at each raptor/raven nest.

2.11 MAMMALS

There were three mammal surveys performed for this Project; small mammal trapping, desert kit fox and bats.

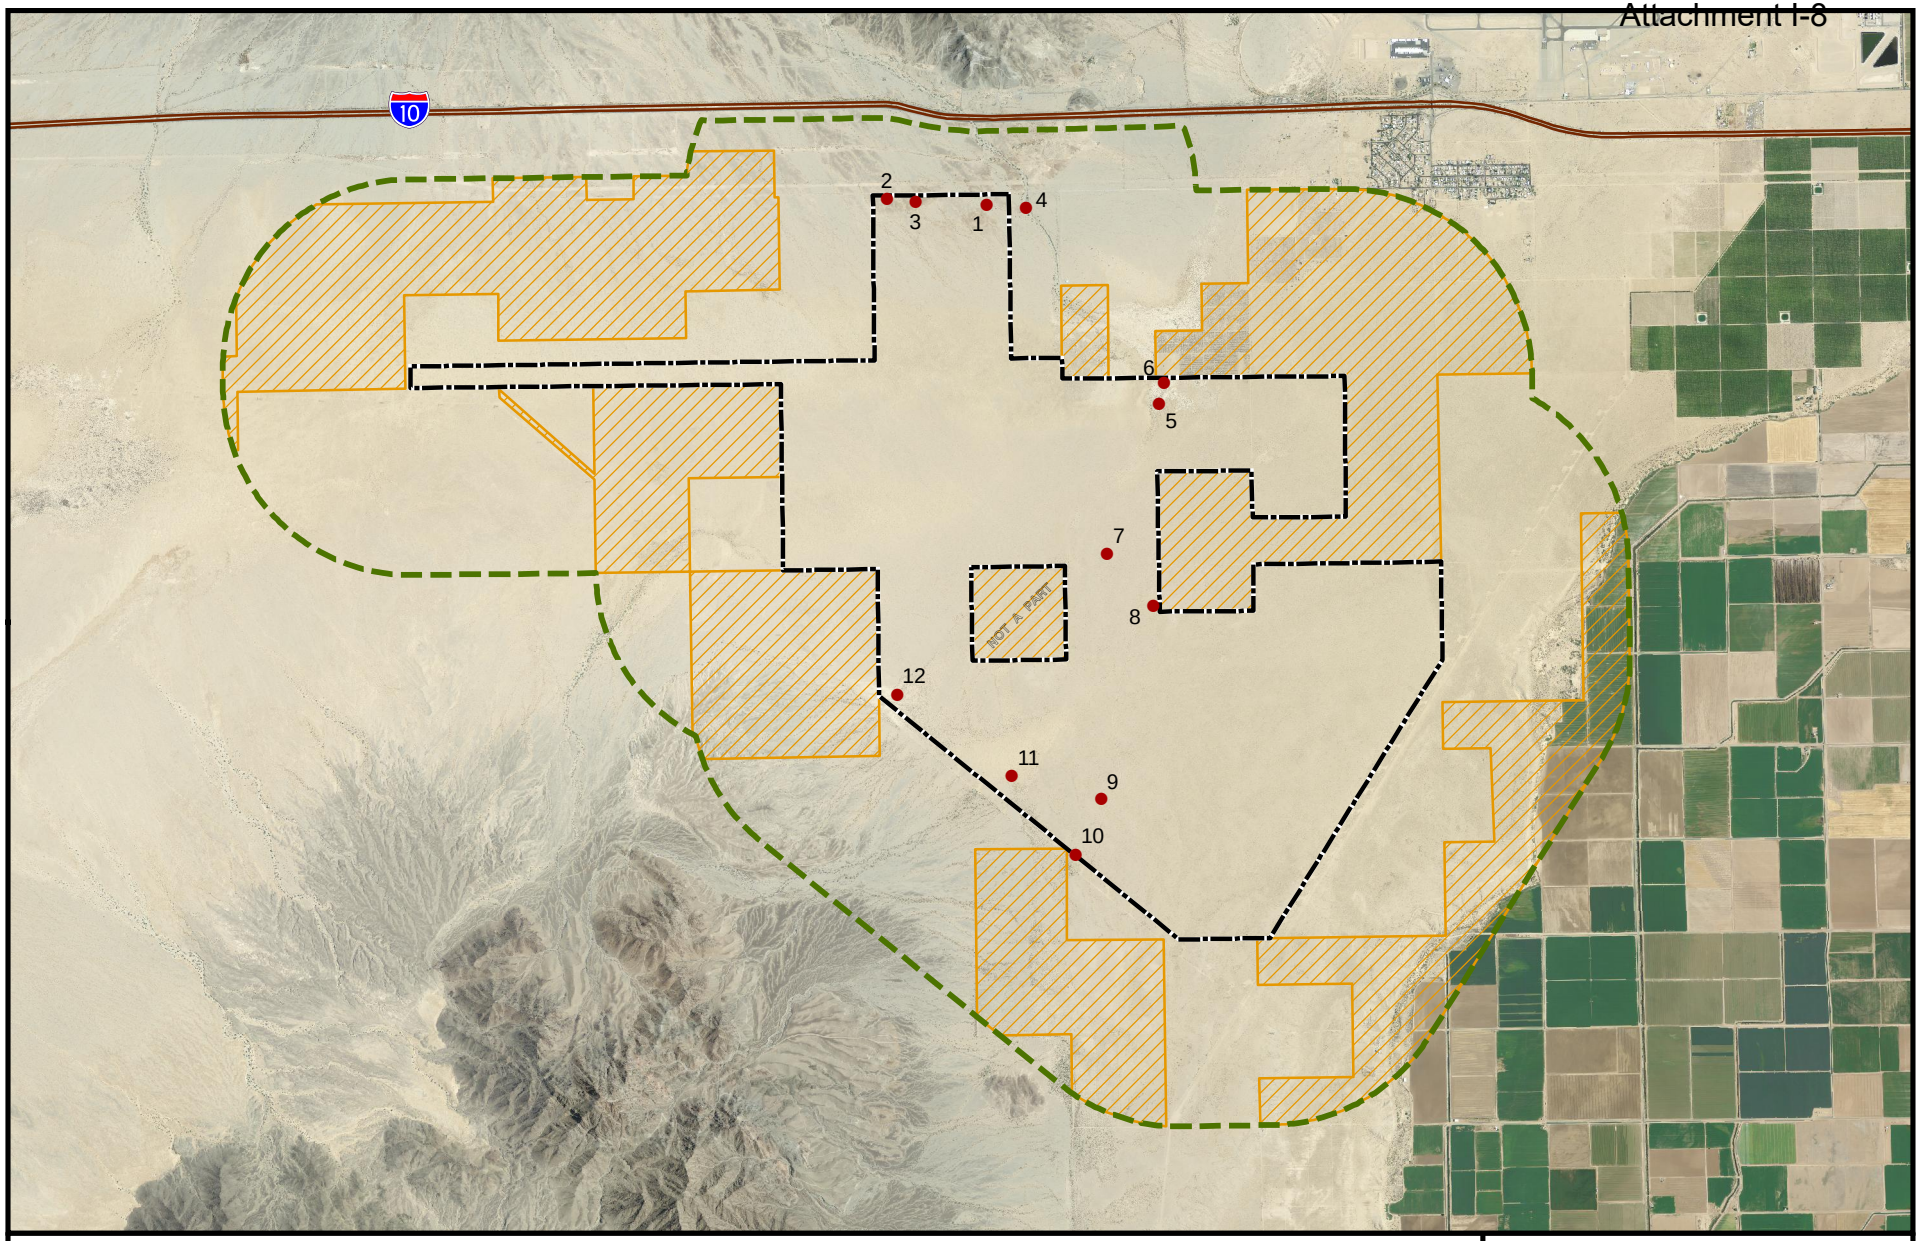
2.11.1 Small Mammal Surveys

Small mammal surveys were performed to document species types, abundance and locations. Trapping grids were established at all baseline survey locations. Narrow grids consisting of 100 Sherman large (12 inches) live-traps were set at each location. For most baseline locations, the sampling location point represented the southwest corner of the trapping grid. Depending on the width of the habitat being sampled, either a 10 by 10 configuration or a 4 by 25 configuration was used. All traps were spaced approximately 10 m apart. Trapping grids were run for three consecutive nights at all baseline locations. Traps were opened near sunset and checked and closed at sunrise. Traps were not opened if scheduled temperatures were estimated to drop below 50 degrees Fahrenheit. Traps were baited with standard small mammal bait, which consisted of a mixture of birdseed, rolled oats and peanut butter. Individuals found in the first two morning checks on each grid were marked with a colored sharpie marker to indicate recapture status.

2.11.2 Desert Kit Foxes

Surveys of the Project site were conducted by qualified biologists walking transects at 10 m spacing to ensure total visual coverage of the area. All desert kit fox single-entrance dens and canid complexes that could be occupied without modification were recorded. A camera station was set up at a total of eight dens and run for three consecutive days and nights.

A qualified biologist revisited each of these 24 dens to search for signs of activity such as lay-down spots on the entrance mounds and make a determination of active status. Up to 16 of the most active dens were monitored with cameras for three nights each. Photo images were analyzed to attempt to identify individual foxes and their sex and age group to try to determine a rough demographic index of desert kit fox presence on the Project site.



2.11.3 Bats

A bat assessment was performed by Patricia Brown, Ph.D. and William Rainey, Ph.D. (Brown-Berry Biological Consulting) to assess potential bat habitat within the Study Area. Suitable roosting and

foraging habitat for several bat species that are known to occur in the vicinity (including pallid bats, cave myotis and California leaf-nosed bats) was reviewed in the field.

Acoustic monitoring was conducted for three nights to sample bat species utilizing the Study Area (Figure 8). Passive acoustic monitors consisted of a sealed enclosure containing a battery, broadband frequency-dividing ultrasound detector and a programmable data storage device (Anabat II and CF-ZCAIM; Titley Electronics, Ballina, NSW, Australia), with an extension cable microphone in a weather shroud, flat acoustic reflector and bracket (P). The microphone and reflector assemblies were elevated approximately 3 ft above the terrain on a metal stake (Photograph 1). Recorded data were stored on compact flash cards that were programmed with sampling start and stop times (1800-0600 PST) for a sampling interval longer than the time from local sunset to sunrise. An estimate of local sunset times (ignoring local horizon topography effects) was obtained from project site coordinates and U.S. Naval Observatory web services (http://aa.usno.navy.mil/data/docs/RS_OneYear.php). Twelve monitors were deployed (Figure 8) at sites with different vegetative components to identify bat species and document activity levels at this season. Half of the monitors had standard microphones and half had low frequency microphones with higher sensitivity to sounds in the audio range (4.5 to 20 kilohertz (kHz)). This enhances recording of certain bat sounds (e.g., pallid and California leaf-nosed bat social calls, western mastiff and other free tail bat calls) along with insect and bird calls.

X:\GIS\Ironwood\Desert Quartzite\pdf jan 2014 steph photos\Photo 1.CDR

Photograph 1 - Detector 5, microphyll woodland.

Roost surveys were conducted of mines in the mountains adjacent to the project area during the day and at night for evidence of bats and guano. Two mines in the southern McCoy Mountains (located approximately 4.4 miles northwest of the Study Area) had previously been identified by Dr. Brown as California leaf-nosed bat maternity colonies and had been gated with bat-compatible closures by the Bureau of Land Management in 2011. These mines were monitored on May 8, 2013 at dusk by surveyors with night vision equipment to obtain accurate exit and entry counts of bats and acoustic records with additional Anabat detectors. The surveyors kept two counts, entry and exit, for at least sixty minutes after the first bat exited of how many bats entered and exited the mines. Video cameras with auxiliary infrared lights were used to remotely monitor mines and to obtain permanent records of exiting bats.

Using topographic maps and Google Earth images, ground reconnaissance was conducted of possible mine features on the north end of the Mule Mountains (1.8 miles south of the Study Area) and no underground features that could shelter bats were discovered. The closest known bat colony in the Mule Mountains is the Hodge Mine (a.k.a. Stonehouse, 33.51145, -114.79383) situated 3.4 miles south of the Study Area. This mine contains the largest winter colony of California leaf-nosed bats (*Macrotus californicus*) in the United States, as well as a maternity colony. It is also one of four maternity colonies for the cave myotis (*Myotis velifer*) in California. This mine has been a research site for Dr. Brown since 1976.

3.0 RESULTS

3.1 BOTANICAL STUDIES

Thirty-three special status plant species had been identified as potentially occurring in the vicinity of the Project site (Appendix F). This list was generated by searching multiple databases and reference sources for occurrence records.

3.1.1 Special Status Plant Species

The fall 2012 survey was conducted September 11 -19, 2012, and spring surveys were conducted March 18-30, 2013. There was very good localized winter rainfall for each of the surveys, enough to germinate abundant annual blooms, and timing was excellent for observing and identifying all potentially occurring target plants. For the fall survey, full coverage at 10 m spacing was achieved across the entire Study Area. Fall and spring surveys across the site yielded a full plant list of 124 taxa, representing 25 plant families. Of this total, 114 are native, and 10 are non-native. The floristic plant list is in Appendix F.

3.1.1.1 Special Status Plants Found on Site

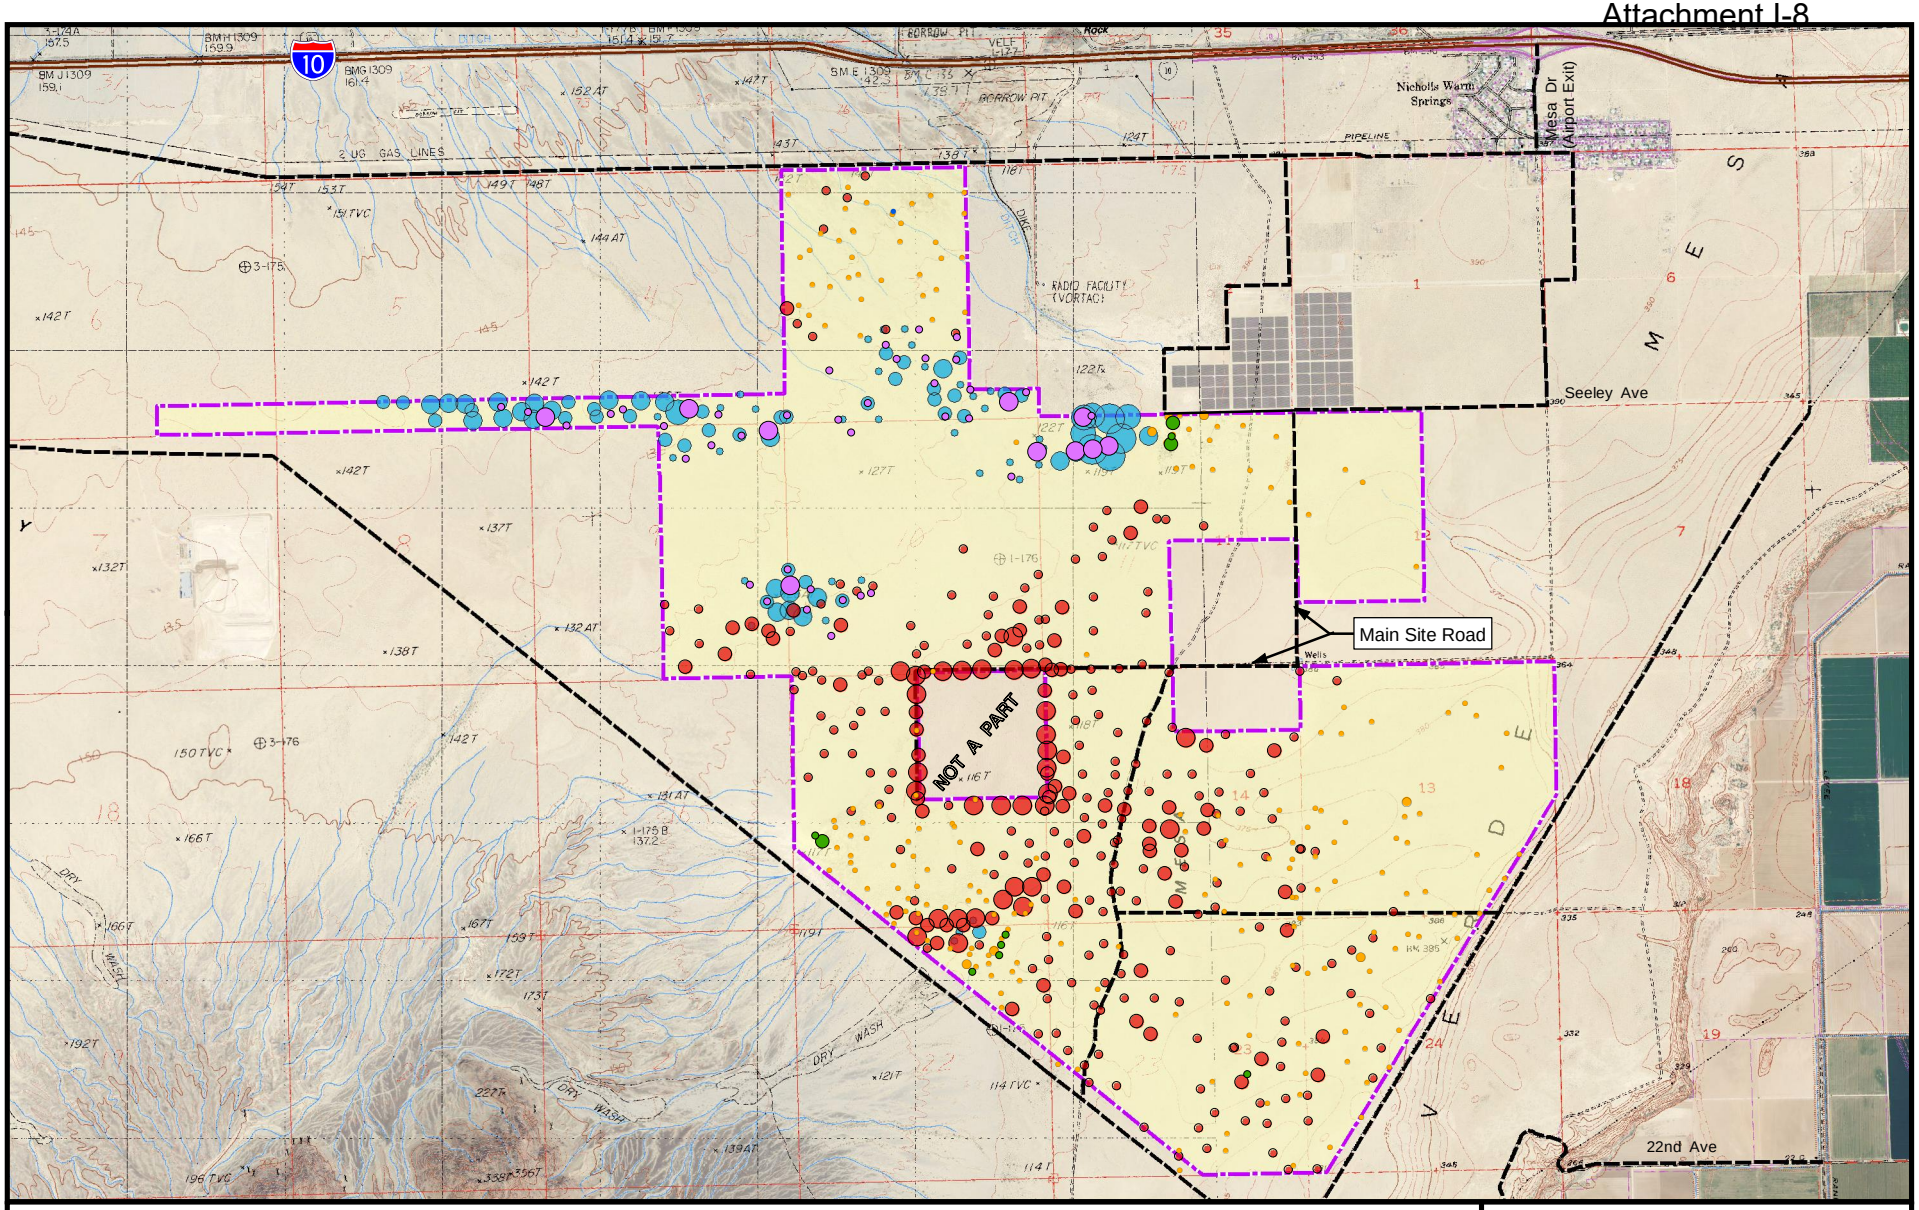

Table 5 below lists all the Special Status plants found onsite during fall and spring surveys. None of these plants are federally or State Listed, but they all qualify as Special Status to different degrees by California State-ranking and CNPS ranking.

Table 5 Special Status Plants Found on Site

DESERT QUARTZITE, LLC

Figure 9

Combined Rare Plants Map

AR060512

3.1.1.2 Harwood's Milkvetch

Harwood's milkvetch is a CNPS Rank 2.2 annual herb in the Fabaceae family. It is historically known to occur in desert dunes and Mojavean and Sonoran desert scrub at elevations ranging from 0 to 2,300 feet (0 to 710 meters) amsl.

Large populations of Harwood's milkvetch, were documented in the spring 2013 survey (Photograph 2) (Figure 10). It was so abundant in certain areas; the surveying botanists estimated numbers of individuals per waypoint. The total estimated count across the site was 13,712 individuals. It is distributed widely across most of south half of the Project site, with concentrated populations along the disturbed berm surrounding the existing (abandoned) Jojoba farm, and some very shallow sand dunes at the southwest corner of the site. Its mechanism for dispersal is unknown, but most likely its inflated seed pods get carried by the stiff westerly winds and deposited at some wind-breaking disturbance such as soil berms.

The majority of the plants were in fertile condition, often both flowering and fruiting, and there appeared to be a robust fruit and seed set this spring. There is certainly a significant seed bank in the soil after this spring.

Other nearby solar projects (McCoy and Bylthe) also documented large occurrences of this plant. These projects are in advanced stages of approval and share a common right-of-way with this proposed Project's gen-tie line location.

This Project's populations, however, are mostly spread across the main solar site, and the impacts may be greater. The proposed methods of site development involve intensive and comprehensive soil surface disturbance by grubbing, grading, compaction, and application of soil surface stabilizers. This type of development inhibits re-establishment of natural plant communities: essentially nothing is allowed to grow between the panels. Harwood's milkvetch has a State Rank of 2, and a CNPS Rank of 2.2, which means that it is fairly endangered in California, but more common elsewhere.

(Astragalus insularis var. harwoodii)
Distribution

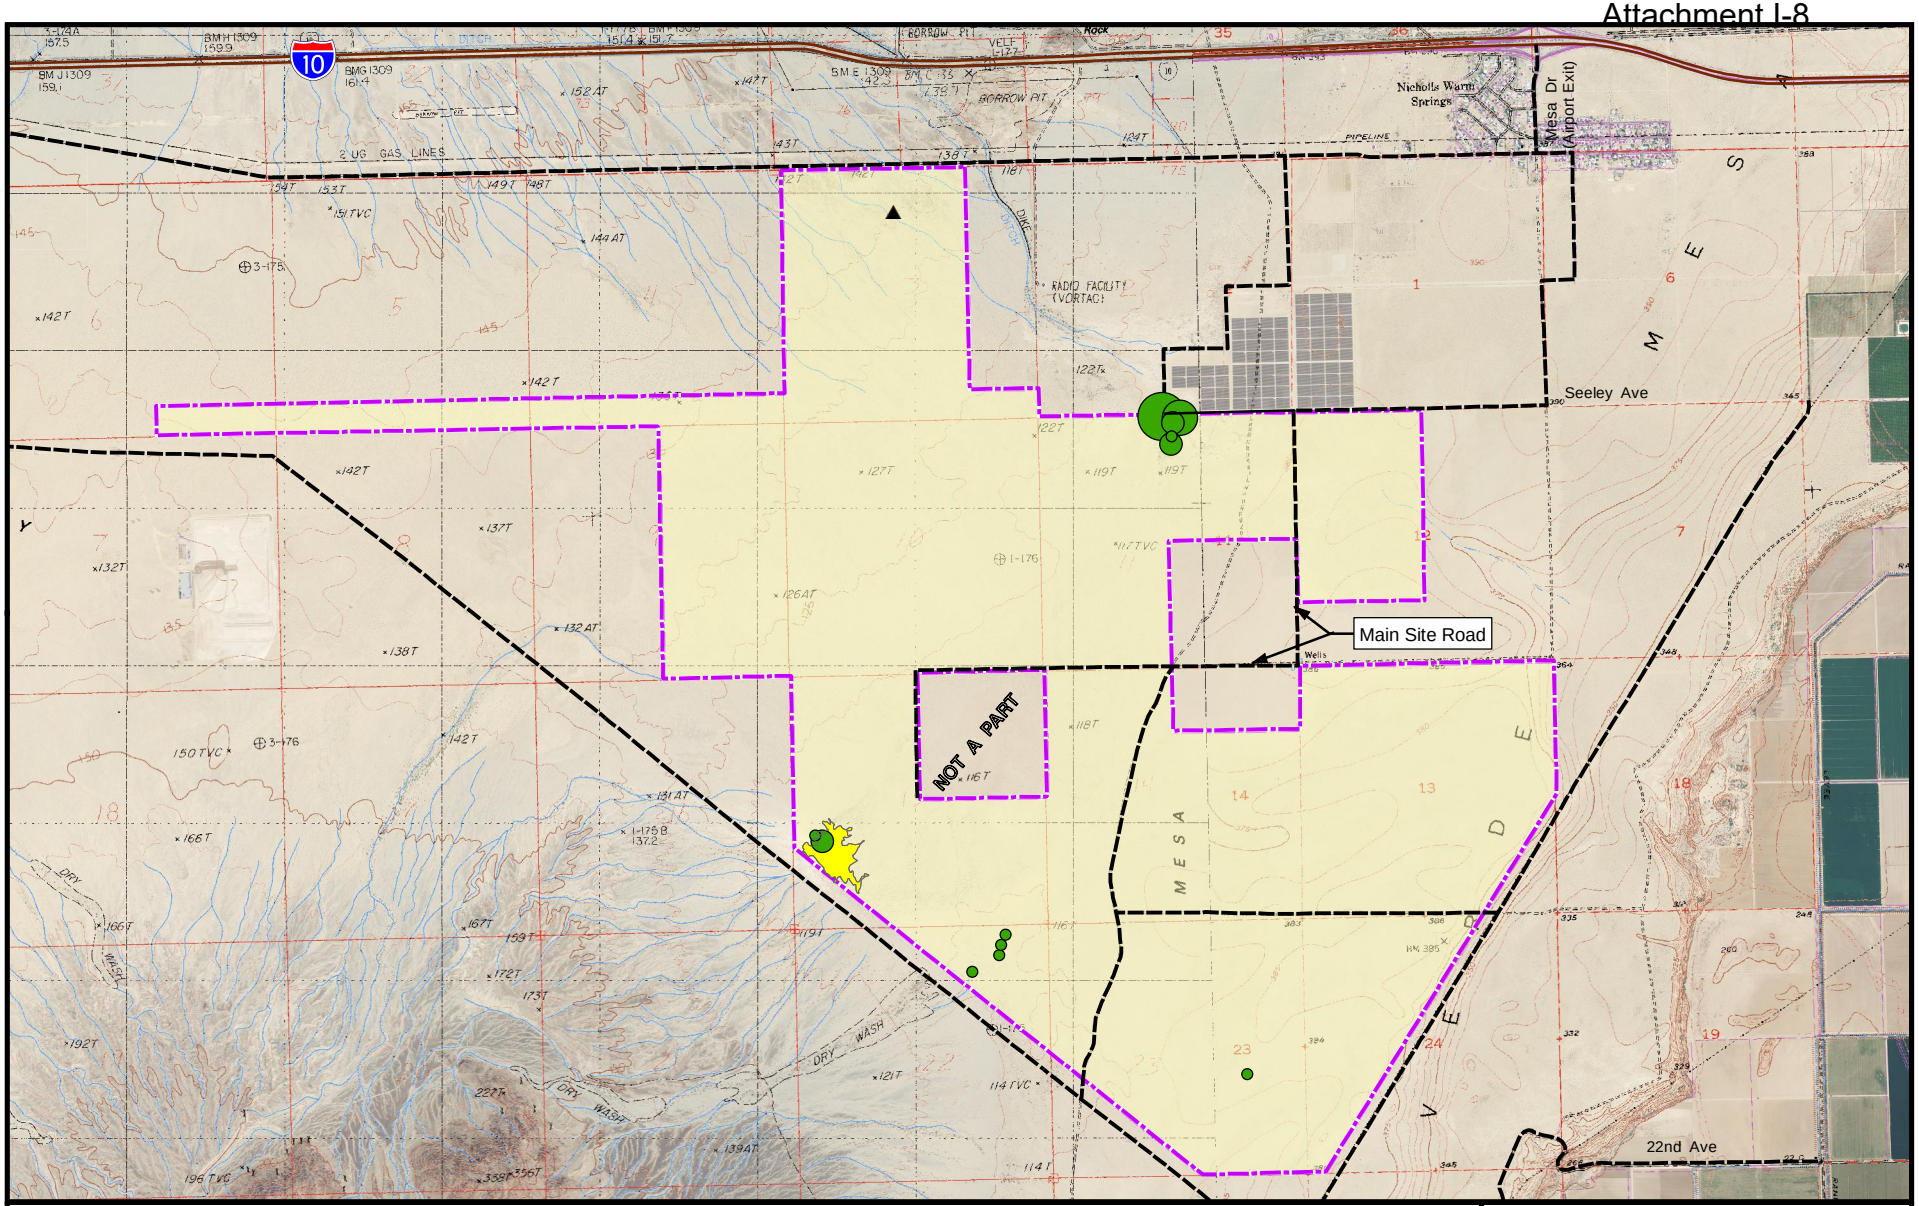
AR060515

3.1.1.3 Abram's Spurge

Abram's spurge is a CNPS Rank 2.2 annual herb in the Euphorbiaceae family. It is historically known to occur in Mojavean desert scrub, playas, and sandy/silty Sonoran desert scrubs at elevations ranging from sea level to 3,000 feet (0 to 915 meters) amsl.

It was documented as a few small occurrences and one large population during the fall 2012 surveys (Photograph 3) (Figure 11). The total number of individuals was estimated to be approximately 2,104, the majority of these existing as depauperate dwarf plants on a cracked-muddy flat at the southwest border of the site (called "population 1" in this document).

The regional distribution of Abram's spurge and its concept of rarity have been undergoing some revision lately. Recent surveys on the McCoy Solar Project have yielded over 4,000 individuals, and reports of populations in the "tens of thousands" have been observed on Ford Dry Lake and Hayfields Dry Lake (Karl, Pers. comm.). Due to its fall-blooming phenology, this plant may have been overlooked during most botanical surveys, which typically occur in the spring. Consequently, its Special Status in California is presumed to be due to under-sampling.



Nonetheless, because of its State Ranking of S2 and CNPS Ranking as 2.2, any unavoidable disturbance will most likely require mitigation.

3.1.1.4 Utah Vine Milkweed

Utah vine milkweed is a perennial herb in the Apocynaceae family. It typically grows along wash margins and in sandy/gravelly areas throughout the Sonoran and Mojave deserts of California, sprawling and clambering over common shrubs for support. Flowering from April to September, its elevation range is 300 to 4,700 feet (100 to 1,436 meters) amsl.

Only one small individual of Utah vine milkweed was observed onsite in the spring 2013 survey (Figure 11). It was located near the northern most border of the site in a shallow runnel margin. This is an insignificant occurrence, especially with respect to large distributed populations found on the McCoy (5,180 individuals) and Blythe Solar sites (398 individuals). Utah vine milkweed has also been widely documented during solar project surveys across California and Nevada, and appears to be much more common than previously thought.

3.1.1.5 Ribbed Cryptantha

Ribbed cryptantha is an annual herb in the Boraginaceae family. It occurs on fine sandy soil and shallow dunes within Sonoran and Mojavean creosote bush scrub, at an elevation range below 3,200 feet (1,000 meters) amsl. Flowering from January through May, it has been widely documented from California herbarium records, with several occurrences within five miles of the Quartzite project site, as well as a reference population near the site.

The spring 2013 surveys documented approximately 56,748 individuals of ribbed cryptantha, exclusively on sandy areas of the site (Photograph 4). Some occurrences were so dense that then numbers of individuals were estimated systematically. Very dense populations were recorded along the gen-tie line and on sandy areas southwest of the exiting solar facility (Figure 12).

From the many solar project surveys conducted throughout the region, several large populations of ribbed cryptantha have been documented. A total of 1,715 individuals, were observed at the McCoy Solar site mostly around the sandy gen-tie line alignment to be shared with both the Blythe Solar project and this Project. Blythe Solar recorded around 71,000 individuals along the same gen-tie line, but this number also includes individuals counted on the footprint of the substation (already built).

The main threats to this species are: major disturbances of sandy areas; disruption of sand transport processes and flows; and further introduction of weeds, especially Saharan mustard (*Brassica tournefortii*). Many of the sandy locations of the site are already infested with Saharan mustard, and construction of the gen-tie Line most likely will increase this weed. The large population on sandy areas just southwest of the existing solar facility is on the Project site. These areas are highly populated with Saharan mustard, but mostly at the margins of the sand dunes

3.1.1.6 Harwood's Eriastrum

Harwood's eriastrum is an annual herb in the Polemoniaceae family. It is a California endemic, distributed on sand dunes in desert areas of Riverside, San Bernardino, and San Diego counties. Typically flowering from March to May, its elevation range is 400–3,000 feet (125 - 915 meters) amsl.

Spring 2013 surveys on the Project site documented 882 individuals of this plant, exclusively on sandy areas of the gen -tie line and Survey Area (Photograph 5) (Figure 13). Harwood's eriastrum appears to co-occur sympatrically with ribbed cryptantha, with similar substrate preferences and distribution, although in fewer numbers and more sporadically dispersed. It is vulnerable to the same threats, especially weeds as discussed in Section 3.1.4.

Figure 13

Harwood's Eriastrum
(Eriastrum harwoodii)
Distribution

AR060521

Other nearby solar projects have likewise documented populations of Harwood's eriastrum on the same sandy gen-tie line alignment. A total of 386 individuals were found on during the survey for the McCoy site. A total of 2,134 individuals were found during the survey for the Blythe Solar project that included the many found at the already-built substation.

Although Harwood's eriastrum is assigned the State Rank of S3 (apparently requiring no compensatory mitigation), its CNPS Rank is 1B.2. This is the highest Special Status ranking of any of the plants on the Project site.

3.1.1.7 Desert Unicorn Plant

Desert unicorn plant is a perennial herb belonging to the Martyniaceae family. It is historically known to occur in sandy Sonoran desert scrub at elevations ranging from 490 to 3,280 feet (150 to 1,000 meters) amsl.

811 individuals of desert unicorn plant were documented within the Study Area during fall 2012 Rare Plant Surveys (Photograph 6) (Figure 14). This is an estimate because sometimes a single root tuber might produce two to three above ground leaf rosettes, and closely spaced aboveground stems were counted as separate individuals.

Desert unicorn's distribution across the Project site followed no particular pattern. It was found occasionally on shallow sand sheets, but was mostly seen in innocuous creosote bush scrub, on both loose sandy-gravelly soils, and silty areas. It prefers shallow swales where summer monsoonal rainfall collects and soaks-down. The largest concentrations of this plant were the silty outwash flats on the southwest border of the site, and on similar silty areas near the existing solar farm.

Since fall rare plant surveys became required for desert solar projects, our knowledge of the distribution and abundance of desert unicorn has been significantly broadened. McCoy Solar surveys recorded 662 individuals distributed across its site. Blythe Solar also conducted fall surveys in 2012, documenting 1,687 individuals with many of these re-sprouting within a recently graded access road. It is presumed that this plant is much more common than believed, but has been misinterpreted as rare because of the limited number of fall surveys performed as seen with surveys not conducted at the correct time of the year for Abram's spurge noted earlier.

3.1.2 Cacti and Yucca

Yuccas were not found on site, but three species of cactus were documented during the fall 2012 Plant Survey. Due to the fact that all cacti were already recorded, they were not documented in the spring 2013 surveys. The cacti were not recorded with GPS waypoints or in the electronic database; however, they were tallied by species on the paper datasheets by field surveyors, and represent a good census of all cacti onsite.

The estimated totals of all cacti found on site are presented as follows:

- *Cylindropuntia echinocarpa*: 106 individuals;
- *Mammillaria tetrancistra*: 11 individuals; and
- *Ferocactus cylindraceus*: 1 individual.

3.1.3 Vegetation Communities

The preliminary vegetation communities are mapped on Figure 15 and described as follows.

3.1.3.1 Desert Dry Wash Woodland

Desert Dry Wash Woodland (DDWW) is located in two distinct washes, comprising approximately 2 percent of the Project site. Desert Dry Wash Woodland habitat consists of small-leaved (microphyllous) leguminous trees, in association with sandy or gravelly washes with braided channels in active alluvial fans (Photograph 7). Dominant plants species include ironwood (*Olneya tesota*), blue palo verde (*Parkinsonia florida*), with occasional honey mesquite (*Prosopis glandulosa*). This community is considered sensitive by the California Resources Agency and BLM due its limited distribution, value to wildlife, and susceptibility to disturbance (Bureau of Land Management 2002 and Zeiner, et al., 1990). The presence of water at least on a seasonal flow regime is vital for this community to persist.

The NECO regulations consider DDWW as a sensitive resource and recommend avoidance of disturbance. There are three areas within the Study Area, which qualify as DDWW, and each of these are at the margins or borders of the proposed project. One DDWW area is just south of the existing solar facility. It is a rich woodland environment with palo verdes, ironwoods, and a few mesquites, and is good habitat for many species of avian wildlife. The second DDWW area is down by the southwest powerlines where water flows and pools from the mountains to the southwest. Fine silty soil supports a lot of unicorn plant (*Proboscidea althaeifolia*), plus a nice diversity of common native plant species. The existing project boundaries mostly avoid this area. There are, however, a few scattered palo verdes and ironwoods scattered in the scrub beyond this DDWW about one quarter to one half mile into the site. The

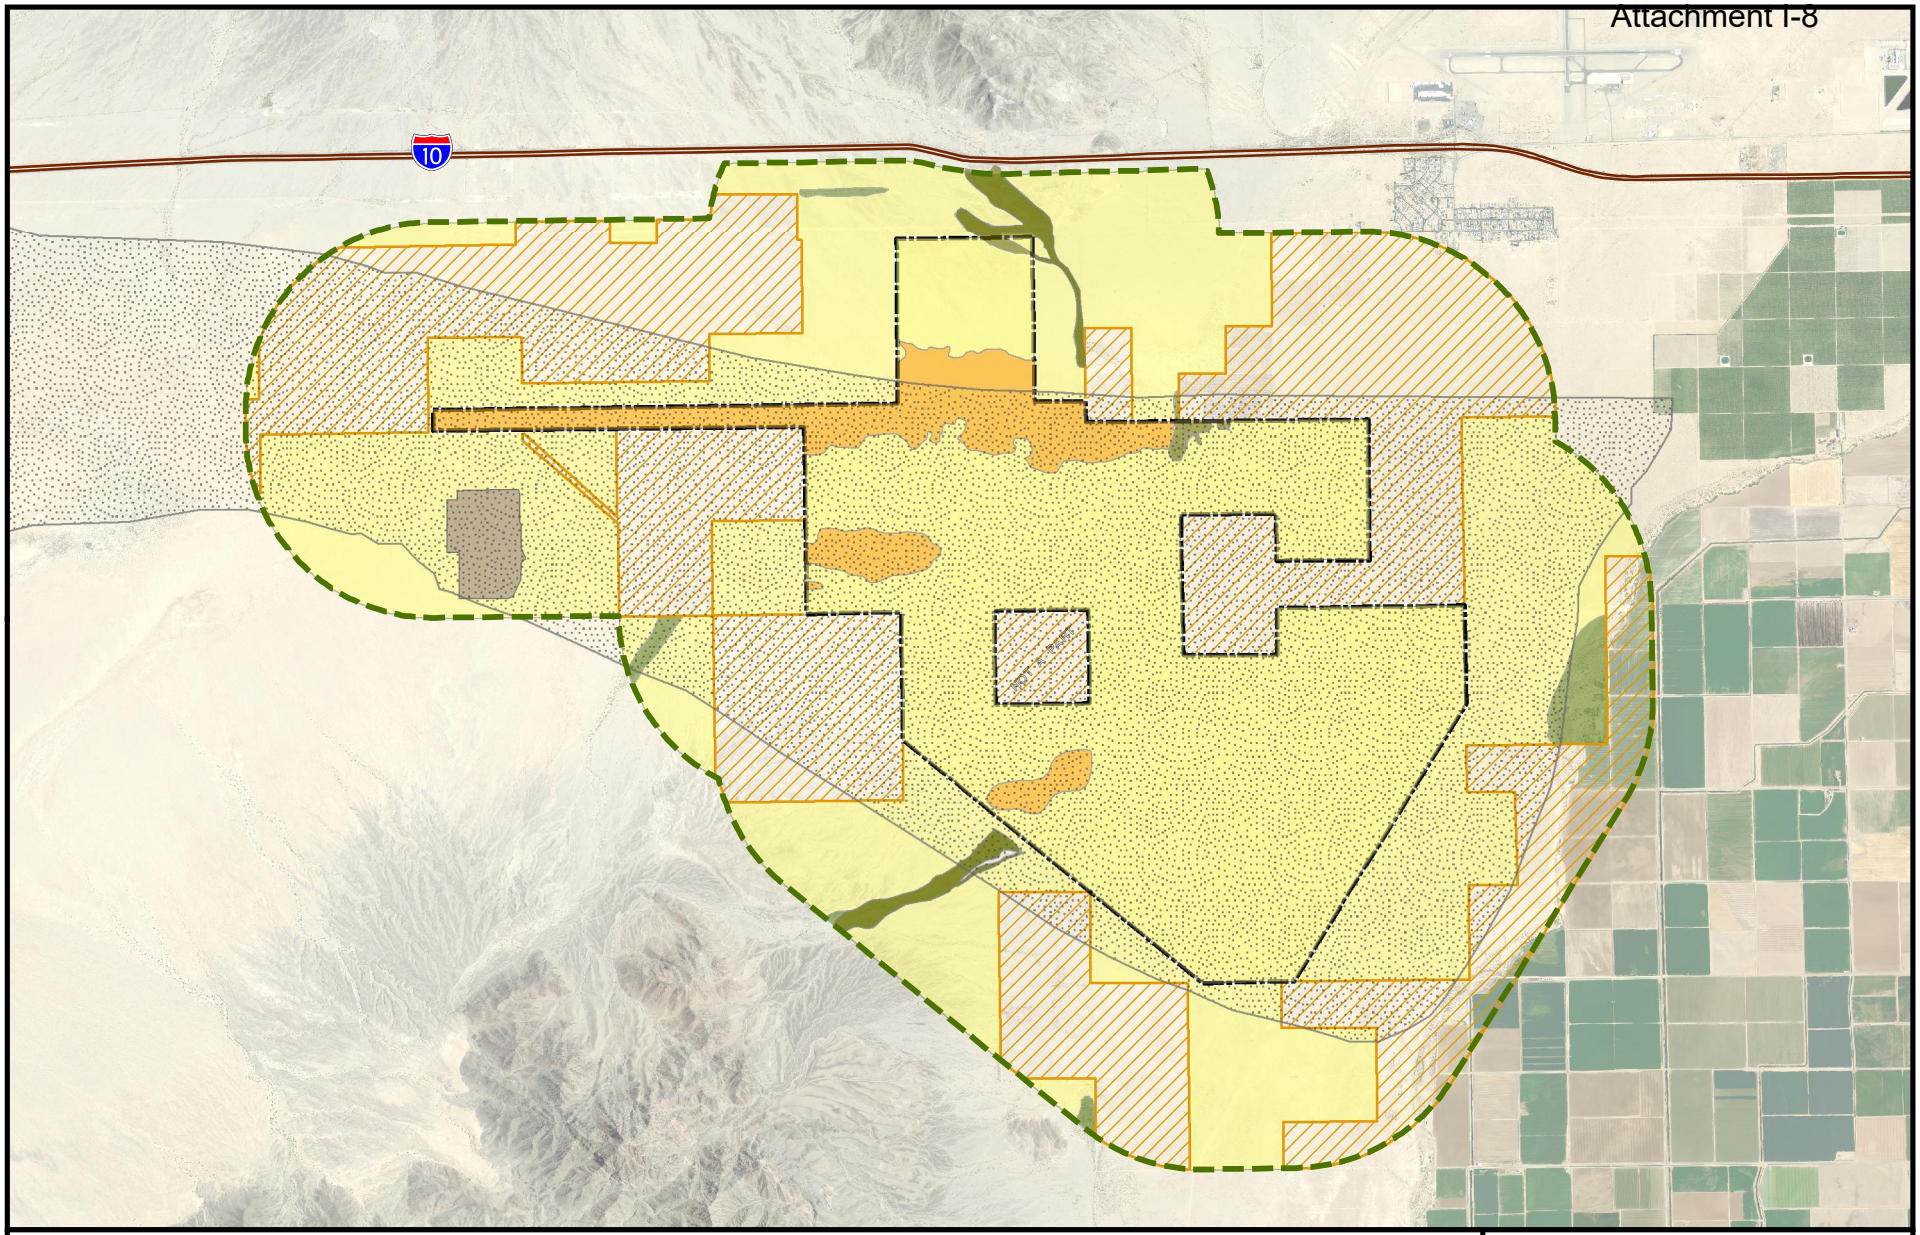
third DDWW is at the northern edge of the site, starting on the north border and running downstream in a southeast direction. There are palo verdes and ironwoods in this area.

3.1.3.2 Sonoran Desert Scrub

Larrea tridentata-Ambrosia dumosa Shrubland Alliance (Sawyer 2009)

Sonoran Creosote Bush Scrub (Holland Code 33100)

Sonoran Desert Scrub covers approximately 98 percent (7,160 acres) of the Study Area (Photograph 8) This alliance on the site is dominated by creosote bush (*Larrea tridentata*), burro bush (*Ambrosia dumosa*), with scattered occurrences of cheese bush (*Ambrosia salsola*), brittlebush (*Encelia farinosa*), Emory's Indigo bush (*Psorothamnus emoryi*), big galleta grass (*Hilaria rigida*), and occasional cactus species. Most of this onsite scrub is sparsely vegetated with widely scattered relatively low-growing individual shrubs.



3.1.3.3 Sand Dunes

Pleuraphis (Hillaria) rigida Herbaceous Alliance (Sawyer 2009)

Stabilized and Partially Stabilized Desert Dunes (Holland Code 22200)

Sand Dunes onsite are stabilized and partially stabilized accumulations supporting an herbaceous alliance dominated by the perennial bunch grass, big galleta grass (*Hilaria rigida*) (Photograph 9). Co-dominants are widely scattered creosotes (*Larrea tridentata*), with occasional occurrences of Emory's indigo bush (*Psorothamnus emoryi*), desert wire lettuce (*Stephanomeria pauciflora*), fan-leaved tiquilia (*Tiquilia plicata*) and desert dicoria (*Dicoria canescens*). This vegetation type is present on the sandiest areas around the northwest parts of the project site and along the gen-tie alignment. It is important to note that dense infestations of the invasive weed Saharan mustard are evident on many areas of this vegetation type.

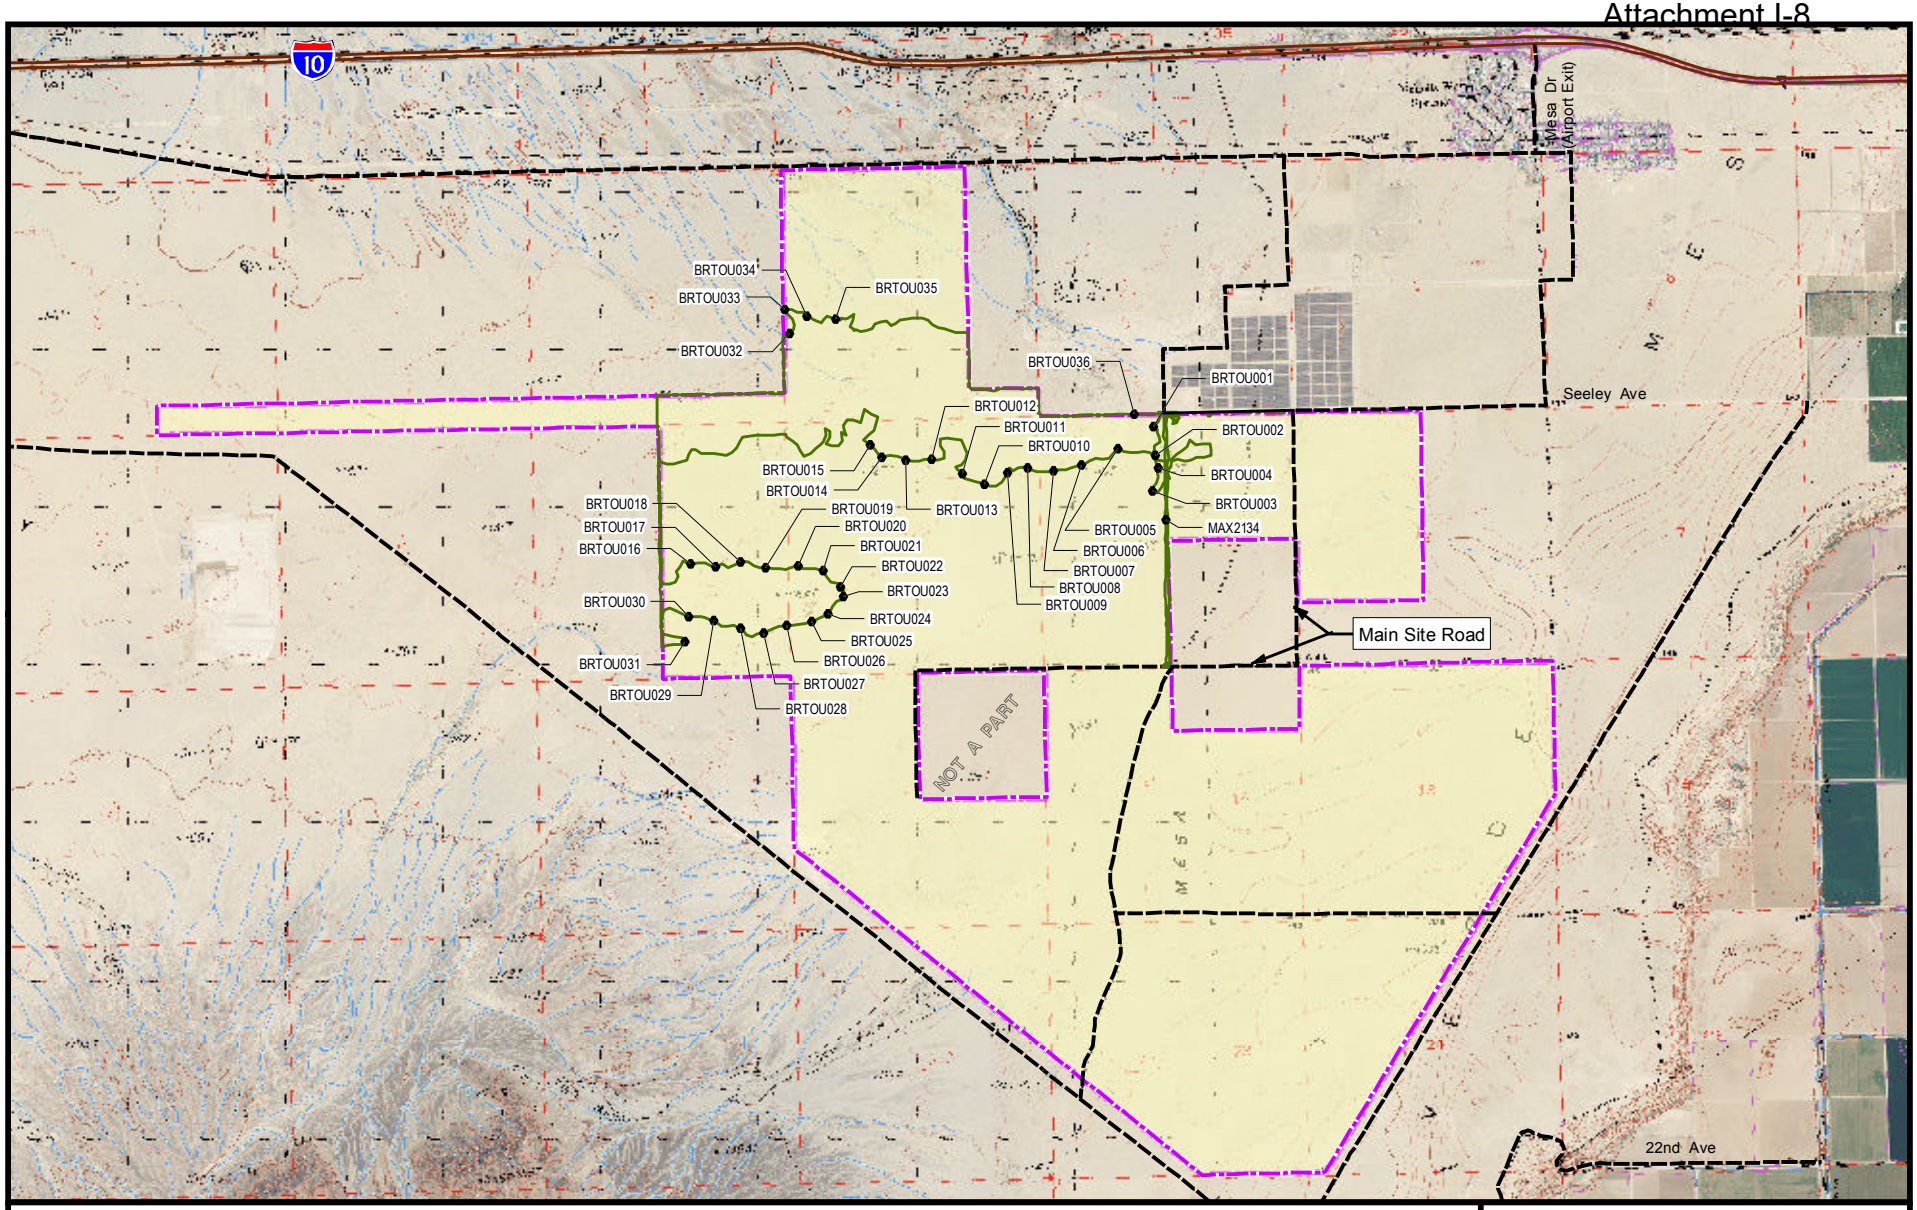
3.1.4 Non-Native and Invasive Species

Ten non-native plant species were observed on the Quartzite study area during the fall 2012 and spring 2013 Surveys (Table 6).

Table 6 Non-Native Plants Found on Project Site (Fall 2012 and Spring 2013)



Taxon	Common Name	Abundance	Invasive Potential
**Brassica tournefortii*	Sahara mustard	Widespread, Locally abundant on sand	HIGHLY INVASIVE
**Chenopodium album*	Lamb's quarters	Scarce	Low
**Chenopodium murale*	Nettleleaf goosefoot	Scarce	Low
**Cynodon dactylon*	Bermuda grass	Scarce	Invasive but unlikely
**Eucalyptus sp.*	Eucalyptus	Scarce	Low invasivity in this situation
**Polygonum aviculare subsp. depressum*	Prostrate knotweed	Scarce	Low
**Salsola tragus*	Russian thistle	Abundant on sand	Invasive on sand and disturbed areas
**Schismus barbatus*	Mediterranean grass	Widespread	Moderately invasive with little consequence
**Tamarix ramosissima*	Tamarisk	Scarce	Non invasive in this situation
**Tribulus terrestris*	Puncture vine	Scarce	Low

Sahara mustard *(Brassica tournefortii)* is by far the most aggressive and abundant invasive plant on the Project site. It is diffusely distributed throughout the Study Area on many habitats, and locally abundant throughout the sandier areas of the Project site and along the gen-tie alignment. Millions of individuals were observed flowering and fruiting during the spring 2013 survey.

Sahara mustard infestation remains the greatest invasive weed risk of the entire site. It is already well established on most of the sandier areas, and a large seed bank is certain to exist. Minimal winter rains can germinate multiple leaf rosettes, many of which can bolt and produce seed in a short time. Potential for Sahara mustard to expand its presence across other less sandy areas of the site remains high, especially if aided by soil surface disturbance.

Figure 16 shows the heaviest infestations of Sahara mustard on the site. Although it generally invades sandy areas, the surveyors noticed that it is most abundant along the shallow margins and skirts of the major dune systems on the west portion of the Study Area. It also dominates shallow sand sheets elsewhere, as well as certain sand accumulations adjacent to abandoned agriculture fields.

Figure 16

Sahara Mustard
(Brassica tournefortii)
Distribution

AR060530

It should be noted that Sahara mustard had very little presence on the disturbed and abandoned agriculture fields in the center of the site. This goes against the common association of disturbed areas becoming breeding grounds for weeds. In fact, both of the main agricultural fields seemed to support very few invasive weeds at all.

Control of Sahara mustard remains a challenge. It has become so widespread across southern California deserts in the last 20 years and so aggressive that control seems ineffective. Avoidance of disturbance seems the most prudent approach, but it still thrives on undisturbed areas. An Integrated Weed Plan will be designed to prevent, as much as possible, the further spread of this weed.

Russian Thistle (*Salsola tragus*) was observed mostly on the gen-tie line sand dune areas, with occasional small occurrences across disturbed areas of the site. This plant represents the second most common weed onsite after Sahara mustard. Occasional locally abundant populations are to be expected associated with soil disturbance and loose sand. Russian thistle is known to thrive on disturbed soil, so monitoring and control measures will need to be incorporated into the Integrated Weed Plan.

Mediterranean grass (*Schismus barbatus*) is widespread across the site in many habitats but never "abundant." This plant is so widespread across many California deserts that it has become the dominant annual grass in many situations. Although it is very common, it poses only a slight ecological type conversion risk in this locally harsh situation. No control is proposed.

Bermuda grass (*Cynodon dactylon*) was observed in the Desert Dry Wash Woodland along the northern part of the site adjacent to the solar farm. Two small patches were seen growing in the shade of ironwoods. They were in robust condition, flowering and fruiting. Bermuda grass' potential to spread is moderate to high, but would be limited by habitat preferences of reliably moist soil and shade.

Puncture vine (*Tribulus terrestris*) was observed on disturbed areas on the borders of the abandoned jojoba farm near the center of the site. Only a couple of individuals were seen, and its potential to become invasive and widespread is low.

Lamb's quarters (*Chenopodium album*) was seen with only a few scattered occurrences on the main solar site. Its potential for invasiveness and ecological damage is low.

Nettleleaf goosefoot (*Chenopodium murale*) was seen with only a few scattered occurrences on the main solar site. A common agriculture weed, its potential for invasiveness and ecological damage is low.

Prostrate knotweed (*Polygonum aviculare subsp. depressum*) is a common agricultural and ruderal weed. It was seen only once during spring surveys, and is not considered a major invasive threat.

Eucalyptus (*Eucalyptus* sp.) occurs only as a couple of planted individuals on the north margin of the site

on the border of the existing solar facility. Its potential for invasiveness is low due to the harsh conditions of the local landscape.

Tamarisk (*Tamarix ramosissima*) occurs as only a couple of dwarfed individuals on the north margin of the site at the border of the existing solar farm. It has a moderate potential to expand but would be limited by the lack of reliable water nearby. It should be removed promptly, in any case.

3.2 RAINFALL ANALYSIS

Available historical winter rainfall data from the Blythe CAA Airport was summarized to obtain a useful average for the Blythe area (Table 7 and 8). The historical average monthly rainfall for the Blythe area was estimated to be 0.30 inches and 0.37 for 2012.

Table 7 Historical Winter Rainfall Data (inches)[1]

	October	November	December	January	February	March	Annual Total	Monthly Average
Blythe CAA Airport[1]	0.26	0.19	0.41	0.48	0.44	0.35	3.55	0.30

[1] Western Regional Climate Center (2013)

Table 8 Rainfall 2012 and 2013 (inches)[1]

Blythe CAA Airport[1]	0.27	0.00	0.86	0.77	0.01	0.03	4.47	0.37

[1] Western Regional Climate Center (2013)

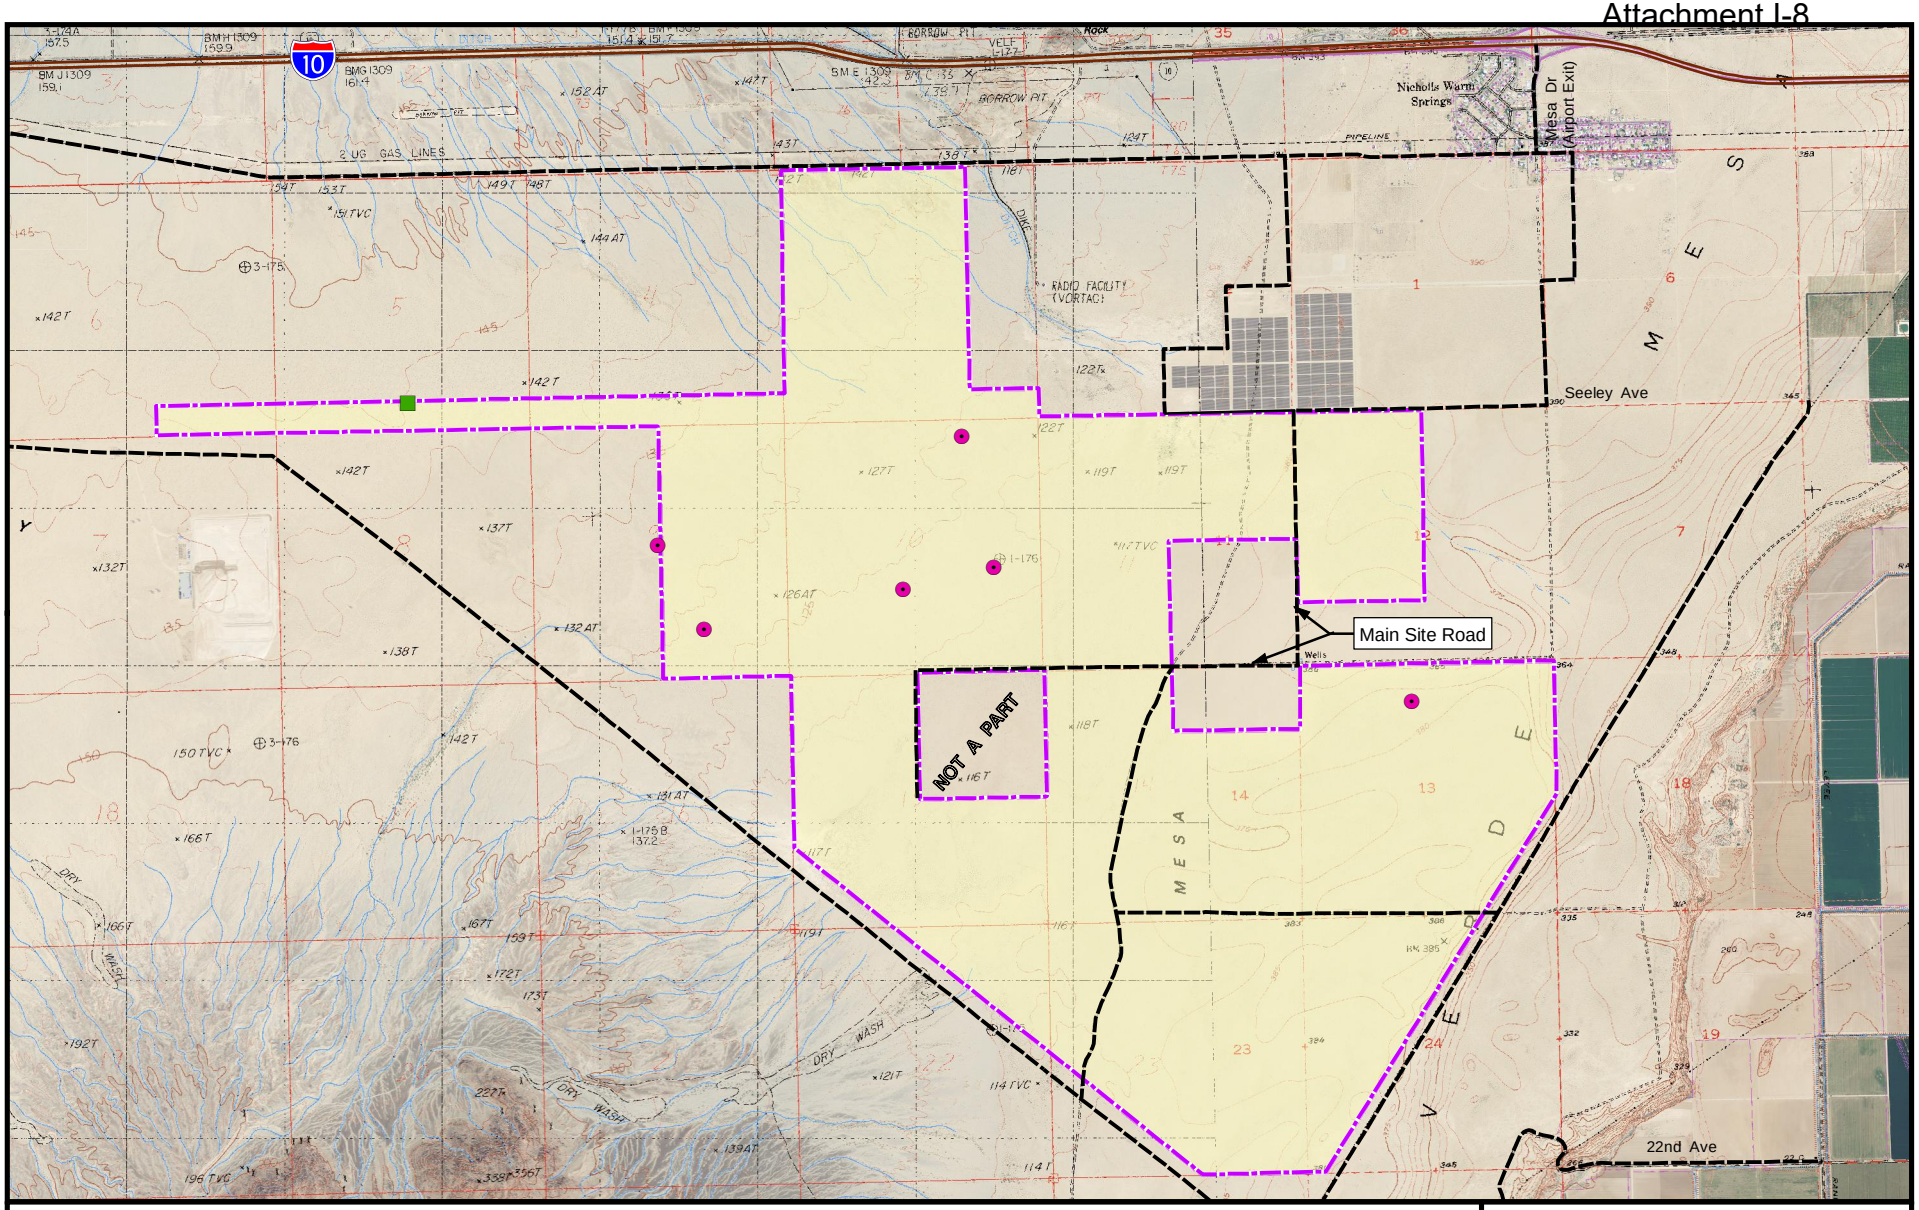
3.3 AMPHIBIANS

Overall, there were 27 different points that were identified as having standing water at some time on the Project site (Figure 5). Of these spots, two were identified as the most likely to support Couch's spadefoot in the event of rains as they were not only the most extant areas for having held water, but because they also exhibited a strong component of dry desert wash woodland plant species.

3.4 REPTILES

3.4.1 Desert Tortoise

Desert tortoise (*Gopherus agassizii*) is a federal and state listed threatened species. Desert tortoises are well adapted to living in a highly variable, and often harsh, desert environment. They spend much of their lives in burrows, even during their seasons of activity. In late winter or early spring, desert tortoises



emerge from over-wintering burrows and typically remain active through fall. Activity does decrease in summer, but tortoises often emerge after summer rain storms. Activity and movement is generally influenced by temperature and precipitation, which correlate with potential food and water resources. Extreme temperatures, both high and low, and periods of drought typically result in reduced tortoise activity (Franks et. al. 2011). Mating occurs both during spring and fall. Tortoises are long-lived and grow slowly, requiring 13 to 20 years to reach sexual maturity [at approximately 180 millimeters (mm) mean carapace length (MCL)]. Eggs are generally laid in friable soil at near burrow entrances between April and June and occasionally September and October. Eggs hatch within three to four months.
Soils must be appropriately soft for digging burrows, but firm enough so that burrows do not collapse. Tortoises typically prefer habitats with abundant annual forbs, grasses and cactus, which constitute its primary food sources.

Desert tortoises occupy home ranges, which are generally defined as the area traversed while carrying out a range of normal activities (e.g., foraging and mating). The size of desert tortoise home ranges can vary with respect to sex, geographic location, substrate, topography, and year depending on climate factors such as rainfall and temperature.

2013 Results

Desert tortoise sign (i.e., live tortoises, active burrows/pallets, and recent scat, and tracks) found in the Study Area were six disarticulated carcasses and a set of tracks (Figure 17). All carcasses were disarticulated and over four years of age. No desert tortoise burrows were detected. A set of tracks was found by Alice Karl, PhD. during the botany surveys on March 22, 2013 traveling north across the dunes. Although the entire Study Area could be considered tortoise habitat, few tortoises would be expected in most of the site because of the poor cover both in and out of the washes and such low species richness and stature that the forage base may be similarly under-developed.

3.4.2 Mojave Fringe-Toed Lizard and Herpetofaunal

Overall, 3,483 different individual squamates were observed over the span of all surveys undertaken (Table 9), with 98 percent of those sightings lizards. Of the lizard composition, ten different species were recorded with five species totaling over 95 percent of the total animals observed (Table 9). Western whiptail (*Aspidoscelis tigris*) was the most common lizard observed on the site with large numbers of common side-blotched lizard (*Uta stansburiana),* zebra-tailed lizard *(Callisaurus draconoides),* desert iguana *(Dipsosaurus dorsalis),* and Mojave fringe-toed lizard (*Uma scoparia)* was also observed. Six different species of snakes were encountered within the survey period with the majority comprised of the majority comprised of the species sidewinder rattlesnake (*Crotalus cerastes*) (Table 10). Due to the type of sampling methodology, the majority of observations were comprised of diurnal or day active, wide-ranging, foraging squamates.

Using species maps for Southern California squamates, there could be as many as two different California Species of Concern present upon the proposed Project site. These two species were the Mojave fringe-toed lizard and Colorado Desert fringe-toed lizard (*Uma notata*). To determine the extent of their presence on the site, waypoints were taken by survey crews upon encountering these species during all surveys (Figure 18).

Overall, members of the Uma species made up seven percent of the total squamates seen by species (Table 9). These individuals were confined to the fine sand or the sandy loam areas that occupy the northwest corner and the gen-tie area of the Project site (Figure 18). After identifying lizards as members of this genus, 13 individuals (five male and eight females) were collected briefly to identify them down to species level. According to Stebbins (2012), a good method to do this is according to inter- naris scale patterns, where the Mojave will have five scales in a pattern across the snout and the Colorado Desert fringe-toed exhibits a scale pattern of three. All individuals that were scrutinized were identified as Mojave and not Colorado Desert individuals using this method (Photograph 10).

3.5 AVIAN

3.5.1 Migratory Bird Surveys

3.5.1.1 Unlimited Distance Extended Observation Surveys

Each migration point was visited eight times between April 18th 2013 and May 30th 2013 (Table 11). The number of visits was limited during the spring migration period due to delays surrounding agency acceptance of a project-specific Avian Work Plan. However, it is anticipated that scheduled migration surveys in spring 2014 will provide sufficient additional data points to adequately illuminate a final report and/or BBCS.

Table 11.Migration Point Visits-Spring 2013

During the spring 2013, 97 birds were detected during 80 hours of observation (16 visits). The average number of birds detected per hour was 1.2125, this number includes five visits without any detections. Past research has shown that the peak of migration within this area occurs on April 22nd (McCrary et. al, 1982), Table 12 shows a peak in the number of birds detected on April 18th, 2013.

3.5.1.2 Line Transect Sampling

Line Transect Data will be analyzed by a qualified statistician, prior to the development of a BBCS. These data will inform an Avian Risk Analysis associated with the BBCS. Appendix G contains a species list that was compiled over the course of all survey efforts during the spring 2013. Table 14 below summaries the survey time, date and surveyor of each line transect.

Table 14. Summary of Line Transect Surveys Conducted 18 April Through 20 May 2013

3.5.1.3 Western Burrowing Owl

During fall 2012 and spring 2013, 24 burrowing owl burrows within the Project site ranked Class I, Class II or Class III. An occupied burrow was detected incidentally during general avian survey efforts on May 13, 2013. This incidental detection involved a pair of owls utilizing a previously unoccupied rodent burrow. An additional burrow with indications of recent burrowing owl occupation was recorded during surveys of the 150 m buffer (Table 15 and Figure 19).

Phase III Burrowing Owl Survey Results

Observers recorded each burrow's current status and condition, and visually searched the surrounding area for live owls (Appendix H). Each of the 26 locations was visited during the intervals; 22-30 May, 19-22 June and 12-16 July.

Phase II initial surveys documented live owls at three burrows prior to breeding season surveys. All three of these burrows were determined to be vacant when Phase III surveys were conducted (Table 16).

Table 16. Determination of Burrows Occupied by Burrowing Owls Prior to Breeding Season

Waypoint ID	Phase II Survey Date	Phase II burrow classification	Phase III Survey Date	Phase III burrow classification
CVS153	21 Oct 2012	1	18 May2013	4
PHK646	22 Oct 2012	1	27 May 2013	4
PHK647	22 Oct 2012	1	27 May 2013	4

CVS153 was collapsed and no longer serviceable without re-excavation. PHK646 was an active kit fox (*Vulpes macrotis*) den, and PHK647 appeared to have been re-excavated and potentially occupied by coyote (*Canis latrans*).

Phase III surveys documented live owls at two burrows. One of these burrows was potentially occupied during Phase II surveys (Class 2); the other is believed to have been a previously undocumented rodent burrow (Table 17).

Table 17.Burrows Occupied During Breeding Season

Waypoint ID	Phase II Survey	Phase II burrow classification	Phase III Survey	Phase III burrow classification
RR0002	N.A.	N.A.	13 May 2013	1
PHK837	9 Apr 2013	2	24 May 2013	1

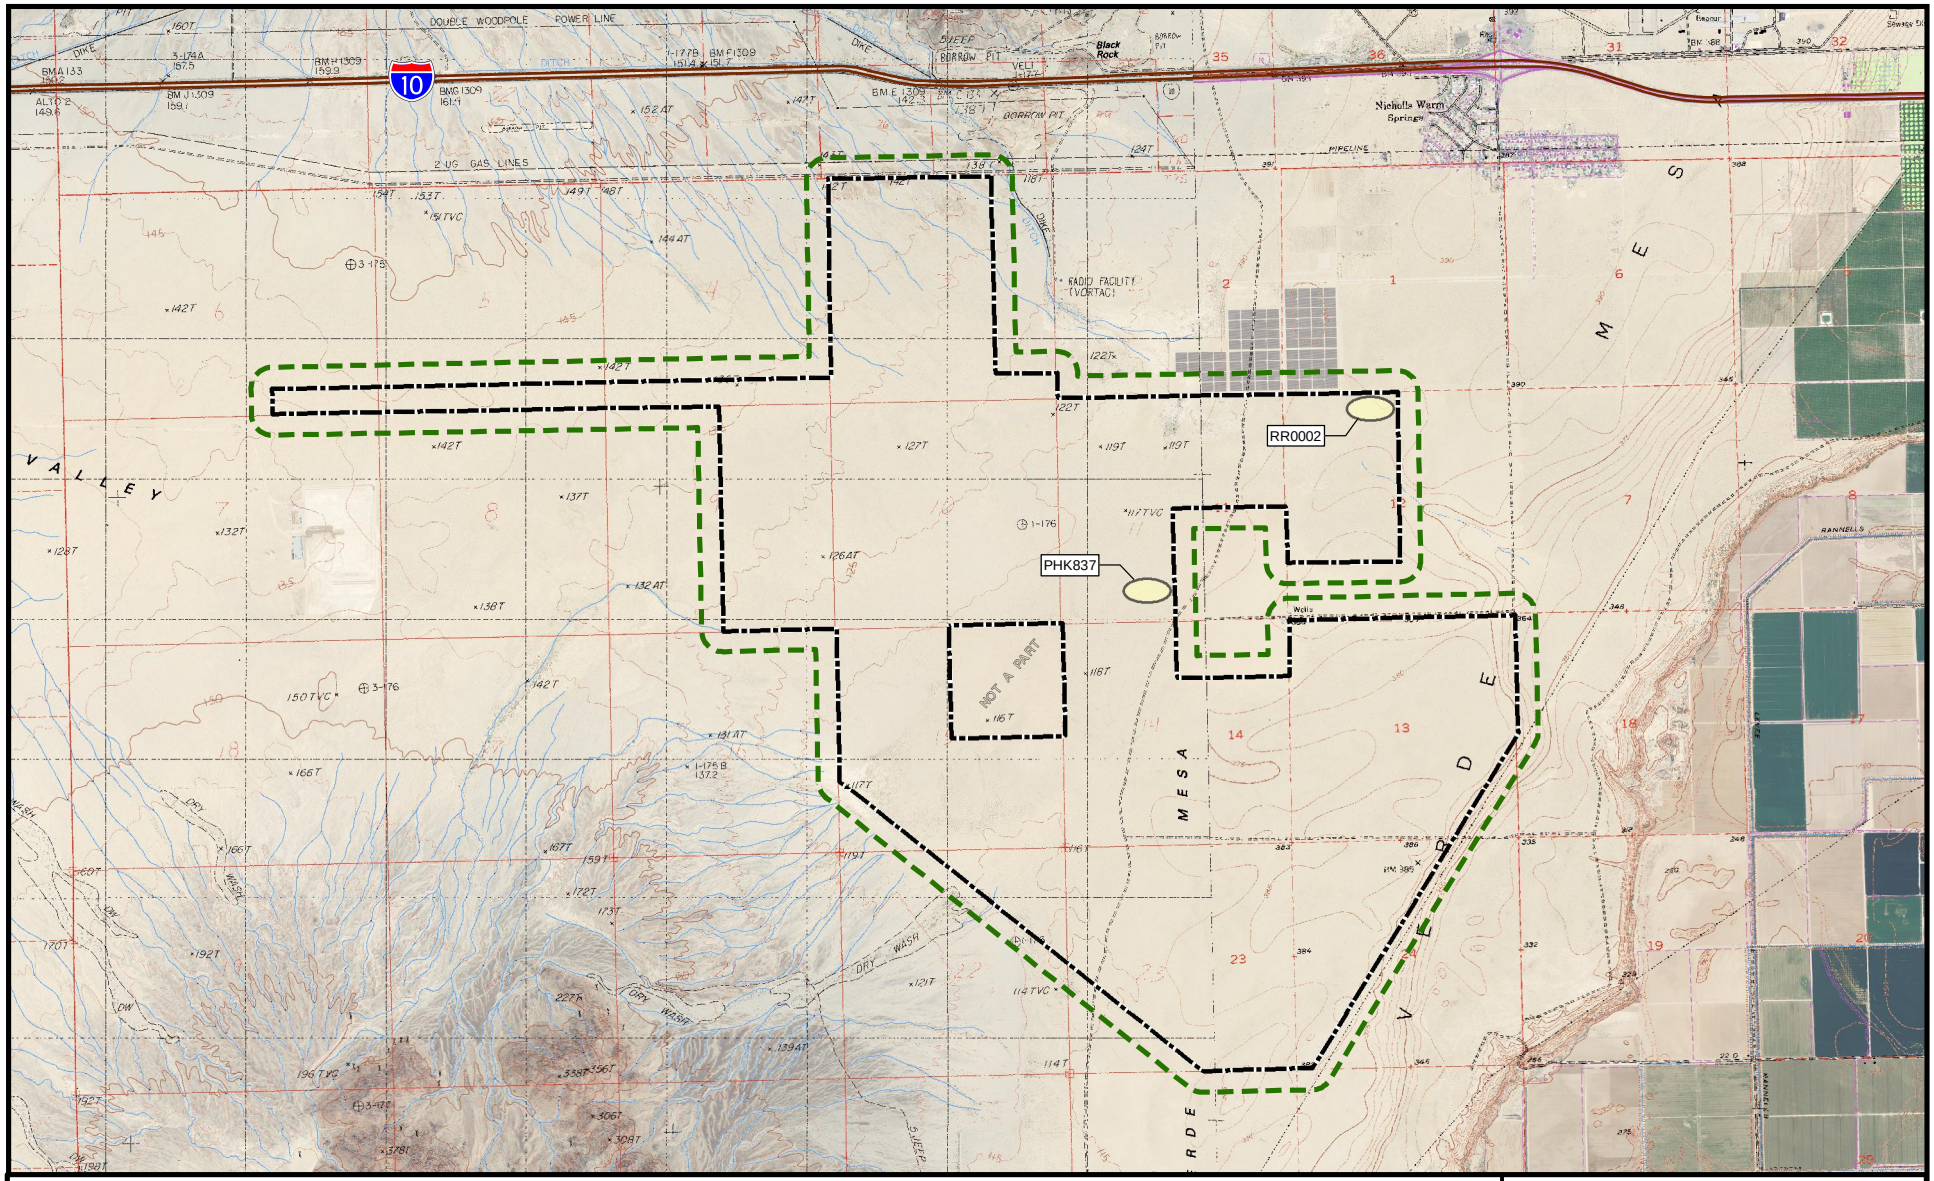
Burrowing owls occupying burrows during the breeding season were monitored in an attempt to determine territorial boundaries and home ranges (Figure 20).

Observations of the burrowing owl pair at RR0002, suggested dependent young were in the burrow on 15 July, although no non-adults were directly observed during a total of more than 15 hours of observation. Observations of the burrowing owl pair at PHK837 (burrow apparently re-excavated), suggested the

breeding attempt was abbreviated by a potential nest predator as the burrow was abandoned between 20 June when a pair was present, and 14 July when no owls were detected. No young-of-year were ever observed at this burrow and adults were not detected away from the burrow on a subsequent follow-up search on 15 July.

3.5.1.4 Golden Eagle Surveys

Agency approval of the Quartzite Avian Work Plan was not granted until after the 2013 Golden Eagle breeding season ended. Golden Eagle surveys will be performed between 1 December 2013 and 31 May 2014 in order to determine territory occupancy and productivity within 10 miles of the project boundary.
No potential golden eagle nesting habitat or active territories exist within the proposed project footprint. Potential golden eagle nesting habitat exists within 10 miles of the Project site boundary; in the Little Chuckwalla Mountains, the Mule Mountains and the McCoy Mountains.



There have not been golden eagle detections during avian-focused surveys, including Avian Point Counts, Unlimited Distance Extended Observation Surveys and Line Transect surveys. There have been no reports of incidental sightings of golden eagles, which would have been reported on standardized, "General Sensitive Species" data forms that are included as required reporting for all of the various biological resource disciplines.

3.5.1.5 Elf Owl Surveys

Most of the project site and the adjoining buffer zone is comprised of scrubland dominated by creosote bush (*Larrea tridentata*), and is therefore completely unsuitable for use by elf owls.
A small patch of microphyll woodland (Lower Colorado subdivision of Sonoran desert scrub) of less than one hectare (11 S 0708580 3718750) occurs immediately south of the present solar facility and contains widely scattered ironwood, and blue palo verde trees plus several nonnative trees.

A drainage from McCoy Mountains runs north (11 S 0706925 3720960) to south (11 S 0707924 3719323). Most (97 percent) of the wash is within the one mile project buffer zone, but it also transects the most northeasterly corner of the Project site. This wash contains approximately 10 hectares of microphyll woodland with scattered ironwood and palo verde trees. It is between 30 to 70 m wide with trees spaced 15 to 60 m apart, and 7 to 9 m tall.

There are a series of braided drainages along the southwestern boundary of the project site running west to east from the foothills of the Mule Mountains. The largest drainage contains approximately 16 hectares of scattered ironwood and palo verde trees, and runs 1.6 km west (11 S 0705570 3714515) to east (11 S 0707065 3715170) across the buffer zone and ends at the powerline road. The patch is between 50-150 m wide with trees spaced 5-30 m apart, 5-8 m tall, with an open canopy and little understory.

Figure 20

Observed BUOW Territories During Breeding Season

P:\GIS\Ironwood\Desert_Quartzite\BUOW_20130620.mxd

AR060547

Scattered patches of honey mesquite occur on the slope between the upland desert scrub of the Palo Verde Mesa and the lower Colorado River floodplain, which contains extensive farmland. Mesquite trees growing along this slope were 3 to 5 m tall and found in thickets 20 to 40 m wide. There were no large trees, e.g., cottonwood (*Populus fremontii*), associated with these areas.

Assessments were made for two nearby areas that fell outside of the one-mile project buffer zone.
The Mesa Verde housing area was assessed because it superficially resembles certain trailer parks or campgrounds along the lower Colorado River where Elf Owls have been detected. It consists of trailers and small homes with yards containing native trees including palo verde, mesquite (*Prosopis* sp.), saguaro cactus (*Carnegiea gigantea,* a total of eight individuals) and nonnative columnar cacti and trees including eucalyptus, palms, African sumac (*Rhus lancea*), and pines (*Pinus* sp.). However, no cavities were observed in this area and no cottonwood trees were present.

An area of microphyll woodland north of and adjacent to the I-10 freeway corridor located along Black Rock Road was assessed. This woodland patch is approximately 1.5 km long and 30-100 m wide (about 12 hectares). This area contains palo verde and widely scattered ironwood (7-11 m tall) and is generally located between a gas station and the truck stop facilities (east end, 11 S 0710795 3721265) and a weigh station (west end, 11 S 0709305 3721290). The woodland is crossed by numerous roads and contains several disturbed areas. Trees also occur on the south side and the center strip of the freeway.

In the surveyors' judgment, none of the habitat patches assessed and discussed above met minimal standards as elf owl nesting habitat. For most patches, this lack of potential was a function of inadequate tree density and/or cavity density, combined with inadequate or marginal patch size. The mesquite patches observed within the buffer zone are much less suitable in terms of patch size and tree density than the mesquite patches within which elf owls sometimes occur along the lower Colorado River. The most promising area for elf owls that was observed occurred outside the buffer zone and adjacent to the interstate, where there were some areas of large, closely spaced palo verde trees, but even here, surveyors determined that potential for elf owls is very low, and mitigated against further by proximity of multiple disturbances, including the interstate highway itself.

3.5.1.6 Nesting Raptor/Raven Surveys

Nesting raptor/ Raven surveys were conducted monthly between May 1 and June 1, 2013. This effort focused on the detection of all raptor/raven nests within one mile of the Project site in order to collect baseline data for the following:

- The number and distribution of raptor/raven nests prior to project development; and
- Success rates of raptor/raven nests prior to project development.

All bird nests (including the incidental detection of resident passerine species) were recorded on standardized datasheets. Monthly monitoring efforts were completed to update the datasheets to include the development stage and breeding status at each raptor/raven nest.

3.6 MAMMALS

3.6.1 Small Mammal Surveys

Results are summarized in Table 19. Pocket mouse (*Chaetodipus)* species were lumped due to unreliability of field identification between long-tailed and desert pocket mouse (*C. formosus* and *C. penicillatus)*. In total, seven species were found at the baseline points.

Table 19 Baseline Points: Small Mammals, April 2013

3.6.2 Desert Kit Foxes

Desert kit fox is protected by the California Code of Regulations (Title 14, CCR: §460) and Fish and Wildlife Commission Section 4000 as a fur-bearing mammal. Desert kit foxes are fossorial mammals that occur in arid open areas, shrub grassland, and desert ecosystems. Desert kit fox typically consume small rodents, primarily kangaroo rats, rabbits, lizards, insects, and in some cases immature desert tortoises. Dens typically support multiple entrances, but desert kit fox may utilize single burrows for temporary shelter.

Litters of one to seven young are typically born in February through April (Egoscue 1962; McGrew 1979). This species was detected within the Study Area. Full-coverage burrow surveys revealed 46 canid complexes and 45 single-entrance dens (91 potentially occupied dens/complexes) with some kit fox sign within the Project site. Only 24 of those had signs of recent activity, (i.e., desert kit fox tracks, or scat).

Each of these was revisited by an experienced mammal biologist for further inspection of signs of activity. Upon re-inspection, eight dens/complexes were determined to be potentially active, all of which were in the southern portion of the Project site (Figure 21). A camera station was set up at each of the eight dens and run for three consecutive days and nights (Photograph 11). Six of the eight cameras captured images of nine total individual desert kit fox as follows (Table 20):

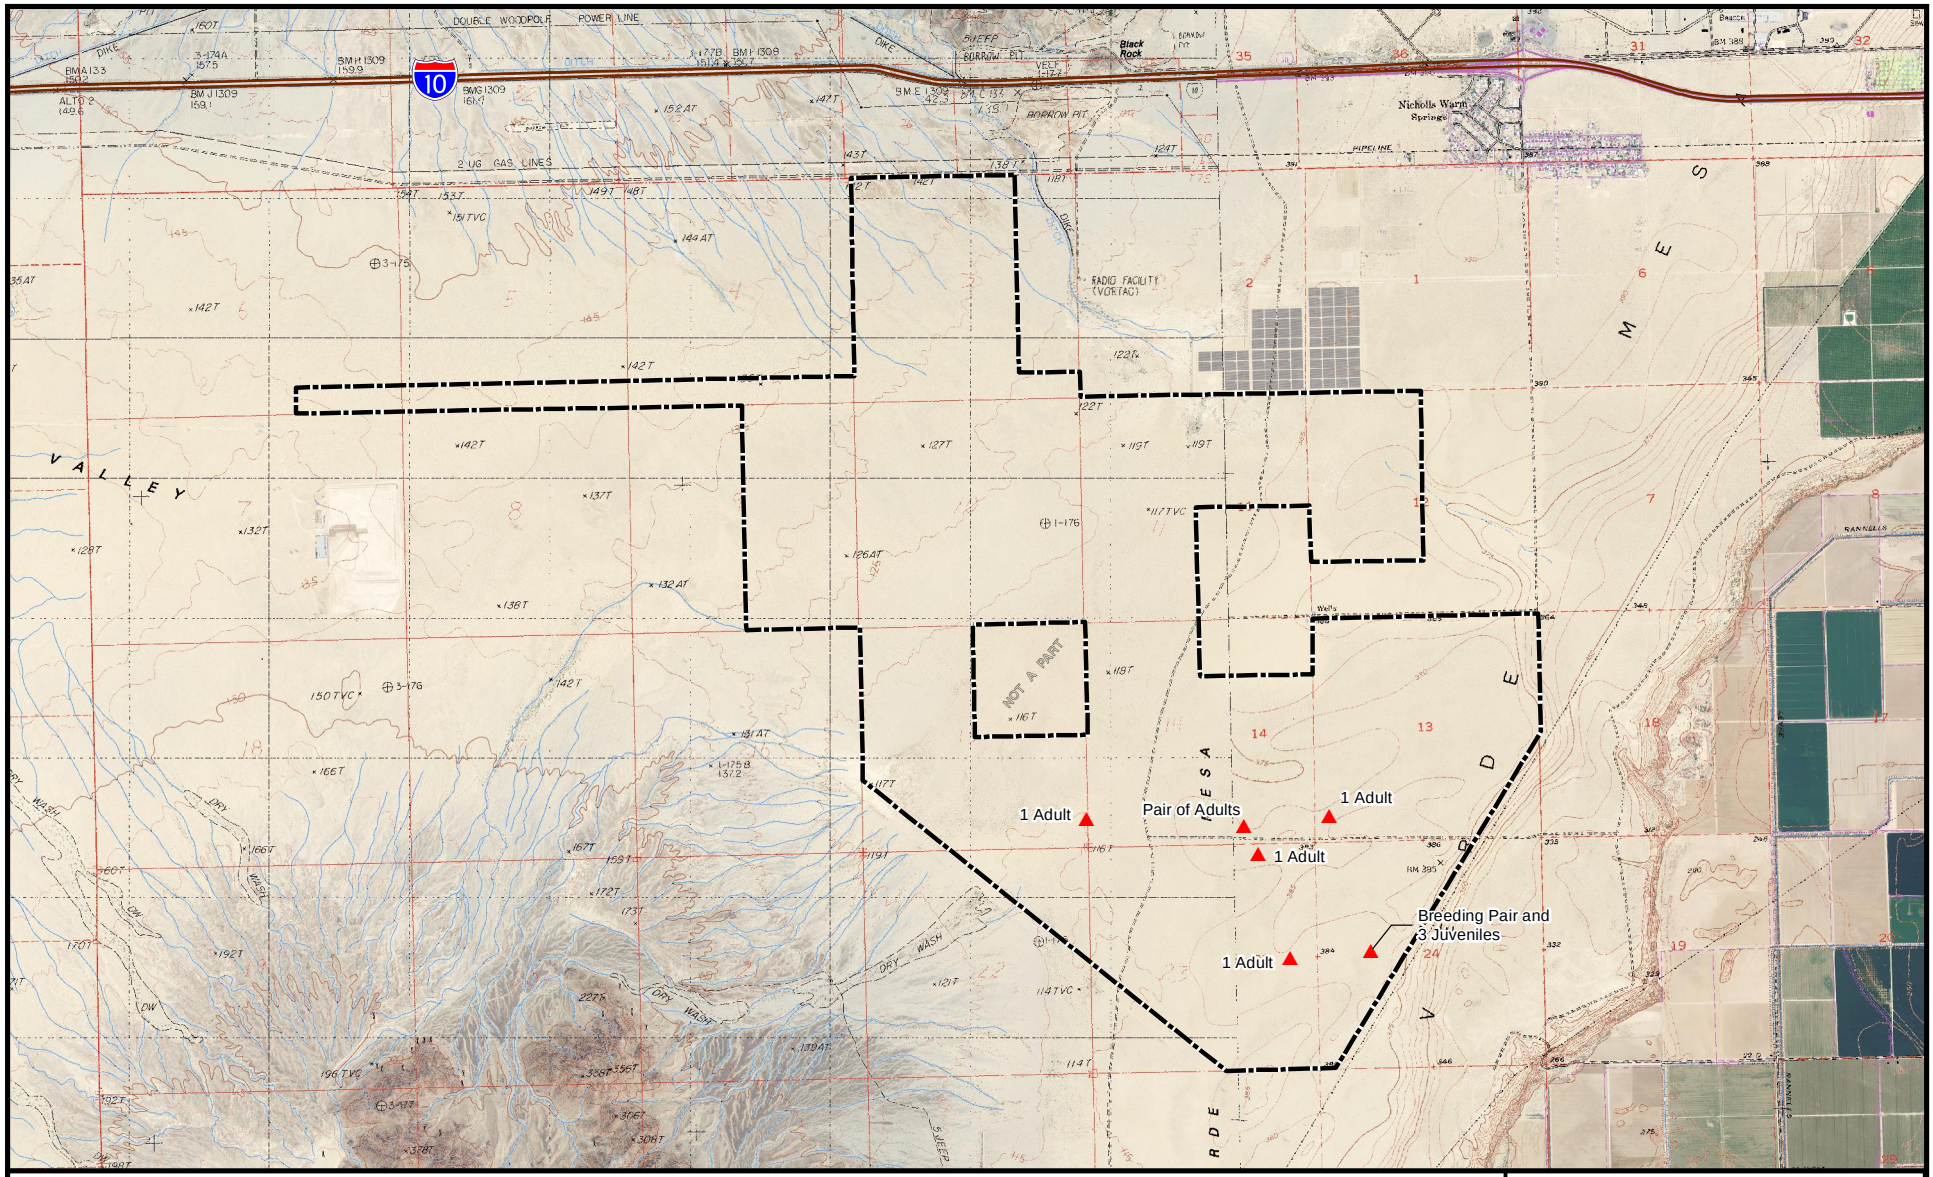

Table 20.Desert Kit Fox Presence, April 2013

Den Location UTM WGS84	Number of Individuals Photographed	Dates
11 S 707745 3715760	1 Adult	April 29- May 1, 2013.

11 S 709479 3715780	1 Adult	April 29- May 1, 2013.

3.6.3 Bats

Roost surveys were conducted of mines in the mountains adjacent to the project area during the day and at night for evidence of bats and guano. Two mines in the southern McCoy Mountains (located approximately 4.4 miles northwest of the Study Area) had previously been identified by Dr. Brown as California leaf-nosed bat maternity colonies and had been gated with bat compatible closures by the Bureau of Land Management in 2011. These mines were monitored on May 8 at dusk by surveyors with night vision equipment to obtain accurate exit and entry counts of bats and acoustic records with additional Anabat detectors. The surveyors kept two counts for at least sixty minutes after the first bat exited of how many bats entered and exited the mines. Video cameras with auxiliary infrared lights were used to remotely monitor mines and to obtain permanent records of exiting bats. During the current survey, pallid bats were observed and recorded at the mines in addition to California leaf-nosed bats. The size and flight pattern of the two species are similar, but the echolocation and social calls are distinctive. The Uvanum Mine (33.64064,-114.82957) is closest to the Study Area, and 33 bats exited and 26 entered the mine in the hour after dark. To the west in another canyon, 71 bats exited and 44 entered the McCoy #3. Non-resident bats may enter a mine to “night-roost”, so the exiting and entering bats may not be the same individuals or species.

Using topographic maps and Google Earth images, ground reconnaissance was conducted of possible mine features on the north end of the Mule Mountains (1.8 miles south of the Study Area) and no underground features that could shelter bats were discovered.

Photograph 11 - Desert Kit Fox Family Captured on Camera on Project Site, April 29, 2013.

The closest known bat colony in the Mule Mountains is the Hodge Mine (a.k.a. Stonehouse, 33.51145,-114.79383) situated 3.4 miles south of the Study Area. This mine contains the largest winter colony of California leaf-nosed bats (*Macrotus californicus*) in the United States, as well as a maternity colony. It is also one of four maternity colonies for the cave myotis (*Myotis velifer*) in California. This mine has been a research site for Dr. Brown since 1976. On the evening of May 9, a net count of 3,348 bats exited from the five portals of the Stonehouse Mine.

Bat Species

Six bat species are interpreted as detected acoustically within the Study Area (Table 21). Seven of these (pallid bat, canyon bat, California and cave myotis, Mexican and pocketed freetail bat and Western mastiff bat) yielded multiple diagnostic call sequences. For 50 kHz Myotis sequences (calls ending at this frequency) two species (*Myotis californicus* and *Myotis yumanensis*) are often not distinguishable. California myotis is far more common in open desert habitats distant from surface water, and we interpret these call sequences as this species. A small sample of 40 kHz Myotis call sequences was obtained at four monitors. There are two *Myotis* in this area that produce similar calls at this frequency, but, given the low likelihood of occurrence of the other species and the proximity to occupied cave myotis (*Myotis velifer)* roosts, surveyors conclude that these sequences represent that species. Seven additional species have the potential to occur at some time of the year (Table 21). The most likely is the California leaf-nosed bat that roosts close to the Study Area, and can hunt without emitting echolocation signals, relying solely on vision and prey-produced sounds. Four of the acoustically detected species are California State Species of Special Concern: pallid bat (*Antrozous pallidus*), cave myotis, Western mastiff bat *(Eumops perotis*) and pocketed free-tailed bat (*Nyctinomops femorosaccus*).

Table 22 shows acoustic activity by site and night for species and one sonotype or frequency category. Q25 groups non-diagnostic calls from larger mid-frequency bats (19-35 kHz) and is included to show relative activity among sites. Values in the table are counts of minutes per night with activity by a species (Miller 2001). Canyon bats (*Parastrellus hesperus*) and 50 kHz California myotis (*Myotis californicus*) were the most common species detected during echolocation surveys. Over this short sampling interval, higher bat activity (especially pallid bats) occurred at sites with more extensive woody vegetation, notably in the wash immediately east of the project north boundary (Site 4), and south of the existing solar installation (Sites 5 &6. Lower activity was detected at sites with scattered creosote bush and few or no trees (e.g., site 7).

Table 21.Bats Potentially Occurring Near the Project Site

3.6.4 Other Species Noted During Surveys

During various flora and fauna surveys, sign of general species were noted. A species list of general species detected on the site is in Appendix B. American badger (*Taxidea taxus*) was the only additional species of concern associated with the project.

American badger is a State Species of Special Concern associated with open grassland and desert communities. This species is associated with dry open forest, shrub, and grassland communities with an adequate burrowing rodent population; therefore, this species has high potential to occur within the Study Area. Several badger digs and scat were found on the Study Area, mostly near the southwestern perimeter. This species was not directly observed during the focused surveys or on imagery from camera stations around the site.

4.0 RECOMMENDED PROTECTION MEASURES

The following information is intended to provide the California Environmental Quality Act (CEQA)/National Environmental Policy Act (NEPA) document preparers an outline for general avoidance and minimization measures potentially relevant to the Desert Quartzite Solar Project. The following measures are considered standard practices for large-scale utility projects and are consistent with the *Best Management Practices and Guidance Manual: Desert Renewable Energy Projects* (Renewable Energy Action Team 2010). Due to the initial stage of the project and thus the lack of specific design and construction details, the following recommendations are non-specific and should be modified, as needed, as the project progresses.

4.1 GENERAL MEASURES

This section describes a range of design features, construction and operation best management practices (BMPs), and avoidance practices that when implemented as part of Project construction and/or operation, should collectively avoid, reduce or eliminate potential adverse effects to biological resources. Each category of features, practices and plans is described separately below.

Environmental Inspection and Compliance Monitoring Program and Plan

A comprehensive Environmental Inspection and Compliance Monitoring Program and Plan, covering both construction and operation and maintenance (O&M), should be developed. A qualified individual should be designated to serve as the Project Environmental Manager. The Environmental Manager should be responsible for the following tasks.

- Development and implementation of the overall Project compliance program;
- Communication and coordination with the applicable regulatory agencies;
- Ensuring compliance with the various conditions and requirements of permits and approvals;
- Record keeping and reporting required by permits and approvals;
- Ensuring that all applicable environmental plans are up to date;
- Advising management of actual and potential compliance issues; and
- Ensuring that Project planning takes appropriate account of compliance issues in advance.

Construction Related Plans

The following construction-related plans should be developed, as necessary. These plans have specific objectives that would indirectly help reduce potential adverse effects to biological resources.

- Storm Water Pollution Prevention Plan;
- Dust Control Plan;
- Waste Management Plan;
- Spill Prevention Control and Countermeasure Plan;
- Hazardous Materials Management Plan; and

- Fire Prevention Plan.

Construction-Related BMPs

The following general measures should be implemented during construction, which would assist with reducing potential adverse effects to biological resources,

- Construction and O&M activities should be limited to daylight hours to the extent possible;
- Water required for construction purposes should only be stored in closed containers or structures and should be transported throughout the site in enclosed water trucks;
- Water sources (such as wells) should be checked periodically by monitors to ensure they are not creating open water sources through leaking or consistently overfilling trucks;
- All vehicles leaking fuel or other liquids should be immediately removed to the staging area and repaired – all spills should be cleaned up promptly and disposed of correctly;
- All construction activities conducted outside the fenced areas should be monitored by a qualified biological monitor;
- Vegetation removal should be limited to the smallest area necessary;
- Construction traffic should remain on existing roads when possible – new roads, passing areas, and turning areas should be limited to permitted area of direct effect;
- Speed limits on all unpaved areas of the Project site should be a maximum of 15 miles per hour;
- Trash should always be contained within raven-proof receptacles and removed from the site frequently, including trash collected in vehicles in the field;
- No dogs or firearms should be allowed on the Project site during construction or O&M; and
- Plant and wildlife collection by Project staff during construction or operation should be prohibited except as allowed by the Project's permits.

Worker Environmental Awareness Program

A formal Worker Environmental Awareness Program (WEAP) should be completed for every individual working on the Project site. All individuals completing the training should sign an attendance sheet and receive wallet cards and stickers to show they have completed this training. The training should include the photographs of all environmental resources and the following information:

- Discussion of the fragile desert ecosystem, vegetation and wildlife communities within and surrounding the Project site;
- Discussion of rare plant species and other sensitive species found within and surrounding the Project site;
- Desert tortoise ecology, threats, legal protections, permitting, and penalties (including both legal and imposed by Project permits);
- Project-specific protection measures for species;
- Any safety measures personnel should be aware of as it relates to the species or environment on the Project site; and

- Worker responsibilities, communication protocol, and monitor responsibilities, including the authority for monitors to halt Project activities if warranted.

4.2 BOTANICAL STUDY

4.2.1 Special Status Plant Species

The Vegetation Resources Management Plan (VRMP) will provide details regarding the proposed salvage and transplantation of target species; the VRMP will include the following,

- Distribution of target plants within the Project site;
- Criteria for determining whether an individual plant is appropriate for salvage;
- Equipment and methods for salvage, propagation, transport, and planting;
- Procedures for marking and flagging target plants during preconstruction clearances surveys;
- Storage and/or pre-planting requirements;
- Proposed transplantation sites;
- A requirement for ten years of maintenance of the transplanted individuals, including removal of invasive species and irrigation (if necessary); and
- A requirement for ten years of monitoring to determine the percentage of surviving plants each year and to adjust maintenance activities using an adaptive management approach.

4.2.2 Cactus and Yucca

Cactus and yucca found onsite could be relocated to a nursery for future restoration areas or relocated if adjacent land was purchased for mitigation, these actions would be covered in the VRMP.

4.2.3 Desert Dry Wash Woodland and Vegetation Communities

Desert dry wash woodland is considered sensitive by the California Resources Agency and BLM due its limited distribution, value to wildlife, and susceptibility to disturbance (BLM 2002 and Zeiner, et al., 1990). The presence of water at least on a seasonal flow regime is vital for this community to persist. Due to this fact, and that the community covers very little of the project area, project boundaries could be adjusted to avoid impacts the desert dry wash woodland and add a distance buffer between this vegetation community and the project area.

4.2.4 Non-Native and Invasive Species

An Integrated Weed Management Plan (IWMP) should be prepared to reduce and/or eliminate the propagation and further spread of noxious and invasive weeds within and outside the project area due to

construction, operation and decommissioning of the Project. The objectives of the IWMP would be as follows.

- Identify weed species currently present within the Project components;
- Identify weeds not seen on the Project components that may have the potential to be present in the Project area and have the potential to invade the Project site due to construction activities;
- Identify construction and maintenance activities that may increase the presence of weeds or introduce new weed species on and adjacent to the Project components; and
- Specify steps that should be taken to ensure that the presence of weed populations on and adjacent to the Project components should not increase because of construction activities. These steps should be intended to prevent weeds not currently found on the Project site from becoming established there, and prevent weeds already present on the site from spreading to other areas.

4.3 AMPHIBIANS

There has been an on-going effort since 2008 to check the project site after heavy rains to search for ponding water that sustains itself for eight days, which is what is required for the reproduction of spade foot toads. No areas have held water for eight days. It is recommended that Project site be surveyed for ponding after heavy rains until construction.

4.4 REPTILES

4.4.1 Desert Tortoise

Due to the potential presence of desert tortoise within the Project site, formal consultation between the BLM and USFWS would be necessary. A biological assessment that fully addresses the impacts to desert tortoise would be required to initiate formal consultation. Additionally, an incidental take permit would be required from the California Department of Fish and Wildlife in compliance with the California Endangered Species Act.

The measures described in this section reflect standard requirements and may be incorporated as part of the proposed Project, which would also be included in the biological assessment. The Biological Opinion (BO) would provide specific conditions and requirements that may supersede some of the following measures. A Lead Biologist should be designated for the Project and should be responsible for all aspects of clearance surveys, monitoring, desert tortoise translocation, contacts with agency personnel, reporting, and long-term monitoring and reporting.

Exclusion Fencing

Prior to beginning clearance surveys, desert tortoise exclusion fencing should be constructed in specified areas consistent with clearance survey areas. The Project site should be completely fenced with security and desert tortoise exclusion fencing, including desert tortoise exclusion gates at access points. Fence installation should be monitored as a linear component. Exclusion fencing should be maintained over the course of construction and operations, as necessary.

Preconstruction Clearance Surveys

Clearance surveys should be conducted consistent with the USFWS Desert Tortoise Field Manual and current translocation guidance (United States Fish and Wildife Service 2009b and 2010c). If a desert tortoise or active burrow is found within a planned area of construction, surveys should stop at that time until the tortoise is translocated in the active season and per the Desert Tortoise Translocation Plan. If two complete passes are completed in a construction area (north-south and east-west) without a desert tortoise being found, construction may commence within that area outside of active season. Fencing should continue to be checked on a daily basis throughout construction.

Translocation

A Desert Tortoise Translocation Plan should be prepared for the Project. The purpose of the plan is to describe the process of translocation, minimize mortality of desert tortoises, and assess the effectiveness of the translocation effort through a long-term monitoring program. Injured tortoises should be transported to a rehabilitation facility approved by the USFWS and CDFW. Tortoises found recently killed should be salvaged and transported to a veterinary pathologist, who is familiar with desert tortoise and approved by the USFWS and CDFW. Procedures for salvaging and transport should generally follow Guidelines for the Field Evaluation of Desert Tortoise Health and Disease (Berry and Christopher 2001). Individuals approved and permitted by the USFWS and CDFW to conduct such assessments should conduct detailed health assessments on all live tortoises following current USFWS guidance. Detailed health assessments should be performed prior to translocation and repeated periodically during long-term monitoring.

Avoidance – Construction

During the construction of linear features (fencing, transmission lines, and access roads), all live tortoises and active burrows should be avoided to the extent possible. All activities should be monitored by qualified biologists. The biological monitor should instruct crews to provide approximately one hour for a live tortoise to leave an active construction area without assistance. If the tortoise does not leave the area on its own, an Authorized Biologist (listed under the BO to handle tortoises) should carefully move the

tortoise out of the construction area and into a translocation area pursuant to the conditions of the BO. Biological monitors should flag an avoidance area approximately 20 m from any active burrow to be avoided and construction activities should continue around this avoidance area while a biologist monitors the burrow. If an active burrow cannot be avoided by construction activities, the burrow should be excavated using protocols in USFWS Desert Tortoise Field Manual (United States Fish and Wildlife Service 2009b).

Avoidance – Operations and Maintenance

During the operation phase of the project, all applicable desert tortoise protection measures identified under construction should be implemented. For example, this may include the need for a biological monitor outside the fenced facility during road, fence and utility maintenance involving ground disturbance, annual WEAP refresher training, actions to take if a tortoise is encountered, etc. Additionally, a biological monitor should be designated and responsible for overseeing compliance with the desert tortoise protection measures. The biological monitor should have a copy of all measures including the BO when work is being conducted on site. The monitor should be on site during all project maintenance activities to ensure compliance with the desert tortoise measures. The monitor should have the authority to halt all non-emergency activities that are in violation of the measures. Work should proceed only after hazards to desert tortoise are removed, the species is no longer at risk, or the individual has been moved from harm's way by an Authorized Biologist. An annual compliance report should be submitted to the BLM annually.

Common Raven Management Plan

A Common Raven Management Plan will be written, see section 4.5.4.

4.4.2 Mojave Fringe-Toed Lizard and Herptofauna

The only listed species found on the project site was the Mojave fringe-toed lizard. This lizard is found in loose-sand habitats and areas that have loose sand deposits. It is recommended to construct the project with trying to avoid loose sand areas as much as possible.

4.5 AVIAN

Due to the potential presence of golden eagle, raptors, and bat species within the Project site, a BBCS should be developed. The goal of the BBCS would be to reduce the potential risks for avian and bat mortality potentially resulting from construction and operation of the Project. The objectives of this plan are as follows:

- Identify baseline conditions for raptor and bat species currently present at the Project components;

- Identify construction and operational activities that may increase the potential of adverse effects to these species on and adjacent to the Project components;
- Specify steps that should be taken to avoid, minimize and mitigate any potential adverse effects on these species; and
- Detail long-term monitoring and reporting goals.

4.5.1 Western Burrowing Owl

Burrowing Owl site use changes temporally. Survey evidence suggests greater use of the Project site by burrowing owl outside of the breeding season, with only two pairs observed remaining to attempt reproduction in 2013.

Although burrowing owls exhibit high burrow fidelity, surveys at the Project site documented dynamic occupancy of burrows in response to changing conditions. If an annual determination of site use and/or breeding success is intended, Phase II and Phase III surveys should be implemented annually across the site, beginning every spring.

If the intent of surveys is limited to the detection of burrowing owls prior to construction, it is recommended that no further action be taken until the Project nears construction. Phase II and Phase III surveys should be conducted 30-days prior to construction in an effort to confirm burrowing owl occupancy and give project managers enough time to respond to findings.

Burrowing owl Phase II and Phase III surveys should be conducted according to the methods described in, "Burrowing Owl Survey Protocol and Mitigation Guidelines" (Burrowing Owl Consortium, 1993). Burrowing owl surveys should adhere to the frequency and timing described by the "Staff Report on Burrowing Owl Mitigation" (California Department of Fish and Wildlife, 2012).

4.5.2 Golden Eagle

Agency approval of the Avian Work Plan was not granted until after the 2013 golden eagle breeding season. Golden eagle surveys will be performed between December 2013 and May 31st 2014 in order to determine territory occupancy and productivity within 10 miles of the project boundary.

Surveys for breeding and non-breeding bald and golden eagles will be conducted within a 10-mile radius of the Project. Occurrence of non-breeding golden eagles within at least 10 miles of the Project boundary during the courtship season (*e.g.,* late December through early February) will be documented and be used to estimate potential project-related impacts to golden eagles, including: juveniles, sub-adults, adult floaters, and breeding adults.

4.5.3 Elf Owl

The habitat analysis determined that the habitat within the Project site and within a one mile buffer zone surrounding the site footprint is not suitable for elf owl breeding. Although it is possible that migrating owls may occur within the area on an occasional transient basis, there are no habitat patches within the assessed area that meet minimal standards (in terms of patch size, tree density, woodland structure, or cavity density) for elf owl nesting or for a sustained foraging resource.

The habitat assessment for elf owls concluded that "the likelihood of elf owls nesting within the Desert Quartzite site or the adjacent one mile buffer zone is very small, approaching zero." Thus, no mitigation is recommended for this species.

4.5.4 Nesting Raptor/Raven Surveys

A Common Raven Management Plan should be developed for the Project. The primary objective of the plan is to protect the juvenile and hatchling desert tortoises from predation by common ravens. This should be accomplished in part by eliminating or minimizing all aspects of human impact that attract ravens (i.e., garbage, surface water, animal and plant waste materials, perching sites, nesting sites, and roosting sites). The secondary objective is to avoid lethal removal of ravens by installing passive bird deterrents. The final objective of this plan is to comply with the regional management actions of the agencies cooperating in the effort to promote tortoise recovery (USFWS 2008b). A BBCS plan will be written and approved by the agencies that will cover these issues.

4.6 MAMMALS

4.6.1 Small Mammals

No special status species were found during the trapping activities, therefore, there are no recommendations.

4.6.2 Desert Kit Fox

Six dens were found to be active on the project site. A Desert Kit Fox Management Plan should be developed, covering avoidance, exclusion and hazing methodology.

4.6.3 Bats

Due to the potential presence of bat species within the Project site, BBCS should be developed. The goal of the BBCS would be to reduce the potential risks for avian and bat mortality potentially resulting from construction and operation of the Project. The objectives of this plan are as follows.

- Identify baseline conditions for raptor and bat species currently present at the Project components;
- Identify construction and operational activities that may increase the potential of adverse effects to these species on and adjacent to the Project components;
- Specify steps that should be taken to avoid, minimize and mitigate any potential adverse effects on these species; and
- Detail long-term monitoring and reporting goals.

4.7 COMPENSATORY MITIGATION

Consistent with BLM NECO requirements and conditions likely to be imposed on the Project by CDFW and USFWS, areas of desert tortoise habitat should be acquired to partially offset the potential adverse effects of the Project. A Compensatory Mitigation Plan, or Habitat Compensation Plan, would be a valuable tool to document the details of mitigation opportunities. Land acquisition should be considered the first priority; however, it is evident that the land purchase opportunities within the Colorado Desert are limited. Supplemental mitigation actions may need to be considered and approved by the agencies. These actions could be in the form of habitat restoration and enhancement throughout the Colorado Desert. Continued coordination with the BLM, CDFW, and USFWS would be beneficial in identifying all possible compensatory mitigation opportunities as they arise.

APPENDIX B SPECIES DETECTED (NON-AVIAN)-PRIMARY STUDY AREA

Appendix B: Species Detected-(Non-Avian)-Primary Study Area

Reptiles		
Desert Tortoise	*Gopherus agassizii*	O,C
California Kingsnake	*Lampropeltis getula californiae*	O
Coachwhip	*Masticophis flagellum*	O
Desert Horned Lizard	*Phrynosoma platyrhinos*	O, S
Desert Iguana	*Dipsosaurus dorsalis*	O, S
Desert Spiny Lizard	*Sceloporus magister*	O
Glossy Snake	*Arizona elegans*	O
Gopher Snake	*Pituophis catenifer*	O
Long-nosed Leopard Lizard	*Gambelia wislizenii*	O
Long-tailed Brush Lizard	*Urosaurus graciosus*	O
Mojave Fringe Toed Lizard	*Uma scoparia*	O
Side-blotched Lizard	*Uta stansburiana*	O
Sidewinder	*Crotlus cerastes*	O
Wesertn Banded Gecko	*Coleonyx variegatus variegatus*	O
Western Patch-nosed Snake	*Salvadora hexalepis*	O
Western Shovel-nosed Snake	*Chionactis occipitalis*	O
Western Whiptail	*Cnemidophorus tigris*	O
Zebra-tailed Lizard	*Callisaurus draconoides*	O
Mammals		
Arizona Myotis	*Myotis occultus*	O
Black-tailed Jackrabbit	*Lepus californicus*	O, T, S
Burro Deer	*Odocoileus hemionus eremicus*	O, T, S
California Leaf-nose Bat	*Macrotus californicus*	O
California Myotis	*Myotis californicus*	V
Canyon Bat	*Parastrellus hesperus*	V
Cave Myotis	*Myotis velifer*	O
Coyote	*Canis latrans*	T, S, B
Desert Cottontail	*Sylvilagus audubonii*	O, T, S, B
Desert Kangaroo Rat	*Diodomys deserti*	O, B
Desert Kit Fox	*Vulpes macrotis arsipus*	B, T, S
Desert Woodrat	*Neotoma lepida*	O, B
Hoary Bat	*Lasiurus cinereus*	V
Little Pocket Mouse	*Perognathus longimembris*	O
Long-tailed Pocket Mouse	*Chaetodipus spp.*	O
Merriam's Kangaroo Rat	*Dipodomys merriami*	O, B
Mexican Free-tailed Bat	*Tadarida brasiliensis*	V
Pallid Bat	*Antrozous pallidus*	V
Palm Spring Round-tailed Ground Squirrel	*Spermophilus teriticaudus chlorus*	O
Small-footed Myotis	*Myotis ciliolabrum*	V
Southern Grasshopper Mouse	*Onychomys torridus*	O, B
Townsend's Big-eared Bat	*Corynorhinus townsendii*	O, V
Western Red Bat	*Lasiurus blossevillii*	O

Appendix B: Species Detected-(Non-Avian)-Primary Study Area

Mammals (continued)		
White-tailed Antelope Ground Squirrel	*Ammospermophilus leucurus*	O
Yuma Myotis	*Myotis yumanensis*	V

O – Observed Directly
B – Burrow
T – Tracks
V – Vocalization
S – Scat
C – Carcass

APPENDIX C SPECIAL STATUS TARGET PLANT SPECIES

Appendix C: Special Status Target Plant Species

Scientific Name **Common Name**	**Status**		**Flowering Period**	**Occurrence on site**
Abronia villosa var. *aurita* chaparral sand-verbena	Global Rank: Federal Listing: State Listing: State Rank: CNPS Rank: NECO:	G5T3T4 none, BLM sensitive none S2 1B.1 not covered	Jan - Sept	Presumed absent; potential habitat present on site but not found during surveys
Acleisanthes longiflora angel trumpets	Global: Federal: State Listing: State Rank: CNPS Rank: NECO:	G5 none none S1 2.3 covered	May	Presumed absent: no suitable habitat onsite (rocky carbonate canyon bottoms).
Astragalus insularis var. *harwoodii* Harwood's milkvetch	Global: Federal Listing: State Listing: State Rank: CNPS Rank: NECO:	G5T3 none none S2 2.2 covered	Jan - May	**PRESENT:** 13,712 individuals estimated on site.
Astragalus lentiginosus var. borreganus Borrego milk-vetch	Global: Federal Listing: State Listing: State Rank: CNPS Rank: NECO:	G5T4T5 none none S3.3 4.3 covered	Feb - May	Presumed absent: potential habitat present on site but not found during surveys
Astragalus lentigunosis var. *coachellae* Coachella valley milk-vetch	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G5T2 none; BLM sensitive none S2 1B.2 covered	Feb - May	Presumed absent: potential habitat present on site but not found during surveys

Appendix C: Special Status Target Plant Species

Scientific Name **Common Name**	**Status**		**Flowering Period**	**Occurrence on site**
Astragalus sabulonum gravel milk-vetch	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G5 none none S2 2.2 not covered	Feb - July	Presumed absent: potential habitat present on site but not found during surveys
Calliandra eriophylla pink fairy-duster	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G5 none none S2S3 2.3 not covered	Jan - Mar	Presumed absent: potential habitat present on site but not found during surveys
Carnegia gigantea saguaro	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G5 none none S1 2.2 covered	May - June	Absent: not found during surveys, little potential habitat on site.
Castela emoryi Emory's crucifixion-thorn	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G4 none none S2S3 2.3 covered	Apr - Jul	Absent; potential habitat present on site but not found during surveys
Euphorbia abramsiana =*Chamaesyce abramsiana* Abrams' spurge	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G4 none none S2S3 2.2 not covered	Sep – Nov	**PRESENT:** appx. 2104 individuals found during Fall 2012 surveys

Appendix C: Special Status Target Plant Species

Scientific Name **Common Name**	**Status**		**Flowering Period**	**Occurrence on site**
Euphorbia parryi	Global:	G5	May - June	Presumed absent: potential habitat present on site but not found during surveys
=*Chamaesyce parryi*	Federal Listing:	none		
Parry's spurge	State Listing:	none		
	State Rank:	S1		
	CNPS:	2.3		
	NECO:	not covered		
Euphorbia platysperma	Global:	G3	Feb - Sep	Presumed absent: potential habitat present on site but not found during surveys
=*Chamaesyce platysperma*	Federal Listing:	none; BLM sensitive		
flat-seeded spurge	State Listing:	none		
	State Rank:	S1		
	CNPS:	1B.2		
	NECO:	not covered		
Colubrina californica	Global:	G4	Apr - Jun	Absent: not found during surveys; no potential habitat on site (rocky wash bottoms & margins)
Las Animas colubrina	Federal Listing:	none		
	State Listing:	none		
	State Rank:	S2S3.3		
	CNPS:	2.3		
	NECO:	not covered		
Coryphantha alversonii	Global:	G3	Apr - Jun	Absent: potential habitat present on site but not found during surveys
foxtail cactus	Federal Listing:	none		
	State Listing	none		
	State Rank:	S3.2		
	CNPS:	4.3		
	NECO:	covered		
Cryptantha costata	Global:	G4G5	Jan - May	**PRESENT:** appx. 56,748 individuals estimated on site
ribbed cryptantha	Federal Listing:	none		
	State Listing	none		
	State Rank:	S3.3		
	CNPS:	4.3		
	NECO:	not covered		

Appendix C: Special Status Target Plant Species

Scientific Name **Common Name**	**Status**		**Flowering Period**	**Occurrence on site**
Ditaxis clariana glandular ditaxis	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G4G5 none none S1 2.2 covered	Dec - Mar	Presumed absent: potential habitat present on site but not found during surveys
Ditaxis serrata var. *californica* California ditaxis	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G5T2T3 none none S2 3.2 covered	Apr - Nov	presumed absent: potential habitat present on site but not found during surveys
Eriastrum harwoodii Harwood's eriastrum	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G3 none; BLM sensitive none S3 1B.2 not covered	Mar - May	**PRESENT:** appx. 882 individuals found on site
Funastrum utahense Utah vine milkweed	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G4 none none S3.2 4.2 not covered	Apr - Sep	**PRESENT:** 1 individual found on site
Helianthus niveus ssp. *tephrodes* Algodones Dunes sunflower	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G4T2 none Endangered S2 1B.2 not covered	Mar - May Oct - Jan	Absent: potential habitat present on site but not found during surveys

Appendix C: Special Status Target Plant Species

Scientific Name **Common Name**	**Status**		**Flowering Period**	**Occurrence on site**
Hymenoxys odorata bitter hymenoxys	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G5 none none S2 2 not covered	Feb - Aug	Absent: no suitable habitat on site (moist river margins and benches)
Imperata brevifolia California satintail	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G2 none none S2.1 2.1 not covered	Sep - May	Absent: no suitable habitat on site (moist river plains & canal margins)
Koeberlinia spinosa ssp. *tennuispina* Crown-of-Thorns	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G4T4 none none S2.2 2.2 covered	Mar - Jul	Absent: potential habitat present on site but not found during surveys
Mammillaria grahamii var. grahamii Graham's fishhook cactus	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G4T4 none none S2 2.2 not covered	Apr	Absent: potential habitat present on site but not found during surveys
Mentzelia puberula Darlington's blazing star	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G4 none none S2 2.2 not covered	Mar - May	Absent: no potential habitat present on site (rocky limestone and granite slopes)

Appendix C: Special Status Target Plant Species

Scientific Name **Common Name**	**Status**		**Flowering Period**	**Occurrence on site**
Opuntia wigginsii Wiggins' cholla	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G3?Q none none S1? 3.3 covered	Mar - June	Absent: potential habitat occurs on site but not found during surveys. Questionable taxonomic validity.
Penstemon pseudospectabilis ssp. *speudospectabilis* desert beardtongue	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G4G5T3T5 none none S3 2.2 not covered	Mar - May	Presumed absent: potential habitat present on site but not found during surveys
Physalis lobata lobed cround cherry	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G5 none none S2 2.3 covered	May - Jan	Presumed absent: potential habitat present on site but not found during surveys
Portulaca halimoides desert portulaca	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G5 none none S3 4.2 not covered	Sept	Presumed absent: potential habitat present on site but not found during surveys
Proboscidea althaefolia desert unicorn-plant	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G5 none none S3.3 4.3 covered	May - Aug	**PRESENT:** appx. 811 individuals estimated during Fall 2012 surveys

Appendix C: Special Status Target Plant Species

Scientific Name **Common Name**	**Status**		**Flowering Period**	**Occurrence on site**
Teucrium cubense ssp. *depressum* dwarf germander	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G4G5T3T4 none none S2 2.2 not covered	Mar - Nov	Presumed absent: marginal habitat present on site but not found during surveys
Wislizenia refracta var. *refracta* jackass clover	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G5T5? none none S1 2.2 not covered	Apr - Nov	Presumed absent: potential habitat present on site but not found during surveys
Wislizenia refracta var. *palmeri* Palmer's jackass clover	Global: Federal Listing: State Listing: State Rank: CNPS: NECO:	G5T2T4 none none S1 2.2 covered	Jan - Dec	Presumed absent: potential habitat present on site but not found during surveys

APPENDIX D QUARTZITE MIGRATORY BIRD SURVEY PROTOCOL

Quartzite Migratory Bird Survey Protocol

Prepared for
IRONWOOD CONSULTING INC.
20 Nevada Street, Suite 300
Redlands, CA 92373

Prepared By:
***Corvus* Ecological Consulting, LLC**
7810 Highway 89, Suite 270
Flagstaff, AZ 86004

April, 2013

I. Equipment:

Binoculars
Spotting Scope (30X or greater)
GPS
Kestrel (thermometer/ anemometer)
Clipboard
Quartzite Migratory Bird Survey Data Sheet (s)
Pen (permanent ink)
Time-keeper (e.g. watch or cell phone)
Compass

II. Migration Survey Point Explanation

The purpose of these surveys is to record the passage of birds migrating over the Desert Quartzite Solar Project (Project) and depict their activity during transit.

- Migration surveys are conducted weekly from each observation survey point from 15 March through 31 May (spring migration) and from 1 September through 15 November (fall migration).

The two Migration survey Points (MP01 and MP02) are strategically located to bisect the Project footprint along the central east-west axis and are situated with near 360 degree views of the distant horizon to maximize visual capture of migrating birds as they pass over the area.

Survey Point	UTM (WGS 84)	
MP01	710176	3717195
MP02	706914	3717170

Flapping flight is energetically expensive and therefore migratory flights are strongly correlated with advantageous weather conditions. Many birds (especially raptors) select the warmest part of the day for migratory movement. Because the Project topography is generally flat and lacking in features likely to generate orographic lift;

- Migration point surveys will be conducted from 10 a.m. through 3 p.m. when thermal lift is greatest.
- Infinite distance visual surveys

A portion of the Project avian community is resident (non-migratory). Residents and some migrants (e.g. soaring raptors) can be expected to circulate and have the potential to be tallied more than once. To reduce the influence of resident birds on the survey data;

- Birds will only be recorded as they pass the axis line and not on subsequent returns. (See IV. Migration Survey Procedures.)

III. Data Sheet Explanation:

Surveyors will use the Quartzite Migratory Bird Survey Data Sheet to record;

A. Daily Information

- Observer: First initial of the first name followed by entire last name. Example, John Doe is recorded as: J. DOE
- Date: (DD Mmm YYYY): e.g. 15 Apr 2013
- Location: Quartzite
- Point ID: Unique identifier for the survey point (MP01 or MP02)

B. Environmental Observations

Weather data is collected for correlation of migration activity with environmental conditions.

- Start Time: 10 a.m.
- Time**:** Start of hourly weather interval
- Precipitation (Yes or No)
- Visibility (in kilometers): Estimate of how far the observer can see across the landscape. Use visible landmarks to aid in this determination.
- Wind Speed (Average MPH): Record the Average Wind Speed in miles per hour. A Kestrel (or similar measuring tool) should be used to record current wind conditions.
    i. First, determine the direction from which the wind is blowing. Position the anemometer in a location that is free from wind obstruction (clear from the leeward side of a tree, shrub or vehicle; top of a wash bank rather than a drainage bottom).
    ii. Hold the anemometer above head height and turn it on. Scroll to the device's "average" setting and allow it to record for two minutes. **NOTE: These devices will begin to average the wind speed from the second they are turned on and therefore they should be in position to record accurate conditions from the moment they are turned on until the moment the value is captured*.
- Wind Direction (8-point cardinal): Direction from which the wind is emanating (e.g. SW)
- Temperature (ºC): *Temp (^oC)* = Record the Temperature in degrees Celsius.
    i. Hold the Kestrel or thermometer in a shaded location, approximately three-feet above the ground surface.

ii. Allow the temperature reading to stabilize before recording the value. With a digital thermometer (such as a Kestrel) this point can be determined by the appearance of an unchanged value for 20 seconds or when the value suddenly changes direction from which it was adjusting, such as when the value increases after a consistent downward adjustment.

- Cloud cover (%): Visually estimate the amount of the sky covered by cloud

C. Bird Observations

1. Time: Timestamp at which a bird crosses the east-west axis
2. Species Code: 4-letter Alpha code (Institute for Bird Populations 2012; http://www.birdpop.org/DownloadDocuments/Alpha_codes_eng.pdf)
3. Number of Individuals: The number of birds (of the same species) detected passing over the axis and not returning. If birds are obviously grouped together, record the number of individuals in the same-species group. If birds are separated by enough space to warrant recording significantly different distances, flight heights or behaviors for each, record those birds on separate lines (e.g. write CLSW in "Species code" on three different lines if there are three Cliff Swallows detected at three completely different height codes).
4. Flight Direction: (8-point cardinal): Direction in which the bird is flying away from the observer and travelling across the Project (e.g. NW).
5. Distance from Observer: Record (in meters) the distance of each bird from the observation point as it crosses the axis.
6. Flight Height: Record the **lowest flight height observed** with one of the following codes:

- 1 = 0-4m (height of a PV Panel)
- 2 = 4-10m (height of a 3-storey building)
- 3= 10-50m (height of a transmission tower)
- 4=50m+ (higher than a transmission tower)

7. Behavior: Record the **behavior best characterizing use of the Project area** with one of the following codes;

- F=Foraging
- FA= Flapping
- SO=Soaring
- GL=Gliding
- S=Singing
- C=Calling
- O=Other

8. Age Class: Record A=Adult or I=Immature for raptors

IV. Migration Survey Procedures:

UN-codes. Infinite distance visual surveys rely on surveyors competently combining subtle clues such as silhouetted profile, wing beat rate, and flight pattern to accurately identify distant birds under less than ideal lighting conditions. Recognizing that not all birds can be identified to species under all conditions at all distances, the Alpha abbreviations contain UN-codes;

Alpha	Bird Group
UNBI	Unidentified Bird
UNEM	Unidentified Empidonax Flycatcher
UNGU	Unidentified Gull
UNHA	Unidentified Hawk
UNHU	Unidentified Hummingbird
UNWA	Unidentified Warbler

- Use UN- codes to record birds to the highest resolution possible

Double-Counting. Care must be taken to avoid double-counting. The goal of these surveys is to account for individuals of a given species no more than one time during the migration survey period. Some birds may be expected to be residents with territories that encompass the survey point. For example, a Red-tailed Hawk may be foraging over the area even as others are passing through, so the surveyor should attempt to exclude repeat tallies of such non-migrants.

Additional Observations. There may be additional bird sightings that observers wish to record that can provide benefit to the project but are not relevant to the particular survey, e.g. breeding or wintering bird observations. These observations should be recorded and passed along to the Avian Lead to assist with the depiction of avian breeding or distributional data within the Project area. To be of maximum value, each observation should include UTMs, a date and timestamp, and thorough details.

If surveyors have any questions about this protocol, please ask them *before* conducting the survey!

APPENDIX E QUARTZITE AVIAN LINE-TRANSECT SURVEY PROTOCOL

Quartzite Avian Line-Transect Survey Protocol

Prepared for
IRONWOOD CONSULTING INC.
20 Nevada Street, Suite 300
Redlands, CA 92373

Prepared By:
***Corvus* Ecological Consulting, LLC**
7810 Highway 89, Suite 270
Flagstaff, AZ 86004

March, 2013

Materials/ Supplies:

Binoculars
GPS
Kestrel (thermometer/ anemometer)
Rangefinder
Clipboard
Data Sheet(s)
Notepad (for recording personal notes not relevant to data sheets)
Pen (permanent ink)
Watch or other portable clock (e.g. cell phone)
Compass

Line-Transect Explanation

- Check your GPS settings to insure that the Map Datum is "WGS 84;" that the Compass Heading > North Reference is set to, "Magnetic;" and that "Metric" is the selected unit of measurement for "distance/ speed."
- Line-transect will be 2000 meters in length, with a starting point and ending point (Fig. 1).

Figure 1.0. Line-transect route, 2000 meters long from point A to point B.

- Surveyors will begin the route from either point. For each line, point A should be used as a starting point 50% of the occasions it is surveyed, point B serving as starting point the other 50% of occasions it is surveyed.
- Surveyors will record distance (in meters) to each bird detected, measuring distance perpendicular (90°) to the line. Birds will not be recorded more than 90° from the line before the starting point or after the ending point. [See Methods/ Procedures for details.]
- ***Please be sure to read this entire document prior to starting your first survey***.

Data Sheet Explanation:

Surveyors will use the Quartzite Avian Line-Transect Data Sheet.

1. Line-Transect Data Sheet fields:

a. Complete the data sheet header including: Observer name, Date, Location, Transect ID, Starting point (circle A or B), Start time, and weather data prior to beginning a point count.

b. Observer(s) names: First initial of first name followed by entire last name. Example, John Doe is recorded as: J. DOE

c. Date: In DD MMM YYYY format. For example: 02 MAR 2011

d. Site Name: Locations to include: Project Footprint (within the proposed project boundary) or Project Control (outside of the proposed Project Footprint).

e. Transect ID: Unique identifier for the transect.

f. WGS 84, UTM: Provide the UTM coordinates for the starting location (A or B).

To Record Start Times and Weather Data: The purpose of collecting weather data is to provide support that environmental conditions are conducive to performing an avian line-transect survey. If conditions cause the observer to feel that results of a survey would be biased due to poor weather, the survey should be postponed until weather conditions improve. Some examples of weather conditions that are grounds for postponement include: average wind speeds greater than 15 miles per hour, visibility 2.0 miles or less, heavy rain/ fog or extreme temperatures.

1. *Record the start time.*
   i. The start time should represent the moment when observers initiate a search effort exclusive to the "transect" being surveyed; i.e. after initial information is recorded in the header of the data sheet, immediately before beginning to search for birds.
2. *Precip (Y/N)* = Precipitation, "Yes" or "No" for the entire survey period.
3. *Visibility (Miles)* = Estimate of how far the observer can see (in miles) across the landscape. Use visible landmarks to aid in this determination.
4. *Wind (AVG MPH)* = Record the Average Wind Speed in miles per hour. A Kestrel (or similar measuring tool) should be used to record current wind conditions.
   i. First, determine the direction from which the wind is blowing. Position the anemometer in a location that is free from wind obstruction (clear from the leeward side of a tree, shrub or vehicle; top of a wash bank rather than a drainage bottom).

ii. Hold the anemometer above head height and turn it on. Scroll to the device's "average" setting and allow it to record for two minutes. **NOTE: These devices will begin to average the wind speed from the second they are turned on and therefore they should be in position to record accurate conditions from the moment they are turned on until the moment the value is captured.*

5. *Temp (^oC)* = Record the Temperature in degrees Celsius.
   i. Hold the Kestrel or thermometer in a shaded location, approximately three-feet above the ground surface.
   ii. Allow the temperature reading to stabilize before recording the value. With a digital thermometer (such as a Kestrel) this point can be determined by the appearance of an unchanged value for 20 seconds or when the value suddenly changes direction from which it was adjusting, such as when the value increases after a consistent downward adjustment.
6. *Cloud Cover (%)* = A visual estimation which determines the percentage of visible sky that is covered by clouds.

- <u>Recording Data</u>

A. *Species code*: This is a bird's standardized four letter code. Appendix A contains the project related short list of codes for easy reference, if any are missing please reference: http://www.birdpop.org/DownloadDocuments/Alpha_codes_eng.pdf

B. *Detection type* (A, V): How the bird was **initially** detected; A = Audio and V = Visual. **NOTE: these codes are listed at the bottom of the data sheet.*

C. *Flight height (1, 2, 3 or 4)*: Record **lowest flight height observed** as one of the following numbers (1 through 4): 1 = 0-4m (height of a tall PV panel), 2 = 4-10m (height of a three-story building), 3 = 10-50m (height to top of transmission tower), 4 = 50m+ (higher than top of transmission tower). **NOTE: these codes are listed at the bottom of the data sheet.*

F. *Number (#) of individuals*: the number of birds detected (of the same species). If birds are obviously grouped together, record the number of individuals in the same-species group. If birds are separated by enough space to warrant recording significantly different distances for each, or if birds are located in significantly different directions, record those birds on separate lines (e.g. you can write BTSP in "Species code" on three different lines if there are three Black-throated Sparrows detected in three completely different directions; for each BTSP you

would write "1" under "# of individuals.") **Important note:** Do not count eggs or young birds that are not yet independent from their parents as "individuals."

G. *Radial distance (meters)*: perpendicular (90°) distance from the transect, in meters. If distance cannot be accurately recorded at 90° from the line-transect: record a straight line distance from the observer to the bird, AND record the size of the angle formed between the straight line to the bird and the line-transect itself. (*This is recorded in the column "Bearing (degrees)" – see below.*) **Important note:** If recording a single distance for a "cluster" of the same species, use the estimated distance to the *center of the cluster*. These are "unlimited distance surveys" and there is no limit to the perpendicular distance which detections may be made.

H. *Bearing (degrees)*: if the distance recorded to the bird(s) is made at a 90° angle, leave this field blank. Generally, this will be the case. However, if the surveyor finds it necessary to record a straight line distance to the bird - for example if writing furiously after encountering a flock of birds, or if a large obstruction such as a tree blocks the view at 90° - use this column to record the size of the angle (in degrees) formed where the surveyor is the axis, the line-transect is the adjacent side of the angle, and the straight line between the surveyor and the bird is the hypotenuse side of the angle. (The "opposite" side, which is situated 90° from the line-transect, can then be automatically calculated during data analysis.)

I. *Behavior code*: See Appendix B for a complete explanation of each behavior code. Multiple codes can be used, separated by commas (for example: C, S), but please list the *initial* behavior code first. ***NOTE: these codes are listed with brief definitions at the bottom of the data sheet.***

J. *Comments*: Observers may enter comments that they feel are relevant to any detection. It is a good idea to enter a comment such as "no data" if observers did not have a detection on the line-transect so that data checkers can keep track of progress and know that there is not data missing. If an individual bird is counted as an "incidental" and recorded again during the station survey, a comment should be made indicating such. **Note**: Any incidental sightings should be entered into pendragon, not on the transect data form.

Line-Transect Survey Methods/ Procedures:

AR060597

Once observers/ surveyors are within 200 meters of a start point they should record the initial data found in the header of the data sheet, except for Start Time. Start Time should be recorded when the surveyor arrives at the beginning of the line-transect, immediately before beginning to survey the transect.

Access the starting point and record any incidental (I) sightings while in route into pendragon. Because line-transect surveys tend to generate many more detections than a traditional point-count or point-transect, and therefore take longer to conduct, incidental sightings should be limited to noteworthy detections. Examples include: a new species for the project site list; a species not likely to be encountered again during the particular line-transect survey; a bird exhibiting breeding behavior; or any other reason the surveyor feels it necessary to document a particular incidental sighting as "data."

Once at the starting point for the line-transect, begin the count period by recording the Start Time. Birds that flush from the line-transect during approach should be included in the survey period and documented by recording the distance to the bird's initial position, prior to flushing. Detections should include a value for: "Species code," "Detection type," "Flight height," "Number (#) of individuals," "Radial distance," "Bearing," and "Behavior code" (if applicable). Observers should travel slowly or stop occasionally along the line to listen for vocalizations and to search dense areas of cover. Try to move as quietly as possible to maximize aural detections. A relatively constant pace should be maintained, but take the time needed to confidently identify every bird detected. Don't forget to scan the sky as well as the surrounding habitat, to maximize probability of detection for all upland species (especially raptors).

Once a line-transect has been completed, observers should record "End time". The surveyor should then access the next line-transect as soon as possible, if surveying a second transect that day. Any bird detection made after the "End time" has been recorded at the ending point should be recorded as an incidental detection in pendragon (even if surveyor is still at the ending point). Bird detections made between transects are recorded as incidental sightings, as well.

Care must be taken to avoid double-counting. The goal is to account for individuals of a given species no more than one time during the line-transect survey period; the exception to this rule being "incidental" detections. A bird recorded as an incidental may be recorded again during the official line-transect survey, but observers should provide a comment that indicates as much. It is important to separate incidental sightings from transect sightings for the purpose of data analysis but it is also important that we account for as many species/ individuals as possible during each survey. Once an observer has traveled more than 200 meters from the last station they should take final weather data and record any final comments on the data sheet.

There may be additional bird sightings that observers wish to record that can provide benefit to the project but are not relevant to the particular survey. Additional sighting should be recorded in the Incidental pendragon form, where they may provide beneficial migratory or distributional data.

APPENDIX F QUARTZITE FALL 2012 AND SPRING 2013 PLANT LIST

Appendix F: Quartzite Fall 2012 and Spring 2013 Plant List

Scientific Name	Family	Abundance
Abronia villosa	Nyctaginaceae	Common
Achyronchia cooperi	Caryophyllaceae	Occasional
Acmispon strigosus	Fabaceae	Common
Allionia incarnata	Nyctaginaceae	Occasional
Ambrosia dumosa	Asteraceae	Common
Ambrosia salsola	Asteraceae	Scarce
Aristida adscensionis	Poaceae	Occasional
Aristida oligantha	Poaceae	Scarce
Asclepias subulata	Apocynaceae	Scarce
Astragalus aridus	Fabaceae	Locally common
Astragalus didymocarpus	Fabaceae	Occasional
Astragalus insularis var. harwoodii	Fabaceae	Locally common
Astragalus nuttallianus var. imperfectus	Fabaceae	Locally abundant
Atriplex canescens	Chenopodiaceae	Scarce
Atriplex polycarpa	Chenopodiaceae	Scarce
Baileya pauciradiata	Asteraceae	Occasional
Bebbia juncea	Asteraceae	Scarce
Boerhavia triquetra var. intermedia	Nyctaginaceae	Locally common
Boerhavia wrightii	Nyctaginaceae	Common
Bouteloua aristidoides	Poaceae	Occasional
Bouteloua barbata	Poaceae	Occasional
**Brassica tournefortii*	Brassicaceae	Common / Locally abundant
Calocoseris wrightii	Asteraceae	Occasional
Caulanthus lasiophyllus	Brassicaceae	Occasional
Chaenactis carphoclinia	Asteraceae	Occasional
Chaenactis stevioides	Asteraceae	Abundant
**Chenopodium album*	Chenopodiaceae	Scarce

Appendix F: Quartzite Fall 2012 and Spring 2013 Plant List

Scientific Name	Family	Abundance
**Chenopodium murale*	Chenopodiaceae	Scarce
Chorizanthe brevicornu	Polygonaceae	Occasional
Chorizanthe corrugata	Polygonaceae	Occasional
Chorizanthe rigida	Polygonaceae	Occasional
Chylismia brevipes	Onagraceae	Scarce
Chylismia claviformis ssp. aurantiaca	Onagraceae	Common
Croton californicus	Euphorbiaceae	Scarce
Cryptantha angustifolia	Boraginaceae	Abundant

	Western Tanager	*Piranga ludoviciana*	MBTA			
Blackbirds (Icteridae)						
	Red-winged Blackbird	*Agelaius phoeniceus*	MBTA			
	Yellow-headed Blackbird	*Xanthocephalus xanthocephalus*	MBTA			SSC
	Brewer's Blackbird	*Euphagus*	MBTA			

Quartzite Avian Species List Spring 2013

BCC = Bird of Conservation Concern, **BLM**S = BLM Sensitive, **FP** = Fully Protected, **SSC** = Species of Special Concern, **ST** = State Threatened, **MBTA** = Migratory Bird Treaty Act

Family	Common Name	Scientific Name	Federal Status	State Status	BLM Status	Other Status
		cyanocephalus				
	Great-tailed Grackle	*Quiscalus mexicanus*	MBTA			
	Brown-headed Cowbird	*Molothrus ater*	MBTA			
	Bullock's Oriole	*Icterus bullockii*	MBTA			
Fringilline and Cardueline Finches and Allies (Fringillidae)						
	House Finch	*Haemorhous mexicanus*	MBTA			

APPENDIX H PHASE III BURROWING OWL SURVEY RESULTS, 2013

Appendix H: Phase III Burrowing Owl Survey Results, 2013

Waypoint ID	Date	Initial Burrow Class	Current Burrow Class	# of Adults	# of Juveniles	*Nest Status	Comments
CVS153	5/18/2013	1	4	0		D	Collapsed burrow no longer suitable for BUOW use.
CVS164	5/25/2013	2	4	0	0	U	No BUOW sign present. Class=4.
DNF702	5/28/2013	3	4	0	0	U	Canid complex, no BUOW sign, fresh Canid excavation.
DNF702	7/12/2013	3	4	0	0	U	Well presented canid complex. Rain on 10-11 July has erased old sign. Kit fox pellets remain.
DNF703	5/30/2013	3	3	0	0	U	-No tracks or feathers observed -2 Pellets, neither fresh nor very sun-bleached -Burrow usable
DNF703	6/20/2013	3	3	0	0	U	Considerable old whitewash present. Burrow in good condition with clean entrance. No new sign observed.
DNF703	7/12/2013	3	3	0	0	U	Single canid or enlarged rodent burrow. Fair amount of old whitewash despite rain 20-11 July. No new tracks or other BUOW sign.
DNF706	5/28/2013	3	3	0	0	U	No recent BUOW sign, one old whitewash spot.
DNF706	6/19/2013	3	3	0	0	U	-No feathers, tracks or pellets -Single whitewash mark -Burrow usable
DNF706	7/15/2013	3	3	0	0	U	-No feathers, tracks or pellets -Single whitewash mark -Burrow usable
DNF707	5/28/2013	3	3	0	0	U	Single entrance canid, old whitewash, no recent BUOW sign.

Waypoint ID	Date	Initial Burrow Class	Current Burrow Class	# of Adults	# of Juveniles	*Nest Status	Comments
DNF707	6/20/2013	3	3	0	0	U	Small kit fox or large rodent burrow in good condition. No recent sign but old whitewash still present.
DNF707	7/13/2013	3	3	0	0	U	Excellent single canid burrow with 2 fading whitewash spots following rain 10-11 July. No pellets or tracks of any species.
DNF717	5/29/2013	3	2	0	0	U	Clean canid complex with recent whitewash.
DNF717	6/21/2013	3	3	0	0	U	-Dozens of very sun bleached pellets around mound and borough -No feathers or tracks -Borough usable but un-kept and clearly inactive with spider webs and other materials at entrance -Single whitewash mark on sand mound in front of burrow
DNF717	7/15/2013	3	3	0	0	U	Small amount of old whitewash remain on mound. 2 burrows in good condition and many small bones adjacent.
JCW513	5/30/2013	3	3	0	0	U	- No feathers or tracks -5 Partially washed away whitewash marks -No pellets -Burrow usable
JCW513	6/20/2013	3	3	0	0	U	Enlarged rodent burrow in good condition with considerable old whitewash but no recent sign.

Appendix H: Phase III Burrowing Owl Survey Results, 2013

Waypoint ID	Date	Initial Burrow Class	Current Burrow Class	# of Adults	# of Juveniles	*Nest Status	Comments
JCW513	7/15/2013	3	3	0	0	U	-6 Weathered whitewash marks -No feathers, tracks or pellets -Burrow usable
PHK646	5/27/2013	1	4	0	0	U	Active Kit fox den.
PHK647	5/27/2013	1	4	0	0	U	No BUOW sign. Class = 4.
PHK648	5/27/2013	2	4	0	0	U	Appears to have been re-excavated by mammal, end of tunnel visible. No BUOW sign. Class = 4.
PHK683	5/30/2013	3	3	0	0	U	-Pellets observed, none fresh. -White wash accumulated beneath creosote. -Burrow in usable condition
PHK683	6/21/2013	3	3	0	0	U	Pellets and whitewash still present but burrow entrance partially occluded by wind-blown vegetative debris. American Badger obs excavating 5m W did not approach this burrow.
PHK683	7/14/2013	3	3	0	0	U	-Whitewash accumulated beneath creosote and around Burrow -Multiple pellets around borough next to creosote -No feathers or tracks -Burrow usable
PHK684	5/30/2013	2	4	0	0	U	Rodent burrow observed. No whitewash or pellets observed. No sign observed.
PHK701	5/31/2013	2	3	0	0	U	Burrow in good condition with old whitewash but no other sign.

Waypoint ID	Date	Initial Burrow Class	Current Burrow Class	# of Adults	# of Juveniles	*Nest Status	Comments
PHK701	6/21/2013	2	3	0	0	U	Burrow in good condition, more than 2min length. Old whitewash still present but no recent BUOW sign detected.
PHK701	7/15/2013	2	3	0	0	U	-2 Pellets -3 Whitewash marks -No feathers or tracks -Burrow usable
PHK702	5/31/2013	3	3	0	0	U	Good kit Fox burrow with many old whitewash.
PHK702	6/19/2013	3	3	0	0	U	-No feathers, tracks or pellets. -~15 weathered whitewash marks -Burrow usable
PHK712	5/25/2013	3	4	0	0	U	No sign observed. Class = 4.
PHK712	6/20/2013	3	3	0	0	U	Clean large entrance - possibly re-excavated. Sidewinder track into burrow. Owl feathers on mound.
PHK712	7/12/2013	3	3	0	0	U	-Burrow usable -No feathers, tracks or whitewash -3 weathered pellets near burrow
PHK712	7/13/2013	3	3	0	0	U	-Burrow usable -No feathers, tracks or whitewash -3 weathered pellets near burrow
PHK726	5/29/2013	3	4	0	0	U	No activity. Whitewash is old, no recent sign. Burrow inactive and in a state of decay.

Waypoint ID	Date	Initial Burrow Class	Current Burrow Class	# of Adults	# of Juveniles	*Nest Status	Comments
PHK726	6/19/2013	3	3	0	0	U	Burrow in good condition, old whitewash, no recent sign. The
PHK726	7/12/2013	3	3	0	0	U	-No feathers, tracks or pellets -3 weathered whitewash marks -Burrow usable
PHK732	5/29/2013	3	3	0	0	U	No activity. Nest site looks conducive but sign (whitewash) is old.
PHK732	6/19/2013	3	3	0	0	U	One good burrow with old whitewash.
PHK732	7/13/2013	3	3	0	0	U	Canid complex with two entrances: 1 with old whitewash is partially collapsed, 1 with clean entry in excellent condition. No recent BUOW sign. Numerous canid burrows within 150m radius.
PHK761	5/31/2013	3	3	0	0	U	-12 weathered whitewash marks -No feathers, tracks or pellets -Burrow usable -Spiderwebs at entrance
PHK761	6/21/2013	3	3	0	0	U	-Burrow usable -~15 White wash marks at entrance and your burrow -No feathers, tracks or pellets
PHK761	7/15/2013	3	3	0	0	U	Considerable old whitewash at clean entry of CS but no new sign since rain event 10-11 July. No tracks pellets or pretty remains.

Waypoint ID	Date	Initial Burrow Class	Current Burrow Class	# of Adults	# of Juveniles	*Nest Status	Comments
PHK765	5/31/2013	3	3	0	0	U	-No tracks, feathers or pellets observed -Three whitewash marks, not fresh -Burrow usable
PHK765	6/20/2013	3	3	0	0	U	-No feathers, tracks, pellets. -~Five weathered whitewash marks -Burrow usable
PHK765	7/13/2013	3	3	0	0	U	- 3 Weathered whitewash marks -Burrow usable -No feathers, tracks or pellets
PHK768	5/31/2013	2	3	0	0	U	-No feathers or tracks observed -One nearly washed away whitewash mark -One fox pellet
PHK768	6/20/2013	2	3	0	0	U	-Burrow usable. -Whitewash marks on rock in front of burrow nearly weathered away. -No feathers, tracks or pellets. -Kangaroo rat foot near burrow
PHK768	7/13/2013	2	3	0	0	U	-2 Weathered pellets -2 Weathered whitewash marks -No feathers or tracks -1 Kangaroo rat tail at burrow entrance

Waypoint ID	Date	Initial Burrow Class	Current Burrow Class	# of Adults	# of Juveniles	*Nest Status	Comments
PHK775	5/23/2013	3	3	0	0	U	No changes since initial observation.
PHK775	6/22/2013	3	3	0	0	U	Burrow in fair condition, old whitewash and pellet. No recent sign.
PHK775	7/14/2013	3	3	0	0	U	Old whitewash at rodent burrow adjacent to old canid complex with no current viable entrances. Owl burrow in good condition. 1 disintegrating pellet and many small bones / fragments scattered near entrance.
PHK837	5/24/2013	2	1	2	Unknown	UD	One adult at burrow for 2 hrs of observation, second adult 0-150m east overlooking Brassica field.
PHK837	6/20/2013	2	1	1	Unknown	UD	Adult perched 1m agl and 1-5m from burrow entrance for duration of 2.5 hr observation
PHK837	7/14/2013	2	2	0	0	UD	-Whitewash around burrows and accumulated around creosote -Pellets -No feathers or tracks observed -Burrows usable
PHK837	7/15/2013	2	3	0	0	D	Follow up to visit 14 July. 3 burrows with large entries have debris mounds consistent with but not conclusive of predatory excavation. No owl tracks present on mounds where numerous in June. Some whitewash and pellets remain. No prey remains of any species observed.

Waypoint ID	Date	Initial Burrow Class	Current Burrow Class	# of Adults	# of Juveniles	*Nest Status	Comments
PHK842	5/29/2013	3	3	0	0	U	Burrow in good condition, old BUOW sign (whitewash) but no recent indications. Class = 3.
PHK842	6/22/2013	3	3	0	0	U	-~20 sun bleached pellets around dirt mound next to burrow -~10 whitewash marks near burrow entrance -Burrow usable -No feathers or tracks
PHK842	7/16/2013	3	3	0	0	U	-Burrow usable -Sidewinder at entrance -Weathered pellets present -~ 10 weathered whitewash marks -No feathers or tracks
RR0001	5/31/2013	2	4	0	0	U	Canid complex showing recent Coyote and kit fox excavation. No BUOW sign detected.
RR0002	5/22/2013	1	1	2	0		Pale worn adult ranging to east near Brassica field with occasional forays near burrow.
RR0002	5/30/2013	1	1	2	Unknown	U	Pair observed during unrelated survey foraging on territory @ 0830. Second bird is much darker and boldly marked.

Waypoint ID	Date	Initial Burrow Class	Current Burrow Class	# of Adults	# of Juveniles	*Nest Status	Comments
RR0002	6/20/2013	1	1	2	Unknown	U	-Pair perched in same area for over 2 hours, likely guarding. -Pair in view for over two hours, however only activity observed included preening, fanning of wings, perching together, possible nest guarding and female receding occasionally into burrow for extended periods.
RR0002	7/13/2013	1	1	2	Unknown	H	Female entering burrow for 1-2 minutes every 15-20 minutes suggests young in nest. Male ranging 30-120m East of nest.
RR0002	7/15/2013	1	1	2	Unknown	H	Pale adult observed to make food drop to burrow entrance then immediately depart to guard perch, suggesting dependent young in burrow.

* Nest Status: H-Hatchling, U-Unoccupied, UD-Undetermined, D-Destroyed

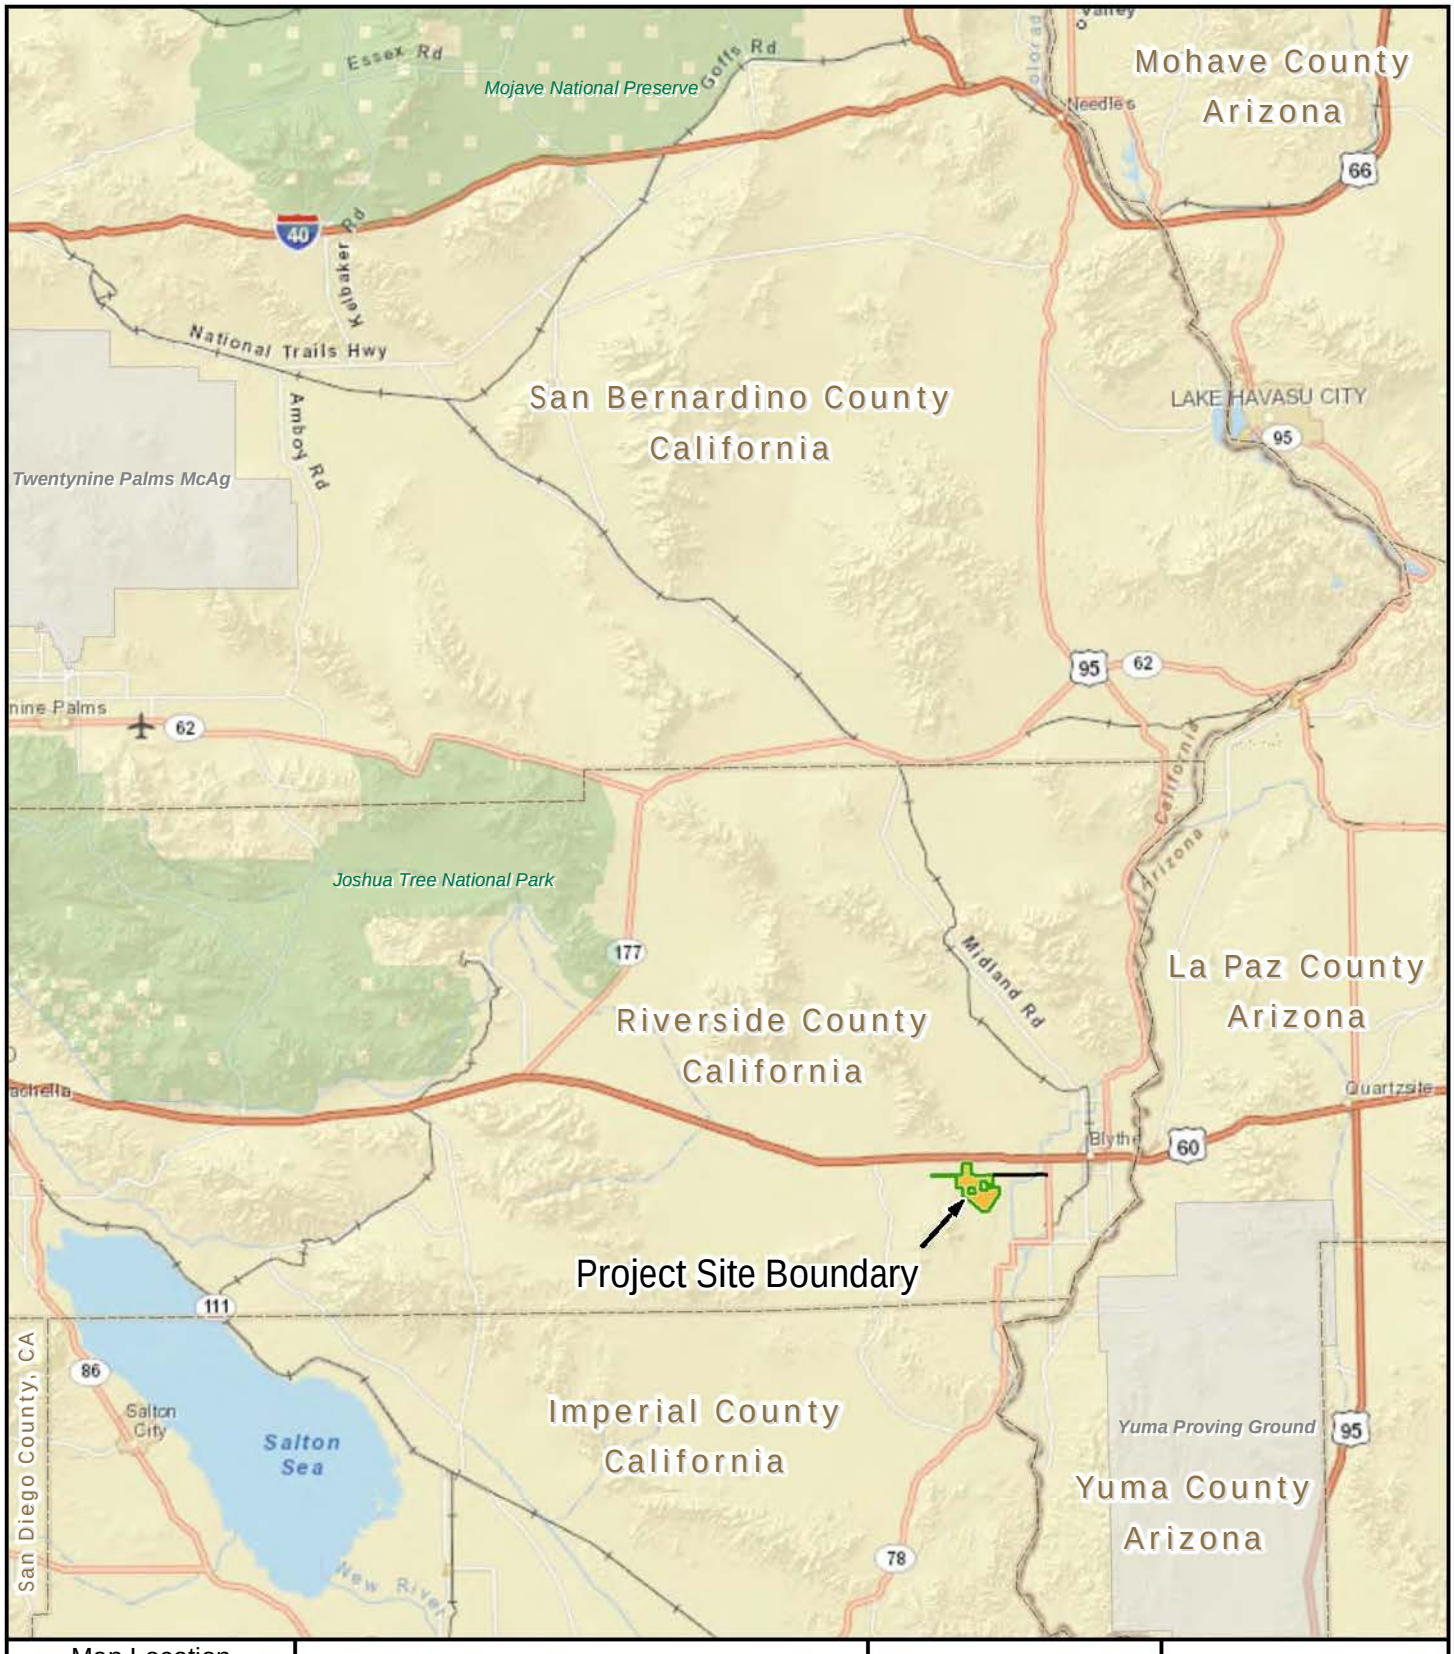
1.0 Introduction

1.1 Type of Facility, Planned Uses, and Generation Output

Desert Quartzite, LLC proposes to construct and operate a 300 megawatt (MW) alternating current (AC) solar photovoltaic (PV) energy-generating project known as the Desert Quartzite Solar Project (Project). Desert Quartzite, LLC is a wholly-owned subsidiary of First Solar Development, Inc. The facility will utilize First Solar's thin-film cadmium telluride (CdTe) PV modules in order to produce clean, renewable energy for sale to one or more California utilities. The right of way (ROW) being requested for the site of the PV generating facility (solar facility) and the corridor for the Project's generation interconnection transmission line (Gen-Tie Line) will be located on lands administered by the U.S. Department of Interior, Bureau of Land Management (BLM). This Plan of Development (POD) is part of the BLM ROW grant application process and has been prepared according to the latest BLM Solar POD Outline guidance, dated December 19, 2012. This POD also includes as Appendix C a Site Plan Package (SPP) that provides preliminary engineering information for the Project.



In this POD, the Solar Facility Site and the 600-foot-wide study corridor for the Gen-Tie Line are collectively referred to as the Project Site. The Project Site is located in eastern Riverside County, California, approximately 2.75 miles southwest of the western edge of the City of Blythe.

Figure 1-1 is a vicinity map of the Project Site (CACA 049397), including the Project Site and surroundings. The proposed Project includes the Solar Facility, an On-Site Substation, and the Gen-Tie Line. The Project proposes to interconnect to the regional transmission grid at Southern California Edison's (SCE's) Colorado River Substation (CRSS), . The CRSS was constructed as part of a system upgrades that are intended to serve several renewable energy projects in the region, including projects that are further along in the development process than the proposed Project. Construction of the CRSS was completed in September of 2013. Because the CRSS is already permitted, constructed, and operational, construction and operation of the CRSS is not analyzed in this POD.

The proposed Project will help California meet its Renewable Portfolio Standard (RPS) goal, which is currently 33 percent of electrical power retail sales by 2020 under Senate Bill (SB) X 1-2. The Project supports Secretary of the Interior Salazar's Orders 3283 and 3285, which make developing renewable energy a top national priority. The Project will also help the State achieve the 2006 Global Warming Solutions Act (Assembly Bill [AB] 32) greenhouse gas (GHG) reduction targets, which require California's GHG emissions to be reduced to 1990 levels by 2020.

When fully operational, the 300 MW Project will deliver over 1.5 billion kilowatt-hours of clean, renewable energy annually. This is equivalent to the amount of energy needed to serve over 90,000 California homes each year. When compared to the carbon dioxide (CO_2) emissions that would be emitted if the same amount of electricity was generated from fossil fuels, implementing the Project will avoid emissions of over 165,000 metric tons of CO_2 annually – the equivalent of taking almost 32,000 automobiles off the road. The electricity generated by the Project will be sold to one or more utilities or other retail customers.

The Project will employ best practices throughout all aspects of development. First Solar's advanced PV technology and an efficient, environmentally sensitive site layout will maximize renewable energy generation potential while minimizing disruption to the Project Site and surrounding environment.

Desert Quartzite, LLC

May 2014

AR060631

Key attributes of the Project include:

- Direct conversion of sunlight to electricity without the use of water (i.e., no need for cooling water or water to generate steam) or production of wastes in the power generation process;
- 300 MW of electrical power, a typical capacity for a modern natural gas-fired combined-cycle power plant in California, generated from a renewable source and producing no carbon (or any other air pollutant) emissions and lower noise levels during power generation;
- A project sited within the Riverside East Solar Energy Zone (SEZ) as designated in the BLM 2012 Approved Resource Management Plan Amendments/Record of Decision (ROD) for Solar Energy Development in Six Southwestern States and within one of the Competitive Renewable Energy Zones (CREZ) identified by the Renewable Energy Transmission Initiative (RETI);
- Low-profile, PV arrays and no on-site structures taller than a maintenance building or electrical switchyard;
- Minimal water use during Project operation; and,
- Desert tortoise exclusion fencing along the site perimeter.

1.2 Project Background

On September 28, 2007, OptiSolar Inc. (OptiSolar) filed an application with the BLM Palm Springs Field Office for development of the Project on approximately 7,245 acres of BLM-administered land located southwest of Blythe. The Project was originally proposed as a 274 MW project using OptiSolar PV technology. OptiSolar submitted a POD for the Project on November 24, 2008, describing the Project as a 601 MW solar PV project on 7,724 acres of BLM-administered land. On April 3, 2009, First Solar, Inc. acquired OptiSolar by merger, resulting in OptiSolar becoming a wholly-owned subsidiary of First Solar, Inc. After the merger, OptiSolar changed its name to First Solar Development, Inc. In accordance with the BLM's case recordation of April 11, 2011, the acreage for CACA 049437 is 7,236 acres. On August 15, 2011, First Solar submitted a revision to the POD that refined and decreased the Project Site Boundary and redesigned the Project using First Solar PV modules. Among the areas removed in the Project Site Boundary was the portion south of the Devers-Palo Verde (DPV) transmission lines. The Project's generation capacity was revised to 300 MW, and at the same time the portion of the Project ROW to be occupied by the Project facilities (Solar Facility and Gen-Tie Line corridor) was reduced to 4,861 acres.

On September 15, 2011, First Solar submitted another revision to the POD that revised the location of the SCE Colorado River Substation and associated 230 kV Gen-Tie Line route, and provided refined Project Description details as well as provided additional figures and exhibits.

On December 13, 2013, First Solar submitted a request to substitute the Applicant/Project Development Entity on the Desert Quartzite SF-299 from First Solar Development, Inc. to Desert Quartzite, LLC. The request also included a revised map (revised Figure 2-2) and legal description of the right-of-way (ROW) application area (revised Table 2-2). The revised ROW application area is 4,843 acres.

At the request of BLM, in March of 2014, Desert Quartzite Solar submitted a minor change to the Gen-Tie Line portion of the ROW identified in the Desert Quartzite SF-299.

1.3 Applicant's Schedule for Project Permitting, Construction, and Operation

The BLM will be the lead Federal agency for approving the Project and will issue a ROW grant authorizing the Project's construction, operation, and use of BLM-administered lands. The decision regarding the issuance of the ROW grant will be based in part on an evaluation of the Project's potential environmental

effects through the National Environmental Policy Act (NEPA) review process and the requirements of the Federal Land Policy and Management Act of 1976 (FLPMA). The NEPA process will involve the preparation of an EIS detailing the Project's expected environmental impacts and mitigation measures to avoid or minimize identified impacts. The NEPA review process will commence once the BLM has deemed the POD complete, issued a Notice of Intent (NOI) to prepare an EIS, and selected a consultant to prepare the EIS. It may take 12 months or more from the formal initiation of the NEPA process to receive all final approvals for the ROW grant.

The Project Site is located within the boundaries of the area administered under the Northern and Eastern Colorado (NECO) Plan, an element of the California Desert Conservation Area Plan of 1980 as Amended (CDCA Plan). In October 2012, the BLM issued the *Approved Resource Management Plan Amendments/Record of Decision (ROD) for Solar Energy Development in Six Southwestern States*, which amends the CDCA Plan to include priority areas for utility-scale solar energy ROWs (i.e., SEZs). BLM authorization of a ROW grant for the Project is expected to require a land use Plan Amendment to the CDCA Plan for a short segment of the proposed transmission line, which is located outside of an existing transmission ROW corridor, in conformance with BLM Planning Regulations (43 Code of Federal Regulations [CFR] Part 1600), and BLM Land Use Planning Handbook (H-1601-1). The Plan Amendment process would run concurrently with the NEPA process. Desert Quartzite, LLC recognizes the importance of timely and clear communication with involved public agencies and community stakeholders. Desert Quartzite, LLC will initiate discussions and consultation processes with other involved Federal, State, and local permitting agencies in a timely manner as Project development proceeds. These include the U.S. Fish and Wildlife Service (USFWS), the U.S. Army Corps of Engineers (USACE) and the California Department of Fish and Wildlife (CDFW), and other agencies with potential jurisdiction over the Project in conjunction with the BLM's ROW grant approval process. A formal consultation process under Section 7 of the Federal Endangered Species Act (ESA) will likely take place between USFWS and the BLM with regard to the desert tortoise. Involvement of the USACE with regard to the need for a permit under Section 404 of the Clean Water Act will depend on whether the Corps ultimately chooses to take jurisdiction over drainages or waterways within the Project Site. Section 2.21 of the POD provides detail relating to the Federal, State, and local permits required for the Project.

The construction of the Project will begin once all applicable approvals and permits have been obtained, the necessary transmission upgrades are in place, and a Power Purchase Agreement has been finalized. It is expected to take 18 to 48 months from the commencement of the construction process to complete the Project. Desert Quartzite, LLC's current expectation is that Project construction will begin in late 2015. The Project is planned to be constructed sequentially in two blocks, 150 MW at a time, under separate Notices to Proceed. Once construction is completed, the Project will be in operation for 30 years or more with the possibility of a subsequent repowering of the Project for additional years of operation.

1.4 Proponent's Purpose and Need for the Project

The fundamental purpose of this Project is to construct, operate, and eventually decommission a clean, renewable source of solar electricity that helps meet California's growing demand for power and helps fulfill national and State renewable energy and GHG goals. Solar energy provides a sustainable, renewable source of power that helps reduce fossil fuel dependence and GHG emissions.

The California Energy Commission forecasts that electricity consumption in California will increase by 1.24 percent per year from 2014 to 2024[1]. Peak demand is expected to increase by 1.68 percent annually over

[1] Kavalec, C., Fugate, N., et al. 2013. *California Energy Demand 2014-2024, Revised Forecast, Volume 1: Statewide Electricity Demand, End-User Natural Gas Demand, and Energy Efficiency*. California Energy Commission. CEC-200-2013-004-SD-V1-REV.

the same period. The Project will add 300 MW of renewable generating capacity to California's energy system; in addition, this solar energy will be generated during peak hours of consumption and will help local utilities in meeting increases in peak demand.

This Project will support California in meeting the RPS mandate, which requires California's investor-owned utilities to supply 33 percent of its electricity supply from renewable energy by 2020.

In addition, the Project will help meet the goals set forth in AB 32, which requires that the State's GHG emissions be reduced to 1990 levels by 2020, a roughly 25 percent reduction compared to business-as-usual estimates. Considering the entire process, from raw material sourcing through end of life cycle collection and recycling, the Project's 300 MW of additional generating capacity will produce a tiny fraction of the GHG emissions of a similar capacity fossil fuel power plant.

Federal policy requires government agencies to facilitate the development of renewable energy sources. Executive Order 13212, issued in May 2001, mandates that Federal agencies act expediently and in a manner consistent with applicable laws to increase the "production and transmission of energy in a safe and environmentally sound manner." The Energy Policy Act of 2005 requires the Department of the Interior to approve at least 10,000 MW of renewable energy generation on public lands by 2015. In early 2009, Secretary of Interior Salazar issued Orders 3283 and 3285, making the production, development, and delivery of renewable energy top priorities for the Department of Interior.

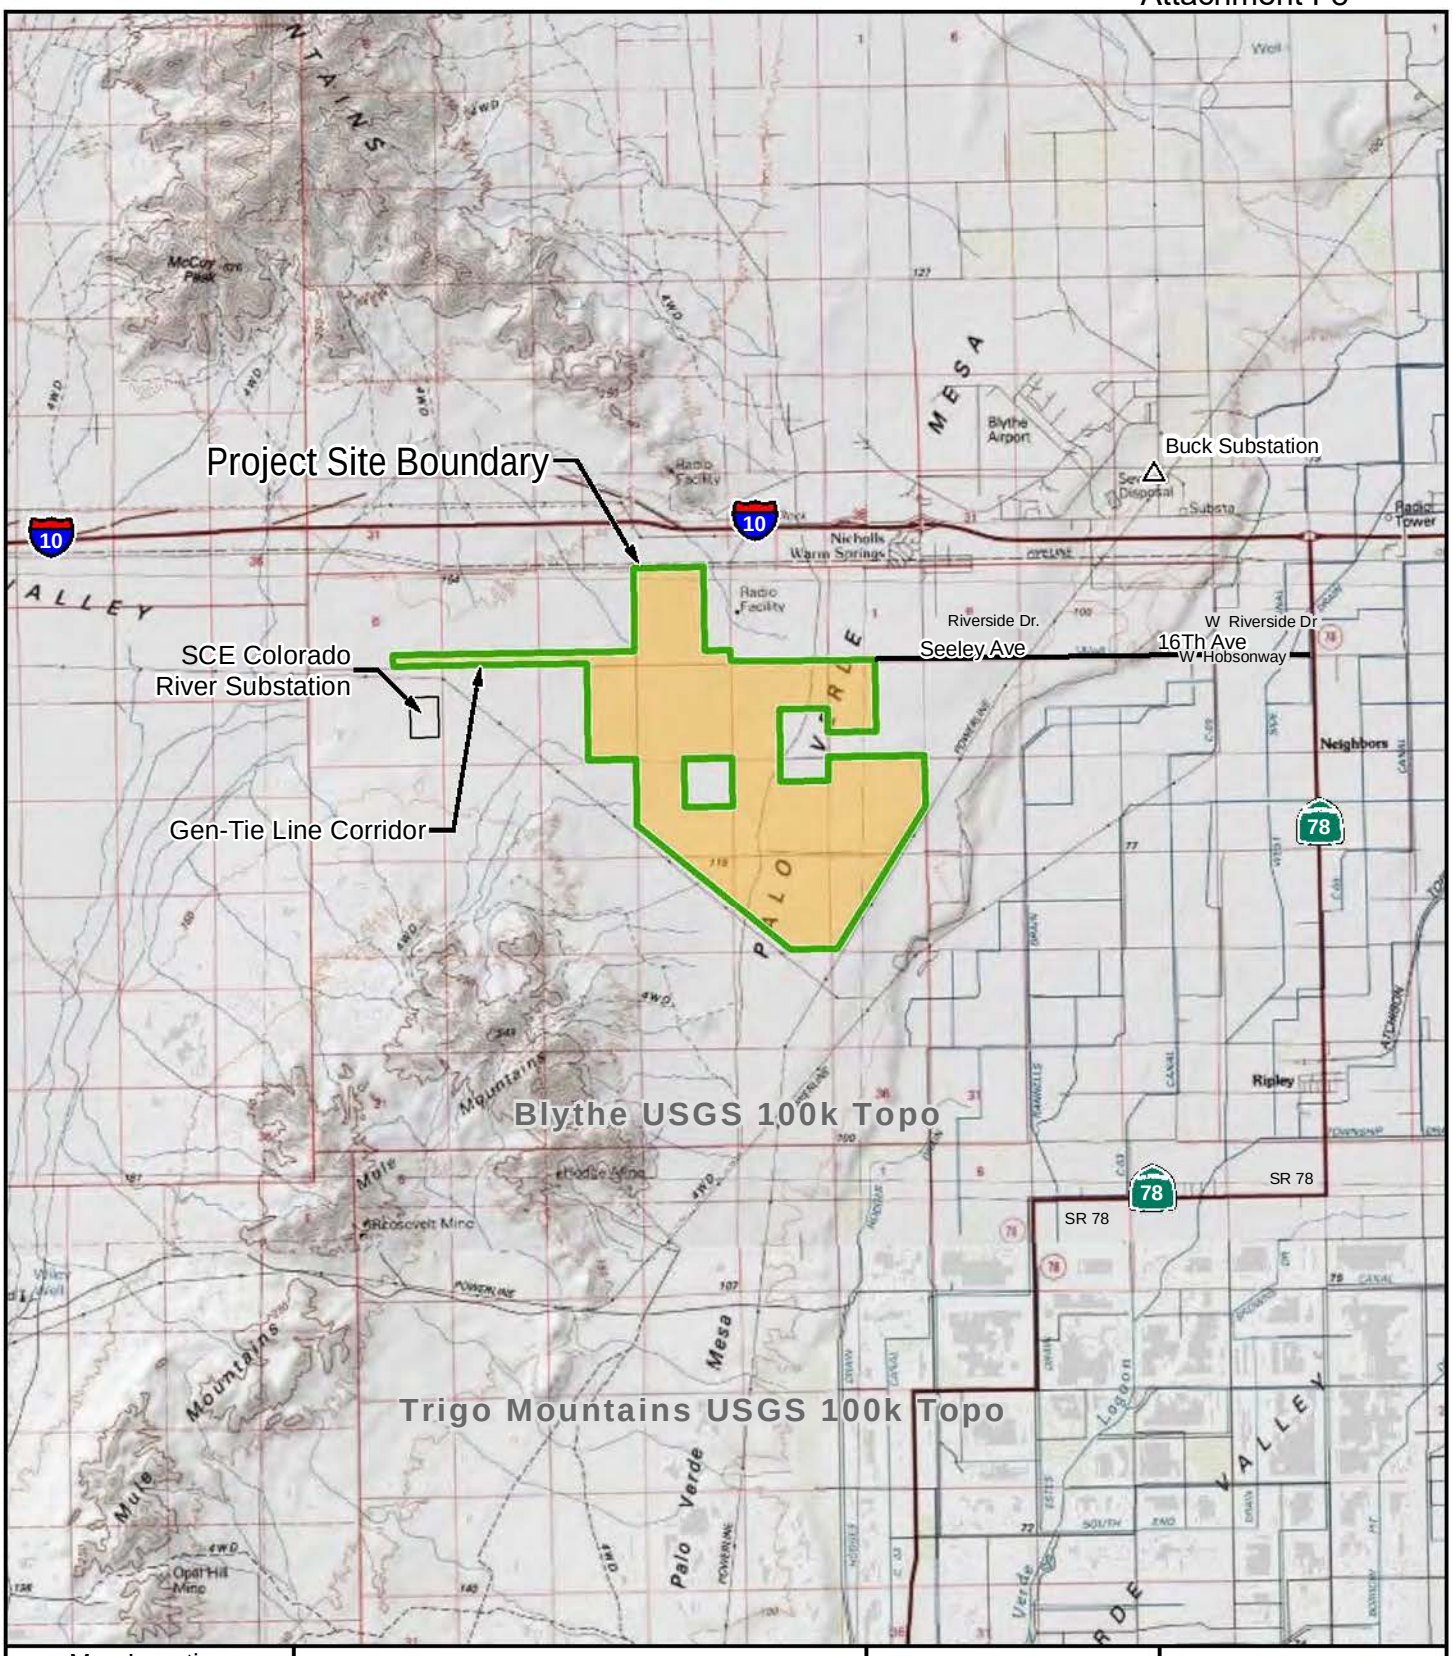
Solar electricity generation is an important component of each of the Federal and State policy goals described above. Among other desirable attributes, the Project site provides excellent solar resource availability and contains lands that are open, generally flat and uniquely situated within a BLM-designated electrical transmission corridor and near existing transmission lines and roadways. The Project Site also is located outside of designated special management areas such as Desert Wildlife Management Areas (DWMAs), Areas of Critical Environmental Concern (ACECs), Critical Habitat Unit (CHUs), and Category I or II desert tortoise habitat (as designated in the NECO Plan). The site is located within the Riverside East SEZ designated in the Solar PEIS prepared by the BLM and U.S. Department of Energy (DOE). The site also is within one of the CREZ identified by California utilities and other stakeholders as part of the ongoing RETI process.

Specific Project objectives are:

- To construct and operate a 300 MW solar PV energy facility using First Solar's proven thin-film PV technology to provide a renewable and reliable source of electrical power to California's investor-owned utilities;
- To locate the Project on contiguous lands with high solar insolation and relatively flat terrain at sufficient scale to maximize operational efficiency while minimizing environmental impacts and water use;
- To minimize environmental impacts and land disturbance by locating the Project in proximity to an established utility corridor and good road access and by avoiding sensitive environmental areas, recreational resources and wildlife habitats (e.g., ACECs, DWMAs, CHUs, Category I and II desert tortoise habitat)
- To assist California and its investor owned utilities in meeting the State's RPS and GHG emission reduction requirements, including the requirements under SB X1-2 to increase the State's RPS to 33 percent renewable power by 2020; and
- To provide community benefits, through new jobs, spending in local businesses, and additional sales tax revenues.

2.0 General Facility Description

2.1 Project Location, Land Ownership, and Jurisdiction



The Project Site is located in eastern Riverside County, approximately 2.75 miles southwest of the western extent of the City of Blythe, California. The Site is just south of Interstate Highway 10 (I-10) and approximately 2.5 miles to the southwest of the Blythe Airport. The community of Nicholls Warm Springs, Mesa Verde is located just to the south of the Blythe Airport, and is the closest town to the Project Site. The town of Ripley is located approximately 4.5 miles to the east. The primary access to the Project Site will be via Interstate 10 (I-10) to State Route 78 (SR 78) to S. Neighborhood Boulevard to 16th Avenue/Seeley Boulevard (see SPP Sheets 2 and 18 [Appendix C]). Secondary access (for limited large loads only) will be provided by I-10 to Mesa Drive to Orange Drive to 16th Avenue/Seeley Avenue, or I-10 to Mesa Drive to Orange Drive to 15th Avenue to Haig Drive to 16th Avenue/Seeley Avenue.

The corridor for the Gen-Tie Line will run generally west from the proposed on-site substation near the northwestern edge of the solar facility Site to the CRSS, located approximately 2.8 miles to the west of the solar facility fenceline.

The overall ROW within which the Solar Facility will be sited and a 600-foot wide study corridor for the Gen-Tie Line are collectively referred to in this POD as the Project Site. A 160-foot-wide ROW for the Gen-Tie Line will be sited within the 600-foot-wide Gen-Tie Line Study Corridor during the environmental review process. Figure 2-1 is a photograph depicting typical conditions within the Project Site Area, and Figure 2–2 shows the Project Site Area, including the 600-foot-wide Gen-Tie Line Study Corridor. As described in this POD, Desert Quartzite, LLC has refined and decreased the study area for the Project Site to exclude the portion south of the DPV transmission lines. The Project Site Area is located on a relatively flat area encompassing approximately 7.6 square miles on the Palo Verde Mesa area of Riverside County. The Palo Verde Mesa region is situated to the north of Mule Mountains; to the east of the Chuckwalla Valley; to the west of the Colorado River; and to the south of the McCoy Mountains and the Big and Little Maria Mountains.

Figure 2-1 Typical View of Project Site Area

Desert Quartzite Solar Project

Figure 2-2 Project Area

Desert Quartzite, LLC

May 2014

AR060636

As mentioned above, the Project Site is on public land administered by the BLM and designated as Moderate (M) Multiple Use Class (MUC). The CDCA Plan MUC Guidelines indicate that solar electrical generation facilities may be allowed in the M MUC.

There is a privately owned parcel in the middle of the Solar Facility ROW, previously the location of a jojoba farm, but this parcel is not part of the requested ROW and will not be part of the Project Site. The Solar Facility will be designed in such a way as to allow for continued access to this parcel.

An existing transmission line, Devers-Palo Verde Line Number 1 (DPV1), traverses from northwest to southeast adjacent to the western boundary of the Project Site, as depicted on SPP Sheet 2 (Appendix C). Figure 2-3 shows the DPV1 line in the vicinity of the Project Site. A second DPV line, Devers-Palo Verde Line Number 2 (DPV 2), has been proposed by Southern California Edison (SCE), just north of and along the same pathway as DPV1 in the Project vicinity, and has been approved for construction in California. The CRSS, the Project's transmission interconnection point, will be located along DPV1 and 2.

Figure 2-3 Devers-Palo Verde 1 Line

In addition to the DPV ROW described above, a number of other easements cross the Project Site. A list of the existing easements is provided in Table 2-1.

In addition to the existing easements discussed in Table 2-1, a 225-foot wide ROW for the planned transmission interconnection route for the Blythe Solar Energy Project crosses the northern portion of the Project Site, running roughly in parallel with the alignment for 16th Avenue (along the southern edge of Sections 3 and 4, T 7S, R 21E).

2.2 Legal Description

A legal description of the Project Site/CACA #049397 is provided in Table 2-2. Figure 2–2 shows the Project Site Boundary in relation to the Public Land Survey System. SPP Sheet 6 (Appendix C) shows the land ownership of the Project Site.

2.3 Project Acreage and Dimensions

As shown on Figure 2–2, the current configuration of the Solar Facility Site and Gen-Tie Line study corridor encompasses the approximately 4,843 acre ROW for CACA # 49397. Within the Solar Facility Site area, the facility footprint (i.e., areas within the fenceline) will occupy approximately 2,453 acres, and the 600-foot-wide Gen-Tie Line study corridor occupies approximately 205 acres. The Gen-Tie Line is approximately 2.8 miles long (portion outside solar facility fenceline up to near northern boundary of SCE Colorado River Substation) and will occur within a 160-foot wide operational ROW corridor occupying approximately 55 acres.

The 600-foot-wide Gen-Tie Line study corridor (205 acres) that is located primarily west of the solar facility boundary consists of substantially more acreage than will ultimately be needed for the Project in order to allow necessary flexibility in adjusting the final routing of the Gen-Tie Line with consideration of environmental conditions to be addressed further in the forthcoming EIS.

2.4 Power Plant Facilities

The Project will involve the installation of First Solar PV modules with the capacity to generate a total of 300 MW of power under peak solar conditions. First Solar has an active Research & Development program that seeks to increase PV module efficiency and design new, more efficient ways to install the PV modules and reduce the footprint of installed energy on a per acre basis. This POD is based on current technology and installation methodology. Inverter hardware will be located in each PCS, which will convert the DC electric input into grid-quality AC electric output.

2.4.1 First Solar Cadmium Telluride (CdTe) PV Technology

The principal materials incorporated into the PV arrays include glass, steel, and various semiconductor metals. First Solar's module production process is designed to minimize waste generation and maximize the recyclability and reusability of component materials. At the end of their useful life, the Project materials will be removed from the site and many will be fully recycled, including the steel tables and posts, wiring, and PV modules themselves.

The First Solar modules used in the Project employ the compound CdTe as the semiconductor material. The unique advantages of CdTe PV technology include:

- Superior light absorption properties, compared to traditional silicon modules, resulting in higher output under cloudy and diffuse light conditions such as dawn and dusk;2
- Better performance at the high temperatures that modules are subject to under direct sunlight compared to traditional silicon modules;3
- Enhanced suitability for production of modules – high volume and low cost;
- Effective sequestration of cadmium in a stable compound between two protective sheets of glass for the lifetime of the module; and
- The smallest carbon footprint and fastest energy payback time of all existing PV technologies.4

Cadmium telluride is a stable compound of cadmium (Cd) and tellurium (Te). Cadmium, Cd, produced primarily as a byproduct of zinc refining, is a human carcinogen as an independent element, but when combined with Te, a byproduct of copper refining, forms the stable, non-hazardous compound CdTe. In module manufacturing, First Solar effectively takes a hazardous material, Cd, and safely sequesters it in the form of CdTe in a module for the over 30-year lifetime of the module, after which it can be recycled for use in new solar modules or other new products. In addition, CdTe's physical properties, including its extremely low vapor pressure and high melting point, along with its insolubility in water, limit its mobility. Furthermore, the very thin layer of CdTe in PV modules is encapsulated between two protective sheets of glass. As a result, the risk of health or environmental exposure in fires, from accidental breakage, or from leaching is de minimus. The exposure routes to CdTe in modules are limited; furthermore, recent toxicological testing indicates that CdTe is significantly less toxic than elemental Cd. First Solar offers an industry-leading collection and recycling program that is designed to recover approximately 95 percent of the semiconductor material and 90 percent of the glass. The remaining materials (e.g., glass fines, dust) are collected in HEPA filters and are disposed of properly. Commercial scale recycling facilities are currently in operation at each of First Solar's manufacturing facilities to recycle materials.

In 2009, an in-depth assessment of the environmental, health and safety aspects of First Solar's CdTe PV systems and manufacturing operations was carried out under the authority of the French Ministry of Ecology, Energy, Sustainable Development, and the Sea. It concluded that, "During standard operation of CdTe PV systems, there are no cadmium emissions – to air, to water, or to soil. In the exceptional case of accidental fires or broken panels, scientific studies show that cadmium emissions remain negligible.

---

M, Alsema, E., "Photovoltaics Energy Payback Times, Greenhouse Gas Emissions and External Costs: 2004 –Early 2005 status," Progress in Photovoltaics: Research and Applications, 2006; 14: 275-280.

Accordingly, large-scale deployment of CdTe PV can be considered safe to human health and the environment."[5]

A 2005 peer review of three major published studies on the environmental profile of CdTe PV organized by the European Commission, Joint Research Center and sponsored by the German Environment Ministry concluded "…CdTe used in PV is in an environmentally stable form that does not leak into the environment during normal use or foreseeable accidents, and therefore can be considered the environmentally safest current use of cadmium." This review also concluded that "Large scale use of CdTe photovoltaic modules does not present any risks to public health and the environment."[6]

Independent analysis also indicates that CdTe modules do not pose a risk during fires. CdTe has an extremely low vapor pressure, high boiling and melting points and is almost completely encapsulated by molten glass when exposed to fire. Exposure of pieces of CdTe PV modules to flame temperatures from 1,400°F to 2,000°F illustrated that CdTe diffuses into glass, rather than being released into the atmosphere. Higher temperatures produce further CdTe diffusion into the glass.[7]

2.4.2 PV Arrays and Combining Switchgear

The Project will be constructed using cadmium telluride thin-film solar modules mounted on single-axis, horizontal tracker structures or fixed-tilt mounting systems, or a combination thereof. The mounting system for the modules is proposed to be supported by steel posts driven into the ground. Based on the general soil and drainage characteristics of the surrounding area, preliminary estimates are that the posts will be driven between 4 and 7 feet into the ground for fixed-tilt structures, and up to 12 feet for tracker structures. Tilt-brackets, which establish the plane of the fixed-tilt arrays (tilt angle), are bolted onto the posts (fixed tilt). Steel table frames (tabletops) are then bolted to the tilt-brackets or tracker structures, and the modules are mechanically fastened to the tables.

If the results of detailed geotechnical investigations indicate that driven steel posts are not an optimal foundation, then other embedded foundation designs may be utilized. Concrete foundations will be required for other Project components, including power conversion stations (PCSs) (which house the inverters), photovoltaic combining switchgear (PVCS) and transformers, weather stations, and substation equipment.

Fixed-tilt arrays, which do not track the sun, are positioned in a south-facing orientation at a tilt between 20 and 25 degrees from horizontal (ground surface) to receive optimal solar energy throughout the year. The rows in each array are oriented in an east-west direction. The maximum height for fixed-tilt arrays is 13 feet above the ground surface for the Ten High System design (see Sheet 7A in Appendix C).

On the single-axis horizontal trackers, the PV modules are mounted horizontally (not tilted to the south). The tracking units are arranged into north-to-south-oriented rows, and are powered by a drive motor to track the east-west path of the sun on a single axis throughout the day. The highest point for a horizontal tracker occurs during the early morning and evening hours and is approximately 13 feet maximum above the ground surface. The tracking systems will be bolted onto posts. If the results of detailed geotechnical

---

[6] Summary Report, "Peer Review of Major Published Studies on the Environmental Profile of Cadmium Telluride (CdTe) Photovoltaic (PV) Systems," European Commission, Joint Research Centre

[7] Fthenakis, V., Fuhrmann, M., Heiser, J., Lanzirotti, A., Fitts, J., and Wang, W., "Emissions and Encapsulation of Cadmium in CdTe PV Modules During Fires," *Progress in Photovoltaics: Research and Applications*, 6, 99-103 (1998).

investigations indicate that driven steel posts are not an optimal foundation, then other embedded foundation designs including concrete footings may be utilized.

These assemblies will be organized into arrays (see Figure 2–4, and SPP Sheet 7 [Appendix C] for typical horizontal tracker details, and Sheet 7A [Appendix C] for typical fixed-tilt configuration details). Placement of arrays within the Project Site will be based on constraints including topography, biological, and geotechnical considerations.

Figure 2-4 Representative Horizontal Tracker PV Array Photograph

The PV modules will be electrically connected by wire harnesses and combiner boxes that collect power from several rows of modules and feed a Power Conversion Station (PCS) (see Figure 2-5 and SPP Sheet 8 [Appendix C]) via underground direct current (DC) cables. Inverter hardware located in each PCS converts the DC electric input into grid-quality alternating current (AC) electric output. A transformer then steps up the voltage of the array output for on-site transmission of the power to the PV Combining Switchgear (PVCS). Overhead lines then take the electricity to the On-Site Substation where the voltage is stepped up and routed to CRSS via the Gen-Tie Line. The PCS and transformer will be located within each PV block, and housed on concrete vaults.

Figure 2-5 Representative Power Conversion Station Photograph

The PVCS (see Figure 2–6) will collect the power from a group of arrays for transmission to the On-Site Substation. The PVCS cabinets will be dispersed amongst the arrays. High-capacity collection system lines will connect the power output from the PVCS to the On-Site Substation. The on-site electrical collection system is designed to minimize electrical losses within the Solar Facility Site prior to delivery to the On-Site Substation.

Figure 2-6 Representative PV Combining Switchgear Photograph

The On-Site Substation facility will be located in an approximately 6.5-acre area located in the northwest portion of the Solar Facility Site. At the On-Site Substation, the voltage of the Solar Facility-generated electricity will be stepped up to interconnect with the SCE regional transmission grid at the CRSS.

2.5 Number and General Dimensions of Project Components

Table 2-3 below provides a list of major Project components along with the approximate acreage they will require. In addition to the PV areas and conversion equipment, which take up the vast majority of the Project acreage, the largest permanent land uses on the Solar Facility Site are access roads, the O&M facility, and the On-Site Substation. Less than one percent of the total footprint will be covered with at-grade facilities (e.g., O&M facility, On-Site Substation, inverter pads), and approximately 50 percent of the Solar Facility Site will typically be covered or shaded by solar modules.

Table 2-3 Solar Facility Components, and Approximate Area[1]

Project Facility or Component	Length or Number of Components	Approx. Area (acres)	Percent of Project Site[2]
Transmission Corridor[3]	2.8 miles (total)	55	1.1
PV Arrays	302	2,896	60%
On-site Project Substation	1	6.5	0.1%
O&M facility	1	5	.1%
Temporary Construction Staging Areas[4]	3	83	1.7%
Access Roads (on-site)[5]	109.9 miles	268	5.5%
Graded Area Including Roads	NA	3,574	73.8%
Area Covered by At-Grade Items (inverter pads, substation, O&M facility)	NA	14.8	0.3%
Area Shaded by PV Modules (at solar noon)	NA	2,226	46%
Area Shaded by PV Modules (scenario-Dec 21, 9:00am)	NA	2,769	57.2%
Total Number of Piles	325,984	0.1	<0.1%
Security Fencing	18.4 miles	NA	NA

[1] Data provided is based on horizontal tracker design which represents worst-case disturbance compared to fixed-tilt designs.

[2] Percentages based on 4,843 acre Project Site (includes 4,660 acre Solar Facility Site, and 183 acre Gen-Tie Line study corridor [600 feet wide]).

[3] Acreage based on a 160-foot transmission ROW width.

[4] Includes three construction staging areas and area for construction offices and parking.

[5] Includes roads (1.1 miles graveled [4.2 acres] and108.8 miles compacted earth/native soil [263.8 acres]) within the Solar Facility Site.

2.6 Temporary Construction Facilities

Included within the Solar Facility Site will be several temporary construction staging areas and an area for construction worker parking. These areas will be utilized throughout the approximately 18- to 48-month Project construction period and then decommissioned and/or replaced by arrays.

The staging areas will include material laydown and storage areas and an equipment assembly area. The Project is not expected to require an on-site cement batch plant. During construction, the area near the location of the O&M facility will also contain a guard shack, construction trailers, construction worker parking and portable toilet facilities that will serve the Project's sanitation needs during construction. Temporary construction fencing will surround this area and the guard shack will be manned to provide security during construction. Refer to SPP Sheet 10 (Appendix C).

Graded all-weather roads will be required in selected locations on the Project Site during construction to bring equipment and materials from the staging areas to the construction work areas, and for long-term Project operation and maintenance. SPP Sheet 18 (Appendix C) shows the locations of the planned access roads. Also see POD Section 3.0, Construction of Facilities.

2.7 Geotechnical Studies

Preliminary geotechnical assessments of the area's soils will be conducted and incorporated into the Project's design. As part of the preliminary geotechnical assessment, a consulting geologist will visit the Project Site to check and evaluate the mapped geologic units and to collect exploratory borings from various locations across the site. Before construction commences, Desert Quartzite, LLC will commission another design-level geotechnical investigation of the Project Site to further explore the consultant's preliminary findings and to determine the best foundation types for the Project structures and facilities.

According to Natural Resources Conservation Service (NRCS) information, soils within the Project area vary across the site and consist of gravelly loamy sands, sandy loam, gravelly sands, and fine sands. Refer to Appendix D, Figure 4, showing the NRCS soil types within the Project Site. A map of surface geology within the Project Site is included as SPP Sheet 13 (Appendix C).

A Preliminary Geotechnical Investigation Report (URS 2011) (based on literature review) is presented in Appendix D of this POD. The Preliminary Geotechnical Investigation Report findings indicate that geotechnical-related conditions and constraints at the Site can be mitigated through field investigation and appropriate design measures.

2.8 Ancillary Facilities

2.8.1 Operations and Maintenance Facility

The Operations and Maintenance (O&M) facility, located adjacent to the On-Site Substation, will be designed for parts storage, plant security systems, and Project monitoring equipment. The O&M facility will consist of offices, a restroom, and a storage area. A septic system and leach field will be located at the O&M building, as shown on SPP Sheet 9 (Appendix C), and will serve the Project's sanitary wastewater treatment needs.

2.8.2 Meteorological Station

One or more meteorological stations will be installed prior to construction in order to track weather patterns. Figure 2-7 depicts a typical meteorological station. The meteorological station(s) will be attached to the data acquisition system (DAS) to collect data for analysis and system monitoring. The DAS involves a network of data loggers and programmable logic controllers at each PCS enclosure. These will, in turn, be connected

to a Wide Area Network and monitored on-site in the O&M facility, as well as in a remote Network Operations Center.

Figure 2-7 Typical Meteorological Station Photograph

2.8.3 Anemometers

Anemometer towers, which measure and communicate wind speed data to the facility control room for solar array panel tracker positioning in the event of high winds, would be installed around the site perimeter. Each tower would typically measure approximately 20 feet in height, but could range up to 30 feet maximum.. An estimated 9 anemometer tower structures are currently proposed as part of the proposed Site layout (refer to SPP Sheet 3 in Appendix C for locations). Refer to Figure 2-8 showing a typical tracker anemometer tower.

Figure 2-8 Typical Tracker Anemometer Tower Photograph

2.8.4 Other Ancillary Facilities

A guard shack will be constructed at the entrance to the Project Site for use by security personnel during Project construction and operations phases. It is expected that the guard shack will be manned 24 hours a day throughout the construction phase of the Project.

2.9 Water Uses and Sources

2.9.1 Groundwater Setting

The Project Site is located in the northwestern Colorado Desert, which is part of the greater Colorado Desert Geomorphic Province. The Colorado Desert Geomorphic Province is characterized by isolated mountain ranges separated by broad alluvium-filled basins of Cenozoic-age sedimentary and volcanic materials overlying older rocks. Much of the Colorado Desert lies at low elevations, with some areas below sea level.

The Project Site is located in the alluvial-filled basin of the Palo Verde Mesa in eastern Riverside County, California, approximately 2.75 miles west of the western border of the City of Blythe. Beneath the Palo Verde Mesa lies the Palo Verde Mesa Groundwater Basin (PVMGB), which is bounded by non-water-bearing rocks of the Big Maria and Little Maria mountains to the north, the McCoy and Mule Mountains to the west, and the Palo Verde Mountains to the south. The Big Maria Mountains and the McCoy Mountains are the contributing watersheds to the Palo Verde Mesa. The groundwater storage capacity is estimated at 6,840,000 acre-feet (AF) with the groundwater in storage currently unknown[8]. It is likely that recharge of the basin is primarily from percolation of runoff from the surrounding mountains, and percolation of precipitation to the valley floor and subsurface inflow may be additional sources of recharge (DWR 2004). Natural recharge in the basin is estimated at about 800 acre-feet per year (AFY), and recharge by underflow from Chuckwalla Valley is estimated to be 400 AFY[9].

The groundwater movement is southeasterly to the Palo Verde Valley[10]. It is observed from surface conditions that groundwater elevations would decrease in a southeasterly direction to ultimately outfall in an agricultural drain to the east of the Project Site[11].

The project is located in the Riverside East SEZ, which contains portions of the Chuckwalla Valley and Palo Verde Mesa groundwater basins and covers approximately 150,000 acres along an east-west corridor along I-10 between the towns of Desert Center and Blythe. A recent groundwater model was assembled for the BLM to assess the potential impacts of groundwater pumping within the Riverside East SEZ associated with full build out of utility scale solar projects within the SEZ[12]. The intent is that this model be updated as large scale solar projects are initiated.

2.9.2 Project Water Supply and Water Usage

Construction water usage rates and total requirements would vary depending on the length and intensity of construction activities. The construction timeframe is estimated to vary from 18 to 48 months. Although an 18-month construction timeframe (minimum) is much shorter than a 48-month construction timeframe (maximum), the Project's water needs are directly related to the intensity of construction activities such as water for fugitive dust control and soil compaction associated with site preparation and grading activities. It is currently estimated that the maximum water usage for an 18-month construction timeframe would total

---

[8] California Department of Water Resources (DWR). 2004. California's Groundwater – Bulletin 118. Basin Descriptions: Palo Verde Groundwater Basin. (http://www.water.ca.gov/pubs/groundwater/bulletin_118/basindescriptions/7-39.pdf)

[9] Ibid.

[10] Ibid.

[11] Stone and Webster Engineering Corporation. 1976. Evaporation Basin Report, SunDesert Nuclear Plant, San Diego Gas & Electric Company, San Diego, California. June.

[12] Argonne National Laboratory. 2013. A Groundwater Model to Assess Water Resource Impacts at Riverside East Solar Energy Zone. ANL/EVS/R-13/8. December.

about 1,300 acre feet (AF)(i.e., approximately 867 AF per year on average) whereas a 48-month construction timeframe would require a maximum total of approximately 1,800 AF (i.e., approximately 450 AF per year on average). During construction, water will be needed for primarily dust control and soil compaction, with small amounts used for sanitary and other purposes.

During operations, the Project will use no water for electricity generation. The operational phase of the Project is expected to require up to 38 AFY of water. Of this volume, approximately 20 AFY would be used for process water, fire protection, dust control, vegetation management, and at the O&M building, and 18 AFY would be used for up to two annual panel washings. This annual demand during Project operation is a small fraction of the most recent California Energy Commission information for a similar-sized solar thermal generation facility. An aboveground process water/firewater storage tank will be included on the site, as shown on SPP Sheet 9 (Appendix C). The tank size and dimensions will be determined based on Riverside County Fire Department requirements for firewater storage.

Although a water supply investigation has not yet been conducted for the Project, Desert Quartzite, LLC plans to utilize groundwater from either existing local well(s) or via installation of two groundwater wells (one temporary and one permanent) as the water supply source for the Project during both construction and operations. A study will be performed to establish the feasibility of obtaining the needed supplies either from groundwater well(s) developed on the Project Site or from existing groundwater wells that may be identified in the immediate vicinity. In the event that new wells are to be installed on-site, one permanent well would be installed at the O&M facility area. Refer to SPP Sheet 9 (Appendix C) showing the permanent well location and associated water line (on-site only) to the proposed aboveground water storage tank. One temporary construction well would be installed in the southeast or southwest portion of the site (refer to SPP Sheet 3 [Appendix C] for well locations).

Although no site-specific data has yet been obtained, Desert Quartzite, LLC is considering use of local groundwater because of its recent experience in constructing a 21-MW PV project in the near vicinity (i.e., adjacent to the Project Site to the north) of the Project Site. For the 21-MW project (now owned and operated by NRG Solar), adequate water supply for construction was successfully obtained from an on-site well. Given the proximity of the two sites, this suggests that local groundwater may be feasible for Project use. However, as noted, additional study is needed to determine whether this is a viable option.

If Desert Quartzite, LLC decides to install a groundwater well or wells on the Project Site, Desert Quartzite, LLC will perform the necessary studies and secure the necessary permissions to install the well(s). An analysis of impacts of Project water consumption on water availability in the Palo Verde Groundwater Basin will be conducted as part of the EIS process.

2.10 Hydrological Conditions

A hydrological study (drainage report) of the proposed Project Site has been completed and is presented in Appendix E of this POD. The 2011 hydrological study considered the current site boundary, but with a smaller facility footprint. The study includes the results of a hydrologic analysis and hydraulic model of the Site for existing (i.e., pre-Project) conditions. The study includes the results of a watershed analysis that encompasses areas immediately upstream and downstream of the Site to determine and evaluate the Site's potential peak flows and off-site peak flows during 100-year storm event. The preliminary results of the hydrologic and hydraulic modeling of storm water flow rates and sediment transport rates will be considered in the final Project design. The conclusions in the 2011 Drainage Report are presented in Section 7.1.3 and Appendix E.

The Project is located in an existing drainage alluvial fan area which receives drainage from off-site mountains and off-site alluvial fan areas. The off-site downstream areas consist of alluvial fan areas with drainage flows that ultimately drain over bluffs east of the Project Site.

There are two mountain areas that drain into and through portions of the Project Site; sediment from these areas created the alluvial fan area that occupies the Project Site. One area is north of I-10. This shed consists of a portion of the McCoy Mountains and a portion of an alluvial fan that has been blocked and diverted to the southeast by channelization and I-10. This shed consists of 3,343-acres and ranges in elevation from 1,670 feet above mean sea level (amsl) at the northwest corner to 470 feet amsl at the I-10 bridge crossing. The area drains under an I-10 bridge into an area south of the I-10 bridge and into the alluvial shed area in and around the northern portion of the Project Site.

The other mountain area is towards the southwest side of the Project Site. These sheds consist of a portion of the Mule Mountains that drain into the alluvial fan area in and around the western portion of the Project Site. These sheds have a cumulative acreage of 2,043-acres and range in elevations from 1,750 feet amsl to 395 feet amsl where they enter into the alluvial fan.

The alluvial fan drainage area studied consists of the off-site and on-site areas in the Palo Verde Mesa. The area consists of 15,695 off-site acres and an assumed 4,769 Project on-site acres for a total of 20,464-alluvial fan acres. The total alluvial fan area ranges in elevation from the highest elevation in the northwest of 525 feet amsl to a lowest elevation of 320 feet amsl in the southeast. The straight line length between these elevations is approximately 6.92-miles and yields a slope of 0.0056 feet/foot.

The area is undeveloped except for the First Solar-constructed, 200 acre, 21 MW, NRG-owned solar project abutting the northeast side of the Project; a portion of a developed subdivision located south of I-10 at the northeast side of the drainage shed studied; and overhead power line facilities that cross the drainage sheds studied. There are some areas in the alluvial fan area south of I-10 that were cultivated in the past but are currently not active. There also are some bermed areas in the alluvial fan that have evidently been constructed to divert drainage flows away from the internal areas protected by the berms. One of these bermed areas consists of a 160-acre parcel (previously used as a jojoba farm) near the middle of and completely surrounded by the proposed Project. The Project does not propose removal or disturbance of any existing berms.

2.11 Site Preparation, Erosion Control, and Storm Water Drainage

First Solar (EPC contractor) would utilize site preparation techniques that adequately prepare the site for safe and efficient and operation of PV arrays while allowing water to sheet flow across the Site with negligible impact on surface water flow upstream and downstream of the Site. The planned approach to Project Site preparation, which involves the use of “disc and roll” and micrograding techniques, reflects the results of the First Solar’s field testing of various site preparation techniques at an off-site location near the Project Site, as well as their experience with construction of similar solar PV projects in other desert locations in Southern California and Nevada. First Solar has been using this experience to adjust and optimize its site preparation and construction methods.

Based on the hydrologic evaluation described in Section 2.10, the Applicant will implement site design and protective erosion and drainage control design measures during construction and operation to achieve the above objectives. Storm water flow will be managed to prevent downstream erosion and channelization.

Contour grading, erosion control design features, storm water mitigation measures and other protective measures (including avoiding the placement of PV module tables and piles within significant drainages and minimizing disturbance and compaction to the extent possible), will enable historic levels of runoff off-site to be maintained at the Project Site and in downstream areas.

SWPPPs would be prepared as applicable to discharges to Waters of the U.S. The Applicant will design erosion control plans and implement SWPPP Best Management Practices (BMPs) under the direction of a Qualified SWPPP Practitioner (QSP) for storm water management and control. Preliminary erosion control

BMPs are shown on Sheets 16 and 17 in Appendix C. The BMPs to be implemented would manage storm water on the site to both protect the site and to minimize downstream erosion and sedimentation.

Several erosion control measures are planned during construction including stabilization of the heavily-used construction entrance area, employing a concrete wash-out area, as needed, and tire washes near the entrance to existing roadways. Silt fences are proposed for erosion control along neighboring properties.

The approximate percentage of the Project Site that will be covered with impervious surfaces (inverter foundations, etc.) will constitute a fraction of one percent of the total surface area of the Project Site. The final Site Plan will be based on a detailed topographic survey of the Project Site, as well as detailed hydrologic and topographic studies that will be performed as a part of the permitting and engineering design process. A Project Drainage Shed Map is shown on SPP Sheet 11 (Appendix C). No Federal Emergency Management Agency- (FEMA-) designated flood zones exist within the vicinity of the Project; the Project Site Area and vicinity are classified by FEMA as Zone D – Not Studied (see FEMA Flood Hazard Map, SPP Sheet 12, Appendix C).

2.12 Vegetation Treatment and Weed Management

Desert Quartzite, LLC will develop a plan for vegetation management at the Project Site. Desert Quartzite, LLC will coordinate with the BLM, USFWS, and CDFW to determine the best methods and species to employ in the vegetation plan. Further details relative to this vegetation management plan will be provided during the NEPA process. An Integrated Weed Management Plan also will be developed and implemented to control invasive exotic weeds. The plan will comply with existing BLM plans and permits including the *Vegetation Treatments Using Herbicides* (2007) and *Vegetation Treatment Final EIS* (2007).

2.13 Waste and Hazardous Materials Management

The Project will generate minimal wastes during operation. There also will be limited amounts of chemicals and petroleum products stored or used on-site as shown in the tables below. A Spill Prevention, Control, and Countermeasure (SPCC) Plan will be implemented during operation, as required. Appropriate spill containment and clean-up kits will be kept on-site during construction and maintained during the operation of the Project. The primary chemicals/petroleum products expected to be present on the Project Site during construction and operation are listed in Table 2-4 and Table 2-5, respectively.

Table 2-4 Chemicals at Project Site During Construction

Product	Use
Diesel Fuel	Vehicles
Gasoline	Vehicles
Motor Oil	Vehicles
Hydraulic Fluids and Lube Oils	Vehicles and Equipment
Solvents and Adhesives	PV Module Assembly
Soil Stabilizers	Roads and PV Table Areas

Table 2-5 Chemicals at Project Site During Operation

Product	Use
Diesel Fuel	Vehicles
Gasoline	Vehicles
Motor Oil	Vehicles

First Solar PV modules and other products used during construction and operation of the Project are generally not hazardous and are not subject to Federal hazardous material management regulations. First Solar's end-of-life CdTe PV modules are currently characterized as federal non-hazardous waste, and as a California-only hazardous waste. Solar equipment and infrastructure will be recycled as practical or disposed of in compliance with applicable laws. Electrical generating activities will not produce hazardous or other industrial waste. Desert Quartzite, LLC will utilize biodegradable oil in transformers rather than mineral oil.

During construction of the Project, the only wastes produced will be typical construction wastes, such as broken PV modules, wood, concrete, and miscellaneous packaging materials. Construction wastes will be disposed of in accordance with local, State and Federal regulations. Any modules damaged or broken during construction are considered retrograde material and will be returned to First Solar's manufacturing facility in Ohio, where they will be recycled into new modules or other new products (also see Section 2.14 below).

Portable toilets will be used during construction and will be regularly pumped out, hauled away, and disposed of by appropriately licensed organizations. An on-site septic system and leach field near the on-site O&M facility will be used to manage sanitary waste during Project operation. Because of the small operational work force (up to 15 full time workers), volumes of sanitary waste discharged to the septic system and leach field will be no more than a few hundred gallons per day during operation.

Permits for the septic system will be obtained from Riverside County, as needed. Soil percolation tests will be performed in order to demonstrate that an on-site septic system and leach field is feasible at the planned location. Additional testing may be performed in accordance with Riverside County test procedures prior to final leach field design. The specific location of the leach field and septic system may be adjusted based on the results of preliminary percolation tests.

2.14 Reusable and Recyclable Materials/PV Module Recycling

As discussed in Section 2.13, the PV modules and inverters would produce no waste during operation of the proposed solar facilities. However, end-of-life PV modules are considered to be a California-only hazardous waste. Solar equipment and infrastructure will be recycled as practical or disposed of in compliance with applicable laws. The PV module manufacturer (First Solar) offers CdTe module collection and recycling services. The PV module manufacturer pioneered the first global and comprehensive module collection and recycling program in the PV industry in 2005. The Project facilities include numerous recyclable materials, including glass, semiconductor material, steel, and wiring. As the Project approaches the end of its useful life, the component parts will be dismantled and recycled, as practical. First Solar offers a pre-funded recycling program for all of its solar modules as described in the following paragraphs.

As manufacturer and supplier of the PV modules to the Project, First Solar is committed to the philosophy of extended product responsibility and to improving the global environment, and as such offers a Collection and Recycling Program to promote the collection and recycling of PV modules. The program enables

substantially all components of the modules, including the glass and the encapsulated semiconductor material, to be collected and recycled into new modules or other products.

Under this program, First Solar offers its customers the ability to set aside funds, at the time of module sale to meet estimated collection and recycling costs, including all packaging, transportation, and recycling costs. Some key elements of the First Solar recycling Program include:

- Funding: With the sale of each module, First Solar sets aside the funds required for the collection and recycling in a restricted account controlled by a third-party insurance company;
- Registration: The site location of each module installation is registered with First Solar;
- Notice: Individual modules are labeled with Web site and telephone contact information in six languages, along with instructions for the user to return the product free of charge;
- Collection: First Solar manages the logistics of collecting each module and provides packaging and transportation to the recycling center;
- Recycling: All recycling processes are monitored to ensure compliance with local regulations regarding health, safety, and waste management; and
- Improvement: Results of the program are audited for continuous improvement.

Managing the product lifecycle, from raw material sourcing through end-of-life collection and recycling, enables First Solar to create a perpetually sustainable cycle that strives to provide the most environmental benefits.

2.15 Fire Protection

There is limited potential for wildfire on the Project Site. The Project is not located adjacent to either urbanized areas or wild lands. Vegetation is sparse and the facility footprint itself will be cleared, so that fire risk from vegetation will be minimized. The Project will coordinate with Riverside County to ensure that appropriate measures will be taken to control the risk of fire. During operations, one aboveground water storage tank will be installed adjacent to the O&M facility. The tank will be sized to meet Riverside County Fire Department requirements to supply sufficient fire suppression water during operations. Additional fire protection measures will include: sprinkler systems in the O&M building; a FM200 fire suppression system, or equivalent, in the facility control room at the O&M building; and portable carbon dioxide (CO_2) fire extinguishers mounted at the power conversion system units.

Project facilities will be designed, constructed, and operated in accordance with applicable fire protection and other environmental, health and safety requirements. Effective maintenance and monitoring programs are vital to productivity as well as to fire protection, environmental protection, and worker protection.

Desert Quartzite, LLC will have a Project fire prevention plan in place for construction and operation. This plan will comply with applicable Riverside County regulations and will be coordinated with the Riverside County Fire Department. During construction, the following steps will be taken to identify and control fires and similar emergencies:

- Electrical equipment that is part of the Project will only be energized after the necessary inspection and approval, so there is minimal risk of any electrical fire during construction.
- Project staff will monitor fire risks during construction and operation to ensure that prompt measures are taken to mitigate identified risks.
- Transformers located on-site will be equipped with coolant that is non-flammable, biodegradable and contains no polychlorinated biphenyls or other toxic compounds.

2.16 Site Security and Fencing

The proposed Project Site boundary, which excluding the off-site Gen-Tie Line study corridor encompasses approximately 4,660 acres,will be fenced to facilitate Project and equipment security. Within the Project Site area, the facility area contained within the fenceline would occupy approximately 3,516 acres. Security at the Project Site will be achieved by fencing, lighting, security patrols, and electronic security systems. The Project Site will be monitored on a 24-hour-per-day, 7-day-per-week basis. Site security will be provided through a combination of on-site staffing and security patrols, remote monitoring, or electronic security systems. Surveillance methods such as security cameras, motion detectors, or heat sensors may be installed at locations along the Project boundary. Gates will be installed at the roads entering or exiting the Solar Facility Site. Limiting access to the Project will be necessary both to ensure the safety of the public and to protect the equipment from potential theft and vandalism. The perimeter of the Solar Facility Site will be fenced with an approximately six-foot tall chain-link fence topped with barbed wire for security purposes. In addition, six-foot chain-link fencing will surround the Project's on-site substation, switching station, O&M facility, and the temporary construction staging areas. The perimeter fence will include tortoise exclusion fencing, as appropriate, to prevent desert tortoises from entering the Solar Facility Site. Refer to SPP Sheet 19 (Appendix C). The Solar Facility Site will be designed, operated, and maintained so that channelization will not occur under the desert tortoise fencing which could undermine its integrity as exclusion fencing.

Shielded area-specific lighting for security purposes will be limited to the O&M facility, the On-Site Substation, the temporary construction staging areas, and possibly on or near each PCS station. The level and intensity of lighting will be the minimum needed for security and safety reasons. These lights will be turned on either by a local switch, as needed, or by motion sensors that will be triggered by movement at a human's height during maintenance or emergency activities. In order to minimize the Project's visual impact on surrounding receptors and roads, there will be no lights around the Project perimeter. Sensors on the security fencing will alert security personnel of possible intruders. Exterior lights will be shielded and focused downward and toward the interior of the site to minimize lighting impacts to the night sky and neighboring areas.

2.17 Electrical Components, New Equipment, and Existing System Upgrades

An On-Site Substation (owned and operated by Desert Quartzite, LLC) will be constructed in the northwestern portion of the Solar Facility Site. As shown on Figure 2–2 and SPP Sheet 3 (Appendix C), the Project's Gen-Tie Line will run north from the On-Site Substation and then turn to the west along the planned utility corridor that crosses the Project site in an east- west direction along the 16th Avenue alignment. The Project Gen-Tie Line runs primarily in a western direction approximately 2.8 miles from the Solar Facility fenceline until it reaches the proposed CRSS. The Project's electrical transmission system is discussed further in Section 4.1, below.

2.18 Interconnection to Electrical Grid

Interconnection to the CAISO Grid via the SCE-operated transmission system will be at the CRSS. The Project's electrical transmission system is discussed further in Section 4.1, below.

2.19 Spill Prevention and Containment

A SPCC Plan will be implemented during operation, as required. BMPs will be employed in the use and storage of all hazardous materials within the Project, including the use of containment systems in appropriate locations. Appropriately sized and supplied spill containment kits will be maintained on-site in the O&M area, and Desert Quartzite, LLC employees will be trained on spill prevention, response, and containment procedures. In addition, in accordance with the Emergency Planning & Community Right to Know Act, Desert Quartzite, LLC will supply the local emergency response agencies with a Hazardous Materials Management Plan and an associated emergency response plan and inventory.

The small quantities of chemicals to be stored at the Solar Facility Site during construction include equipment and facilities maintenance chemicals such as those listed in Table 2-4. These materials will be stored in their appropriate containers in an enclosed and secured location such as portable outdoor hazardous materials storage cabinets equipped with secondary containment to prevent contact with rainwater. The portable chemical storage cabinets may be moved to different locations around the site as construction activity locations shift. The chemical storage area will not be located immediately adjacent to any drainage. Disposal of excess materials and wastes will be performed in accordance with local, State and Federal regulations; excess materials/waste will be recycled or reused to the maximum extent practicable.

Additional construction period BMPs will include:

- Keeping materials in their original containers with the original manufacturer's label and resealed when possible;
- Avoiding excessive on-site inventories of chemicals; procure and store only the amounts needed for the job;
- Following manufacturer's recommendation for proper handling and disposal;
- Conducting routine inspections to ensure that all chemicals on-site are being stored, used, and disposed of appropriately;
- Performing timely maintenance on vehicles/equipment that are leaking oil or other fluids, and placing drip plans under the leak when the vehicle/equipment is parked prior to the maintenance event;
- Performing fueling of vehicles and equipment in locations that are protected from spillage onto exposed ground surface:
- Ensuring that all personnel dealing with hazardous materials are properly trained in the use and disposal of these materials in accordance with local, State and Federal regulations;
- Maintaining Material Safety Data Sheets available on the site for use during Project construction and operation.

As noted earlier in Section 2.13, the Project will not involve the use or storage of large quantities of chemicals compared to other large industrial facilities. Facilities will be appropriately designed and as previously described, a SPCC Plan will be prepared if needed.

Spill response plans will be developed prior to Project construction and operation, and personnel will be made aware of the procedures for spill cleanup and the procedures to report a spill. Spill cleanup materials and equipment appropriate to the type and quantity of chemicals and petroleum products expected will be located on-site and personnel shall be made aware of their location. Key employees will be trained in conducting spill response activities in accordance with appropriate procedures. Spill response materials will include, but are not limited to, brooms, dust pans, mops, rags, gloves, absorbent pads/pillows/socks, sand/absorbent litter, sawdust, and plastic and metal containers.

2.20 Health and Safety Program

First Solar has established "Safety First" as a core value. Safety First is included in all aspects of manufacturing and for engineering design, procurement and construction of a solar array project. First Solar will develop an Environmental Health and Safety Plan in conjunction with Desert Quartzite, LLC to ensure it includes all activities and compliance to all local, State and Federal regulatory requirements. The plan is customized as needed for the specific project based on location, scope and hazards. The Project will comply with all Occupational Safety and Health Administration (OSHA) and California OSHA (CalOSHA)

requirements in construction and operation. Illness and Injury Prevention Programs will be developed for construction and operation. For construction activities, all subcontractors are screened to review their safety performance. Safety orientation will be provided to all contractors working on the site to make them aware of all the project safety hazards and requirements and procedures. Tool box safety meetings will be held daily to discuss site conditions, pre-task plans and any new hazards.

First Solar's manufacturing processes include comprehensive and conservative environmental health and safety (EHS) protocols and processes. First Solar has full time Environmental Health and Safety resources working to ensure a safe work environment and compliance to all EHS regulations and standards. First Solar uses state of the art engineering controls, operational procedures, housekeeping methods, and personal protective equipment to ensure the health and safety of employees as well as the community. First Solar has integrated environmental responsibility into every aspect of the product lifecycle. From raw material sourcing through end of life collection and recycling, First Solar has created a sustainable cycle that protects and minimizes impacts to the environment. The Perrysburg, Ohio, manufacturing facility is certified to OSHA's 18001 for Health and Safety Management Systems and ISO14001:2004 environmental standards. Manufacturing in Germany and Malaysia are certified to ISO14001:2004 environmental standards.

2.21 Other Federal, State, and Local Agency Permit Requirements

2.21.1 Federal Permits and Status

Table 2-6 provides a list of the Federal permits anticipated to be required for the Project, as well as the status of relevant permit applications.

Table 2-6 Status of Project Federal Permits and Authorizations

Permit	Lead Agency	Status
FLPMA ROW Grant	BLM	The original FLPMA Standard Form 299 ROW application was submitted to BLM in September 2007. The original POD was submitted in November 2008, revised in August 2010, and revised most recently as of September 2011. This POD is an update to the September 2011 POD. On December 13, 2013 First Solar submitted a letter amendment of the filing area boundary and change of applicant from First Solar to Desert Quartzite, LLC. The ROW Grant is subject to NEPA review and terms and conditions as set forth under FLPMA and BLM's implementing regulations. BLM will issue a ROW grant and Record of Decision (ROD) at the end of the NEPA process.
BLM ROW Permits	BLM, Palm Springs – South Coast Field Office	Desert Quartzite, LLC will apply for and obtain applicable BLM ROW Permits for pre-construction activities involving vegetation/ground disturbance and/or subsurface excavations such as for geotechnical field investigations, groundwater monitoring well installation, and meteorological tower placement.

Table 2-6 Status of Project Federal Permits and Authorizations

Permit	Lead Agency	Status
Section 404 Clean Water Act (CWA) Permit	U.S. Army Corps of Engineers (USACE)	Desert Quartzite, LLC will conduct a delineation to determine if any of the ephemeral washes on-site are subject to Federal jurisdiction under the CWA. Desert Quartzite, LLC will seek concurrence with this delineation from the USACE and obtain a Section 404 permit, if required. Based on a preliminary biological resources assessment, it is expected that most of the washes on-site will not be jurisdictional under the CWA (see POD Section 6.1.3).
Endangered/Threatened Species Consultation and Incidental Take Statement under the Federal ESA	USFWS	Desert Quartzite, LLC and the BLM will engage the USFWS in the ESA Section 7 consultation process concurrently with the NEPA review process and will obtain incidental take statement authority, as necessary. Informal meetings, e-mail discussions, and phone calls will be conducted to streamline this process by familiarizing USFWS with the Project and eliciting agency concerns to be addressed throughout the process. Biological surveys for federally-listed species for the Project Site are in progress.
Bald and Golden Eagle Protection Act Permit	USFWS	Based on site conditions, the Project Site does not support nesting habitat for golden eagles, but is suitable for foraging by this species. Suitable nesting habitat may be present in the nearby mountainous areas south and west of the site. Desert Quartzite, LLC will coordinate with the BLM and USFWS to determine what effects on golden eagles are likely to result from Project-related losses of foraging habitat. If it is determined that the loss of foraging habitat would be likely to result in the "take" of golden eagles by precipitating decreases in eagle productivity, Desert Quartzite, LLC will obtain the required take permit from the USFWS.
National Historic Preservation Act Section 106 Compliance	BLM	Desert Quartzite, LLC will conduct cultural resources investigations for the Project's Area of Potential Effects. BLM will initiate consultation with the State Historic Preservation Office after Class I and Class III cultural resource inventories have been completed and approved. Section 106 compliance requirements will be met prior to the completion of NEPA analysis.
Archaeological Resources Protection Act, Cultural Resource Use Permit	BLM, State Office	As required based on the planned cultural resources investigations, a BLM Cultural Resource Use Permit will be obtained for the purposes of testing to determine the National Register of Historic Places significance of identified sites and to conduct data recovery on sites adversely affected by project construction and operation.

Table 2-6 Status of Project Federal Permits and Authorizations

Permit	Lead Agency	Status
Fieldwork Authorization	BLM, Palm Springs-South Coast Field Office	A BLM Fieldwork Authorization will be obtained prior to conducting Class III cultural resource inventories.
Native American Consultation	BLM	Desert Quartzite, LLC will coordinate with BLM to support BLM's consultation with Native American tribes for the purpose of identifying sacred sites and other places of traditional religious and cultural importance. Consultation with tribes will continue throughout the NEPA and Section 106 compliance processes.
CDCA Plan Amendment	BLM	The Project Site is located within the boundaries of the area administered under the NECO Plan, an element of the CDCA Plan. The Project will require a CDCA Plan Amendment (e.g., to address utility corridor encroachments and roads) to address the segment of the proposed gen-tie line located outside of the existing transmission ROW. The Plan Amendment will be addressed as part of the FLPMA and NEPA processes as provided for in the BLM Planning Regulations (43 CFR Part 1600), and BLM Land Use Planning Handbook (H-1601-1).
Department of Defense (DoD) Review	DoD	Desert Quartzite, LLC will request a review of the project by DoD for its potential impact on military overflights and operations.
Bureau of Reclamation Coordination for Draft Groundwater Accounting Surface	Bureau of Reclamation (USBR)	Desert Quartzite, LLC will request coordination with USBR regarding the draft Groundwater Accounting Surface, as applicable, following completion of further groundwater study and analysis for the potential Project drawdown

As described in Table 2-6, the Project, which is located on BLM-administered lands, will require a FLPMA ROW grant, thereby triggering the need for NEPA review. BLM will prepare an EIS to comply with NEPA. BLM will issue the necessary ROW grant through its ROD following completion of the Final EIS. The CDCA Plan Amendment required for the Project transmission line will also be addressed through the FLPMA and NEPA process.

Based on biological resources research conducted to date, Desert Quartzite, LLC expects there may be potential impacts to a species listed under the Federal ESA (desert tortoise). Desert Quartzite, LLC and the BLM expect to participate in formal consultations with USFWS pursuant to Section 7 of the ESA. A Biological Assessment (BA) will be submitted to USFWS, which will issue a Biological Opinion and Incidental Take Statement following completion of the consultation process. Desert Quartzite, LLC biologists conducted protocol biological surveys in the Project area in the fall of 2012 and the spring of 2013 and have provided the findings in a draft report to the BLM. The results of these studies will be considered in the EIS and be taken into account in designing the Project through the incorporation of measures to avoid, minimize, and, where necessary, mitigate impacts to the species.

Based on site conditions, the Project Site does not support nesting habitat for golden eagles, but is suitable for foraging by this species. Suitable nesting habitat may be present in the nearby mountainous areas south and west of the site. Desert Quartzite, LLC will coordinate with the BLM and USFWS to determine what effects on golden eagles are likely to result from Project-related losses of foraging habitat. If it is determined that the loss of foraging habitat would be likely to result in the "take" of golden eagles by precipitating decreases in eagle productivity, Desert Quartzite, LLC will obtain the required take permit from the USFWS.

Based on preliminary reconnaissance, most of the ephemeral drainages located on the Project Site are expected to be non-jurisdictional under Section 404 of the CWA because the drainages are neither navigable themselves nor hydrologically connected to navigable waters (see POD Section 6.1.3). If washes on the Project Site are connected with the Colorado River which is considered a navigable water they would be subject to Federal jurisdiction under Section 404 of the Clean Water Act. A formal delineation will be conducted to determine the federal jurisdiction (if any) of the washes on the Project Site. Consultation with the USACE will be required in order to obtain the agency's concurrence with the findings of the delineation and, if necessary, a Section 404 permit.

2.21.2 State Permits and Status

Table 2-7 provides a list of the State permits anticipated to be required for the Project, as well as the status of relevant permit applications. As currently proposed, the Project Site is located on BLM-administered lands. The proposed Project includes approximately 5 miles of upgrades (widening and graveling) to off-site roads to the east of the Project Site, including unincorporated Riverside County lands, in order to improve access. To the extent that the Project triggers State or County jurisdiction, compliance with the California Environmental Quality Act (CEQA) will be required. CEQA compliance would typically require a CEQA Initial Study and then preparation of a Negative Declaration, Mitigated Negative Declaration, or Environmental Impact Report.

Table 2-7 Status of Project State Permits and Authorizations

Permit	Lead Agency	Status
Endangered/Threatened Species Take Authorization under CESA and Sections 2050 (general provision for endangered species) and 2080 (take of endangered species) of the California Fish and Game Code	CDFW	The desert tortoise, listed as threatened under CESA, has potential to occur on-site and CESA review and approval is likely to be required. Focused biological surveys for sensitive species will be conducted for the Solar Facility Site (CDFW is expected to be a full participant in agency discussion between Desert Quartzite, LLC/BLM and the USFWS so that CDFW can complete a Consistency Determination with the project Biological Opinion issued by the USFWS. Informal meetings, e-mail discussions, and phone calls will be undertaken to streamline this process by familiarizing CDFW with the Project and eliciting agency concerns to be addressed throughout the process.
Section 1600-1602 Streambed Alteration Agreement process under the California Fish and Game Code	CDFW	Further assessment is needed to determine if drainage areas located on the Solar Facility Site are jurisdictional under the Fish and Game Code Sections 1600-1602. Desert Quartzite, LLC will work with CDFW to determine the applicability of Fish and Game Code Sections 1600-1602 and to prepare a Streambed Alteration Notification, if required.

Table 2-7 Status of Project State Permits and Authorizations

Permit	Lead Agency	Status
Construction and Operations Phase Storm Water Permits under California Water Code/CWA	California State Water Resources Control Board (SWRCB)	A SWPPP would be prepared as applicable to discharges to Waters of the U.S. The Applicant will design erosion control plans and implement SWPPP Best Management Practices under the direction of a Qualified SWPPP Practitioner (QSP) for storm water management and control. Preliminary BMPs are shown on Sheets 16 and 17 in Appendix C.
Section 401 Certification under CWA	Regional Water Quality Control Board (RWQCB)	CWA Section 401 certification would only be required in the event that a USACE Section 404 permit is required. If certification is required, Desert Quartzite, LLC will apply to the RWQCB to obtain certification.
Interconnection Agreement	CAISO	See Section 4.1.5 for the status of the Interconnection Agreement.
Fugitive Dust Control Plan	Mojave Desert Air Quality Management District	A fugitive dust control plan will be developed in accordance with Mojave Desert Air Quality Management District requirements prior to construction
Consultation on sacred areas to comply with State requirements.	Native American Heritage Commission (NAHC)	The NAHC will be contacted prior to beginning the NEPA analysis.

The Mojave Desert Air Quality Management District will be consulted before construction and during final Project design regarding fugitive dust emissions and the control of such emissions through adoption of a fugitive dust control plan.

Desert Quartzite, LLC specialists will conduct an assessment of potential waters within the Project Site subject to CDFW jurisdiction under the CGFC Section 1602. If the Project cannot avoid adversely affecting State jurisdictional drainages, a Streambed Alteration Agreement from CDFW would be required and applied for as needed. Desert Quartzite, LLC will consult with CDFW regarding any potential for State jurisdiction at the Project Site.

2.21.3 Local Permits and Status

Table 2-8 provides a list and status of the local permits anticipated to be required for the Project, as well as the status of these permit applications.

Table 2-8 Status of Project Local Permits and Authorizations

Permit	Lead Agency	Status
Land Use Review	Riverside County Airport Land Use Commission	Coordination and compatibility review to be conducted during environmental review process.

Construction Permits (e.g., Grading, Building, Electrical)	Riverside County and/or BLM	If such permits are required, they will be secured before construction activities commence.
Encroachment Permit	Riverside County, and/or BLM	Permit will be secured before construction activities commence, as necessary.

2.22 Financial and Technical Capability of the Applicant

First Solar (parent company of Desert Quartzite, LLC) is a recognized worldwide leader in solar PV manufacturing and development with a substantial track record. First Solar is a U.S.-based corporation with offices in Tempe, Arizona; Perrysburg, Ohio; San Francisco, California; and Bridgewater, New Jersey. First Solar also has 28 manufacturing lines worldwide, including locations in Perrysburg, Ohio, and Malaysia, with a total manufacturing capacity of 2.2 gigawatts (GW) in 2013. First Solar's current market capitalization is approximately $6.75 billion, and is one of the largest companies in the solar power industry.

The Project will utilize First Solar's proven thin film cadmium telluride (CdTe) PV technology, which is readily scalable to the Project's size. First Solar has developed and is continually refining manufacturing technologies that drive down the cost of its modules in order to offer reliable solar power at a price that is cost-competitive with other forms of non-renewable power generation. At the same time, the firm has continued to emphasize methods and programs for manufacturing and construction that are environmentally sustainable, such as its end-of-life management program for module collection and recycling. First Solar has installed over 8 gigawatts (GW) worldwide, and has multiple large-scaled project nearing construction completion, and/or in the early stages of operation, including the 550 MW Desert Sunlight Solar Farm Project in Riverside County, 550 MW Topaz Solar Farm in San Luis Obispo County, 230 MW AV Solar Ranch One Project in Los Angeles County, 400 MW Silver State Solar in Nevada, 300 MW Stateline Solar Farm in San Bernardino County, and 290 MW Agua Caliente Solar Project in Arizona.

3.0 Construction of Facilities

The construction of the Project will begin once all applicable approvals and permits have been obtained. It will take approximately 18 to 48 months from the commencement of the construction process to complete construction of the 300 MW Solar Facility and 230 kV Gen-Tie Line. The following sections provide detail about the Project timeline and process for the construction.

3.1 Solar Field Design, Layout, Installation, and Construction Processes

Appendix C, Site Plan Package, includes engineering design plans that depict the design and layout of the Project. The installation and construction processes for the Project are described in the following subsections.

3.2 Construction and Operations Approach

After the preconstruction surveys, construction mobilization, and site preparation are completed, construction of the Solar Facility and Gen-Tie Line will begin. Work will be completed in two, 150 MW blocks moving across the site so that completion of one block is closely followed by the beginning of the next.

3.3 Access and Transportation System, Component Delivery, Worker Access

A preliminary access road map is provided as SPP Sheet 18 (Appendix C). Proposed primary access to the Project Site will be provided from the I-10 freeway to SR 78 to S. Neighborhood Boulevard to 16th Avenue/Seeley Boulevard (see SPP Sheets 2 and 18 [Appendix C]). Secondary access (for limited large loads only) will be provided by I-10 to Mesa Drive to Orange Drive to 16th Avenue/Seeley Avenue, or I-10 to Mesa Drive to Orange Drive to 15th Avenue to Haig Drive to 16th Avenue/Seeley Avenue. The perimeter of the occupied portions of the Solar Facility will be fenced to limit public access. The entrance to the Facility will be gated and restricted to unauthorized entry. Permanent six-foot tall gated chain-link security fences with barbed wire will be constructed around the Solar Facility.

Desert Quartzite, LLC is considering shuttle buses as an option for transporting the construction workforce to the Project Site. A traffic study for the Project will be prepared as a part of the NEPA process.

3.4 Construction Workforce Numbers, Vehicles, Equipment, Timeframes

3.4.1 Construction Workforce Numbers

The typical construction work schedule is expected to be from 7:00 a.m. to 5:00 p.m., Monday through Friday. However, to meet schedule demands, it may be necessary to work early morning, evening, or nights and on weekends during certain construction phases. The work schedule may be modified throughout the year to account for changing weather conditions (e.g., starting the workday earlier in the summer months to avoid work during the hottest part of the day for health and safety reasons). In the event that construction work takes place outside these typical hours, activities will comply with Riverside County standards for construction noise levels. For safety reasons, certain construction tasks, including final electrical terminations, must be performed after dark when no energy is being produced. The Project will use restricted nighttime task lighting during construction. No more lighting will be used than is needed in order to provide a safe workplace, and lights will be focused downward, shielded, and directed toward the interior of the site to minimize light exposure to areas outside the construction area.

During Project construction, the workforce is expected to average approximately 600 employees over the 18- to 48-month construction period, with a peak workforce of approximately 1,000 employees. The Project

construction workforce will be recruited from within Riverside County and elsewhere in the surrounding region to the extent practicable.

3.4.2 Construction Equipment/Vehicles

Most construction equipment and vehicles will be brought to the Project Site at the beginning of the construction process during construction mobilization and will remain on-site throughout the duration of the construction activities for which they were needed. Generally, the equipment and vehicles will not be driven on public roads while in use for the Project. In addition to construction worker commuting vehicles, as discussed above, construction traffic will include periodic truck deliveries of materials and supplies, recyclables, trash and other truck shipments.

Truck access to the site will be from I-10 to Route 78 south via Exit 236, and then west on 16th Avenue/Seeley Avenue to the site access gate. Approximately 20,000 truck deliveries are expected over the Project construction period. Construction truck deliveries and shipments will typically avoid the peak traffic hours in the morning and evening, so it is unlikely that Project deliveries will represent a substantial increase in traffic volumes during peak commuting hours. Materials will typically be delivered starting two weeks before the start of the associated task with the exception of electrical gear (PCSs, PVCs, etc.), which will be drop shipped just prior installation.

3.4.3 Construction Timeframe

The construction of the Project will begin once all applicable approvals and permits have been obtained. Desert Quartzite, LLC plans to construct the Project beginning in late-2015 over an 18- to 48-month schedule depending on market conditions. Construction of the Gen-Tie Line would take place concurrently with the construction of the Solar Facility.

3.5 Preconstruction Surveying and Staking

Surveying includes two main objectives: 1) obtaining detailed topographic information for supporting the storm water modeling and grading design, and 2) construction layout surveying with staking. Desert Quartzite, LLC will complete detailed (one-foot interval accuracy) topographic information for the Solar Facility ROW using photogrammetry and field cross sections. Concurrent with the acquisition of topographic data, aerial photographs will be obtained and analyzed to determine changes in land use and stream channel configurations. The final Site Plans for the Project will be based on the detailed topographic survey of the site that is being performed as a part of the permitting and engineering design process.

Road corridors, buried electrical lines, PV array locations, and the locations of other facilities will be located and staked in order to guide construction activities. Preconstruction survey work will consist of staking and flagging the following: 1) ROW and construction area boundaries, 2) work areas (permanent and short term), 3) cut and fill, 4) access and roads, 5) transmission structure centers, 6) foundation structure, and 7) desert tortoise or endangered plant offsets. Staking and flagging will be maintained until final cleanup.

3.6 Preconstruction Site Preparation

Preconstruction activities will include installation of desert tortoise fencing and pre-construction surveys; installation of access roads and construction laydown and parking areas; and setting up offices and site services. A brief description of each of these activities is provided below.

3.6.1 Desert Tortoise Exclusion Fencing and Preconstruction Surveys

Prior to beginning pre-construction surveys, desert tortoise exclusion fencing will be constructed in specified areas. Pre-construction activities will include clearance surveys for desert tortoise and other sensitive species (e.g., Mojave fringe-toed lizard); relocation for desert tortoise; seasonal avoidance of nesting birds,

including burrowing owls; passive relocation of burrowing owls, as necessary; and possible transplantation of sensitive plant species including foxtail cactus.

Pre-construction survey work will also consist of staking and flagging the following: 1) ROW and construction area boundaries, 2) construction laydown, parking, and work areas, 3) final grade, 4) access and roads, and 5) foundation structures for facilities. Staking and flagging will be maintained until final cleanup.

3.6.2 Access Roads and Construction Laydown and Parking Areas

The proposed main access route to the Project Site will be from I-10 to Route 78 south via Exit 236, and then west on 16th Avenue/Seeley Avenue to the site entrance gate at the northern Project Site boundary. Additional Solar Facility access may be identified, as needed. Approximately five miles of the off-site access roads will need to widened and graveled. Graded, graveled, all-weather roads will also be required in selected locations within the Solar Facility during construction to bring equipment and materials from the staging areas to the construction work areas. These roads will be maintained for long-term Project operation and maintenance. The area of disturbance required for these roads is included in Table 2-3. The off-site access road route to the Project Site is depicted on SPP Sheet 18 (Appendix C).

Three temporary on-site construction staging areas, totaling approximately 83 acres, will be utilized throughout the Project construction period. The staging areas within the Solar Facility Site will include material laydown and storage areas and an equipment assembly area. The staging areas will be un-paved and un-graveled but will be treated with dust palliative and water periodically to control dust. The staging areas within the Solar Facility Site will be replaced with PV arrays once the areas are no longer needed for staging.

Construction materials in the laydown areas will be stored in uncovered rows grouped according to the type of material: steel piles, PV modules, table frames, tilt brackets, hardware, electrical cables etc. Electrical equipment such as transformers, PVCSs, and PCSs will be drop shipped shortly before installation to the locations where they will be installed, rather than stored in the laydown areas. Aggregate will be delivered at a rate proportional to spreading for access roads, building foundations, and other equipment foundations.

3.6.3 Construction Offices and Site Services

Desert Quartzite, LLC will construct the main construction site offices and services area in the northern portion of the Solar Facility Site. This area will be fenced with temporary construction fencing and will include temporary construction trailers, the safety office, field offices, recycling areas, and employee and visitor parking. Access to the construction area will be controlled by site security. A guard shack will be located near the entrance to the Project Site for site security.

3.7 Site Clearing, Grading, and Compaction

Construction grading and compaction techniques will be used to prepare the Project Site for safe and efficient installation and operation of the PV arrays. The discussion below provides preliminary detail relative to the site preparation techniques that may be employed at the Site; however, First Solar is conducting off-site tests of various site preparation and revegetation techniques. First Solar in conjunction with Desert Quartzite, LLC is currently exploring the use of agricultural methods for vegetation removal such as disking and compaction of vegetation, in order to minimize impacts from clearing and grading. First Solar will use the results of the off-site field testing to potentially adjust site preparation and construction methods, if appropriate, to minimize impacts to vegetation and facilitate site stabilization. However, at the time of the preparation of this POD, in order to be conservative in analyzing potential impacts from site preparation, it is assumed that the entire Solar Facility Site would be cleared and graded.

Site preparation techniques would be used to prepare the site for safe and efficient construction and operation of PV arrays while allowing water to sheet flow across the site with negligible impact on surface water flow upstream and downstream of the site. The planned approach to Project Site preparation, which involves the use of "disc and roll" and micrograding techniques, reflects the results of field testing of various site preparation techniques at an off-site location near the Project Site, as well as experience with construction of solar PV projects in other desert locations in Southern California and Nevada. First Solar has been using this experience to adjust and optimize its site preparation and construction methods. The disc and roll site preparation method does not involve removal of topsoil. Topsoil removed during limited grading activities at buildings (e.g., Operations and Maintenance facility) would be utilized for post-construction reclamation of disturbed areas or for balanced cut-and-fill needs at the site.

During Project decommissioning and reclamation, the Project Site soil and vegetation will be restored to its preconstruction condition with native vegetation similar to plants in the surrounding vicinity. Refer to Section 7.4 for additional details on Project decommissioning and reclamation.

3.7.1 Clearing

The Applicant prioritizes providing a safe working environment for construction personnel. In addition, construction vehicles would need to access the site for site preparation and array installation. For these reasons, the surface vegetation may need to be removed from the site. Vegetation would not be removed until the onset of a given construction phase. Within the solar field, facility roadways, and areas around the operations and maintenance building, vegetation would be disked under, mulched or composted, and retained on-site to assist in erosion control and limit waste disposal. In some areas to be graded outside of the solar field, native vegetation may be harvested for replanting to augment soil stabilization.

Vegetation would be cleared from roadways, access ways, and where concrete foundations are used for inverter equipment, substations, and the operations and maintenance building. Vegetation would be cleared for construction of the drainage controls. Organic matter would be mulched and redistributed within the construction area (except in trenches and under equipment foundations). Plant root systems would be left in place to provide soil stability except where grading and trenching are required for placement of solar module foundations, underground electric lines, inverter and transformer pads, road and access ways, and other facilities.

During the site clearing process, the site would also be cleared of refuse, as necessary. Refuse materials encountered would be recycled or disposed.

3.7.2 Grading

The cut and fill depths across the Site will be minimized, and it is expected that no import or export of soil material will be required, as the amount of cut and fill would be balanced on-site.

Areas that make up more than half of the solar field would be prepared using conventional farming equipment including tractors with disking equipment and vibratory rollers. This technique is referred to as "disc and roll" or Type 3 grading. With this approach, rubber-tired farming tractors towing disc harrow equipment would disc the top 5 to 7 inches of soil. A water truck would follow closely alongside the tractor to moisten the soil to hold fugitive dust emissions to acceptable levels. The tractor may make several passes to fully disc the vegetation into the topsoil, preserving the underground root structure, topsoil nutrients and seed base; once the soil has been wetted on the first pass, additional water would not be needed for subsequent passes. A drum roller would then be used to flatten the surface and return the soil to a compaction level similar to the preconstruction stage. The intent of the roller would be to level the soil under the solar field area and even out the surface after the disking is complete.

In dispersed sections of the solar array field, there would be limited use of scrapers to perform micrograding. This technique is referred to as "isolated cut/fill and roll" or Type 2 grading. In general,

portions of the site would be contour graded level; the macro-level topography and stormwater drainage would remain unchanged, but within each solar array, “high spots” would be graded and the soil cut from these limited areas used to fill “low spots” within the same array. Limited use of scrapers for micrograding would be employed only where needed to produce a more level surface than can be produced by the disc and roll technique.

Standard cut and fill techniques would be used in areas of the site where soil conditions do not lend themselves to disking. The overall objective of the earth moving would be to produce a consistent grade in each solar field area. Standard cut and fill techniques would be utilized within specific arrays to limit slope to within 3 percent. Essentially, the Solar Facility site would be graded to a sufficiently level topography using the least practicable amount of conventional cut and fill grading. The grading plan would utilize hydrology analysis to identify and protect areas that are susceptible to scour from stormwater runoff, and otherwise manage stormwater runoff to maintain plant facilities and safety and to ensure that off-site drainage conditions upstream and downstream of the site are as close as practicable to preexisting conditions. Work over the site preparation period would be paced so that grading of an area takes place shortly before trenching and post installation are ready to begin. This would minimize the area of open, uncovered ground present at any one time during construction, and thereby minimize dust and erosion issues.

Work over the grading period would be paced so that grading of an area takes place shortly before trenching and post installation are ready to begin. This would minimize the area of open, uncovered ground present at any one time during construction, and thereby minimize dust and erosion issues. Refer to SPP Sheet 15 (Appendix C) for the facility preliminary grading and compaction details.

3.7.3 Compaction

The Solar Facility construction process would require moving equipment across the site, including delivery trucks, pile driving equipment, and cranes. Soil would be compacted to a level that allows this equipment to move across the site. After grading and underground work, most areas would be compacted to approximately 85 percent. Dust palliative and water would also be applied to graded areas, as needed. Access roads would be treated with palliative and sprayed with water as needed during construction. Refer to SPP Sheet 15 (Appendix C) for the facility preliminary grading and compaction details.

3.8 Solar Array Assembly and Construction

The assembly, construction and installation phase involves assembly and installation of the PV solar modules and all the necessary electrical equipment to make the Project operational. After surveying and clearing, leveling, and compaction are conducted, construction and installation activities will include post installation; trenching and installation of underground cables; and installation of the Balance of System. Construction will also include installation of the Gen-Tie Line including tie-in to the CRSS. In general, the work tasks will follow in close sequence across the site, moving from south to north.

3.8.1 Trenching and Cable Installation

After the array areas have been surveyed, cleared and graded, trenches will be dug for the underground AC and DC cabling. Underground DC cables will connect rows of arrays with the PCS. Underground AC cables will connect the PCSs, transformers, and PVCSs. Trenches are dug for the underground AC and DC cabling, and the foundations for the inverter enclosures and transformers are prepared. Trenching will occur within each array to bury the AC and DC electrical cables. Trenching will also occur between the PCS and transformer locations. The trenched areas will be backfilled once the cables are buried and previous contours restored. During construction, desert tortoises and other wildlife may become entrapped within open trenches. This potential impact would be avoided, minimized or mitigated by implementing Desert Tortoise Exclusion Fencing and Translocation Plan. Additionally, the trenches would be excavated with slope inclines at 50-foot intervals, which would allow egress and prevent entrapment of wildlife.

Electrical cables are laid in the trenches and combiner boxes are also installed. Underground cables connect the PCSs to the on-site AC electric infrastructure, and also connect the PCS to the PVCS. Overhead lines connect the electrical output from the PVCS to the On-Site Substation. Refer to SPP Sheet 20 (Appendix C) for the facility preliminary electrical collection system details.

3.8.2 Support Post Installation

The next task to occur after trenching is complete in a work area is to drive the vertical support posts into the ground. These posts will hold the support structures, or tables, on which PV modules will be mounted. First Solar is evaluating various post installation equipment in the field, such as use of a small tracked-vehicle-mounted post driver to install the vertical support posts.

3.8.3 Balance of System (BOS) Installation

Approximately one week after posts are installed, crews will begin to install components comprising the balance of the system. These will include the PV modules and module framing assemblies. PV modules and module framing assemblies will arrive at the construction staging area in containers on tractor-trailers. The tractor trailers will utilize the gravel access roads to deliver the modules and the framing assemblies to the array areas. PV modules and the assemblies will be lifted from the tractor-trailers and placed adjacent to the array locations. Prefabricated tilt brackets attach the tables to the vertical support posts. Brackets also attach the PV modules to the tables and wire harnesses connect the PV modules to the electrical collection system. Vertical steel support posts are driven into the ground. The module framing assemblies, or tables, are then attached to the support posts using tilt brackets. Modules are manually carried from shipping containers to the location of installation. They will be placed on the tables and fastened with brackets at the top and bottom of the module.

The PCS enclosures are prefabricated structures mounted on prefabricated foundations or vaults. They will be installed at predetermined central locations within each block and then connected to incoming lines from the combiner boxes. After the blocks are installed in a particular area, traffic is expected to be limited to infrequent low-impact traffic in the aisle ways between PV blocks for inspection, maintenance, and repair purposes.

During the final system validation and commissioning process, the DAS and monitoring systems will be brought online, the equipment tested, and operational readiness verified. Once commissioning is complete, the Project will be brought online and connected to the grid. Section 4.0, Related Facilities and Systems, provides a detailed discussion of the existing and proposed electrical transmission system.

3.9 Gravel, Aggregate, and Concrete Needs and Sources

Prior to construction, approximately 1.1 miles of site on-site access roads would be stabilized with gravel, and approximately 108.8 miles of on-site access roads would be compacted native soil material. The stabilization materials will be obtained locally to the extent possible. Concrete will be used to create foundations and pads for the On-Site Substation equipment, the O&M facility, and other Solar Facility structures, fence footings, and transmission structures. While both pre-cast and poured-in-place concrete pads/foundations will be used, inverter enclosures and transformers are placed on poured or pre-cast concrete foundations/vaults.

For the gravel access roads at the Solar Facility Site, gravel needs are based on two assumptions for the thickness of aggregate required. The access road from the main entrance to the construction trailers and laydown areas of the site will be surfaced with aggregate. Aggregate may be processed on-site from native materials using the power screener or may be obtained from a local vendor. Concrete will likely be obtained from local sources, as much as practicable.

3.10 Solar Module and Electrical Construction Activities

The following section describes those activities associated with solar module electrical construction and construction activities associated with installation of the Gen-Tie Line.

3.10.1 Solar Module Electrical Construction Activities

Groups of glass PV modules are installed onto the tables as described in Sections 2.4 and 3.8, and are wired to the PCS using wiring harnesses with touch-safe connectors. Modules are manually carried from shipping containers to the location of install. They are placed on the tables and fastened with brackets at the top and bottom of the module.

Once all the modules are installed in a block, they can be electrically connected. The modules are built with standard touch-safe wiring connectors. Workers walk behind each row and plug the wires from each module into a wiring harness that collects all power from each table.

An electrician connects all wiring harness to a combiner box. Each combiner box links the connections from the PV modules. All combiner boxes are wired via underground DC cables to the PCS enclosure. An electrician connects these wires to the inverters and other electrical equipment inside the PCS enclosure. The inverter converts the DC power to three-phase AC power which is fed into a step-up transformer.

Transformers are connected via underground AC cables to the PVCS. Each PCS combines the power output from multiple arrays. Power is then transferred via overhead lines that route all power to the On-Site Substation. The On-Site Substation will step the power up for transmission via the Gen-Tie Line to the SCE CRSS.

Certified electricians in the construction workforce will perform appropriate Project electrical construction activities starting with combiner box connections. Utility journeymen may be required to perform or supervise the higher-voltage electrical construction activities for the On-Site Substation and Gen-Tie Line.

During the final system validation and commissioning process, the DAS and monitoring systems will be brought online, the equipment tested, and operational readiness verified. Once commissioning is complete, the Project will be brought online and connected to the grid.

3.10.2 Gen-Tie Line Construction Activities

The Gen-Tie Line structures would be constructed of either tubular steel monopoles or lattice structures. Construction of the Gen-Tie Line will cause temporary disturbance within a construction corridor estimated at a width of 160 feet. However, the long term disturbance associated with the Gen-Tie Line will be limited to the foundations of the transmission structures and the footprint of the access roads.

Pre-construction activities for the Gen-Tie Line will consist of surveying and marking the ROW and structure locations and mobilization of equipment and materials. A laydown yard (within the Project Site) will be prepared for storage of materials.

Access roads will be developed to access the Gen-Tie Line facilities. This will include the permanent roads to the new transmission structure locations and temporary roads for construction. Temporary work areas around the transmission structures will be necessary during construction to accommodate pole assembly and erection. Clearing and grading will also be needed for wire setup sites. Puller and tensioner sites will require a large relatively level area to safely accommodate all the equipment required on a wire stringing operation. These sites will be determined once the wire pulls have been planned. During the construction period, no disturbance is expected beyond the 600-foot-wide study corridor and permanent disturbance will be limited to areas within the 160-foot-wide Gen-Tie corridor.

During erection of the Gen-Tie Line, transmission structures will be picked up from the material storage yard, hauled to various structure sites or marshalling yards and unloaded. Structures will be assembled in sections on cribbing that will provide for the proper alignment of the steel members. Steel sections will be laid out with hydraulic cranes. The pole base and top sections will be assembled at each structure site. Insulators and hardware may be placed on the structure prior to erection.

Foundations will be constructed at each transmission structure location. Various foundation types are being considered, including drilled-shaft anchor-bolted foundations, drilled-shaft embedded foundations, and vibrated steel casings. A crane will be used for pole erection to set the pole base sections on foundations. The grounding crew will follow behind the erection crew, installing the grounding. The crew will test the ground resistance after installation.

For this Project, conventional wire stringing using tension stringing equipment has been assumed. After stringing, wires will be sagged in accordance with specified sagging data, corrections, and offsets. After sagging, the wires will be dead-ended on the dead-end structures and clipped-in on the tangent and angle structures. Final inspection, testing, will need to be coordinated with functional checkout and commissioning of the substation equipment at each end of the line.

3.11 Aviation Lighting (Power Towers, Transmission)

The nearest airport to the Project Site is the Blythe Airport, located approximately 2.5 miles northeast of the northernmost portion of the proposed Project Site. There is also a small, privately owned airstrip operated by a crop protecting service (Cyr Aviation) located in Blythe approximately 7.5 miles directly east of the proposed Project Site in Blythe, and another small privately owned airport (W.R. Byron) located approximately 8.3 miles northeast of the Project Site, also in Blythe.

The Solar Facility itself is a low-profile facility; the arrays are a maximum of approximately 13-feet tall above the ground surface. Project transmission structures will be less than 200 feet tall and will be located at least 2.5 miles from the Blythe Airport. If it is determined to be required, aviation lighting will be installed on Project structures in conformance with FAA requirements.

There is essentially no potential for light interference from the solar arrays to local aviation: the PV modules used in the installation are black and absorb over 90 percent of the light received; as a result, glare from reflected sunlight is not an issue. These type of PV modules have been installed at numerous airports, including Denver International Airport and Nellis Air Force Base, and studies have found that the reflection from PV array installations do not cause problems for airplanes in the vicinity of these solar facilities.

3.12 Site Stabilization, Protection, and Reclamation Practices

Before Project construction begins, Desert Quartzite, LLC will determine the appropriate site stabilization measures to be utilized on the Project. A Preliminary Geotechnical Investigation (based on literature review) is presented in Appendix D of this POD, and a detailed geotechnical study is planned to support detailed project design. The detailed geotechnical study will provide valuable input with respect to soil conditions and needed stabilization measures.

After Project construction is completed, relatively minimal operations and maintenance activities are required during operations. Access roads and aisle ways will need to be maintained, but the project areas covered by panels can support revegetation. Therefore, Desert Quartzite, LLC is exploring options to allow for revegetation of the Project Site post-construction.

Desert Quartzite, LLC will have a Project fire prevention plan in place during construction. This plan will comply with applicable Riverside County regulations and will be coordinated with the local Fire Department. During construction, the following steps will be taken to identify and control fires and similar emergencies:

- A network of access roads will be constructed for adequate fire control and emergency vehicle access to the site.
- Electrical equipment that is part of the Project will only be energized after the necessary inspection and approval, so there is minimal risk of any electrical fire during construction.
- Project staff will monitor fire risks during construction and operation to ensure that prompt measures are taken to mitigate identified risks. The Applicant's staff vehicles will be equipped with fire extinguishers.
- Transformers located on-site will be equipped with non-toxic, mineral-oil-based coolant that is non-flammable, biodegradable and contains no polychlorinated biphenyls or other toxic compounds.
- Non-native species will be managed per an Integrated Weed Management Plan prepared for the Project Site.

At the end of the Project's useful life, Desert Quartzite, LLC will decommission the facility and remove aboveground facilities including the PV arrays and supporting electrical and facility systems. Following facility decommissioning and removal, the area will be reclaimed according to applicable regulations in effect at the time of decommissioning. Please see Section 7.4 for a discussion of the Project facility decommissioning plans.

4.0 Related Facilities and Systems

4.1 Transmission System Interconnect

The Project is proposed to interconnect to the grid at the existing SCE CRSS.

4.1.1 Existing Transmission System

The primary transmission system of adequate capacity to accept the proposed Solar Facility output and which is located in the vicinity of the proposed Project, is SCE's 500-kV DVP2 line, which runs from the Harquahala Substation (in Arizona, near the Palo Verde nuclear power plant) to SCE's Devers Substation (in North Palm Springs, California) along the same pathway as the existing DPV1. In the area near the Project Site, the DPV transmission corridor runs from the northwest to the southeast adjacent to the southwestern portion of the Solar Facility ROW and then due east (see SPP Sheet 4, Appendix C).

4.1.2 Proposed Transmission System

The medium-voltage collection system lines transmitting power from each PV block will be buried underground from the PCS to the PVCS and will be connected on overhead lines from the PVCS to the On-Site Substation. At the On-Site Substation, the Project's output will be stepped up to the voltage required for interconnection. The Gen-Tie Line will connect the On-Site Substation to the CRSS, where it will be connected to the existing grid.. The Project's Gen-Tie Line would run north from the On-Site Substation, located in the northwest portion of the Solar Facility Site, to the proposed utility corridor running east-west along the 16th Avenue alignment, due west along the proposed utility corridor, and then south to the CRSS (see Figure 2–2 and SPP Sheet 3, Appendix C).

The transmission of the high voltage power produced by the Project would use overhead construction. Under this method of construction, the transmission conductor would be strung overhead on the supporting transmission structures. Heights of structures for the Project would vary depending on the electrical clearances required but would be less than 200 feet in all cases.

4.1.3 Ancillary Facilities and Substations

Other than the On-Site Substation, Gen-Tie Line, and CRSS, which have been described previously, there are no further ancillary transmission facilities necessary for the Project.

4.1.4 Status of Power Purchase Agreements

Desert Quartzite, LLC is pursuing the sale of power from the Project to utilities and other retail purchasers.

4.1.5 Status of Interconnection Agreements

The Project CAISO interconnection request was submitted on December 15, 2010 2 with a CAISO Interconnection queue date of March 31, 2011. Phase 1 and Phase II cluster studies have been completed The CAISO interconnection process is being reviewed by stakeholder groups for possible tariff modifications that may impact future process timelines.

4.1.6 General Design and Construction Standards

The specific engineering design for the above described facilities will be negotiated between Desert Quartzite, LLC, SCE, and CAISO once the Final Facilities Studies are complete. The Project will comply with Riverside County, State of California, and International Building Codes. Additionally, the Project will be designed in conformance with the National Electrical Code.

4.2 Gas Supply Systems

The Project will not utilize natural gas for power production.

4.3 Other Related Systems

4.3.1 Communications System Requirements

For transmission of operational data and to support employees working on-site, Desert Quartzite, LLC expects to utilize existing wired or wireless telecommunications facilities. In the event that these facilities are not available in the Project vicinity, Desert Quartzite, LLC would supplement with small aperture (less than one meter) satellite communications gear.

As described in Section 2.8.3, the solar facility would be installed with an estimated nine tracker anemometer towers around the site perimeter, which measure and communicate wind speed data to the facility control room for tracker positioning in the event of high winds.

In addition, the Solar Facility Site will be routinely patrolled by pickup trucks and all-terrain vehicles. These vehicles will be operated by supervisors and foremen and equipped with communications devices (cell phones and/or radios) to coordinate any emergency or fire-fighting issues internally and with the local fire department.

5.0 Operations and Maintenance

5.1 Operation and Facility Maintenance Needs

The Project is designed to have minimal moving parts, no thermal cycle, and no water use for electricity generation. This simple Project design will require only limited maintenance throughout its lifetime. Section 5.2 provides a discussion of anticipated maintenance activities.

5.2 Maintenance Activities

Project maintenance activities will generally include all-weather road maintenance; vegetation restoration and management; scheduled maintenance of inverters, transformers, and other electrical equipment; and occasional replacement of faulty modules or other site electrical equipment. The Project's all-weather access roads will be regularly inspected, and any degradation due to weather or wear and tear will be repaired. Dust palliatives will be applied on dirt access roads as necessary. This is expected to be needed only once every two to five years. Washing of solar panels is expected to occur up to twice per year.

5.3 Operations Workforce and Equipment

After the construction period, the workforce for operations and maintenance (O&M) and security purposes is estimated to be up to 15 full time workers. Typical work schedules are expected to be in two 12-hour shifts. During operations, potable water will be trucked into the site (one truck a week from Blythe) or on-site groundwater will be utilized, including treatment, as necessary. The O&M workforce will generate small amounts of sanitary wastewater that will be handled by an on-site septic system and leach field.

Only limited deliveries will be necessary for replacement PV modules and equipment during Project operation. Table 5-1 details the expected daily traffic to the Solar Facility Site during operations.

Table 5-1 Daily Vehicle Trips During Project Operation

Purpose	Operations Traffic
Employees (daily round trips)	up to 15
Deliveries (daily round trips)	up to 10

6.0 Environmental Considerations

The Project Site is located outside the boundaries of any Area of Critical Environmental Concern, Desert Wildlife Management Area, Wilderness Area, or designated Critical Habitat Unit.

Environmental considerations are summarized for the Project in Appendix A, Environmental Considerations Table. This table provides a list of the potential environmental impacts of the Project as well as environmental protection and mitigation measures that are proposed to avoid and reduce the Project's impacts. Particular environmental resources are also discussed in the following sections.

6.1 Special or Sensitive Species and Habitats

6.1.1 Habitat Description

A preliminary biological resources assessment was conducted for the Solar Facility Site in the fall of 2008 and the results of that assessment were provided previously to the BLM. Supplemental biological surveys and assessment were conducted in the fall of 2012 and the spring of 2013 and the results were provided to the BLM for review in 2014 in a draft report dated January 2014. Once the BLM's comments are received, the draft report (Biological Resources Technical Report, Desert Quartzite Solar Project, BLM Case File CACA-43937, Riverside County, California) prepared by Ironwood Consulting , Inc. will be revised and reissued. Key biological resource information from the January 2014 report is summarized herein.

Based on the biological surveys and assessments performed to date by Ironwood Consulting, Inc. for the Project, the Project Site area supports two primary vegetation communities: Sonoran Creosote Bush Scrub[13] (analogous to Creosote Bush-White Bursage Series[14]) and Desert Dry Wash Woodland[15] (analogous to Blue Palo Verde-Ironwood-Smoke Tree Series[16] [Sawyer and Keeler-Wolf 1995]) Sonoran Creosote Bush Scrub covers approximately 98% (7,160 acres) of the Project study area utilized for biological resources which encompasses a 1-mile-wide buffer around the outside of the proposed Project Site. Sonoran creosote bush scrub is dominated by creosote (*Larrea tridentata*) and white-bursage (*Ambrosia dumosa*). Within the Project Site Area, this vegetation community is characterized by sparse, relatively low-growing individual shrubs (see Figure 6-1).

Desert Dry Wash Woodland is located in three distinct wash systems within the expanded study area for biological resources (one originating from the McCoy Mountains in the northwest and the two originating from the Mule Mountains in the southwest), comprising approximately 2% (112 acres) of the expanded study area for biological resources. Desert Dry Wash Woodland is characterized by drought-deciduous, microphyllous trees, including palo verde (*Cercidium* sp.), and is associated with ephemeral watercourses (see Figure 6-2). Wildlife species richness is typically higher in Desert Dry Wash Woodland than other desert vegetation communities because it often contains increased shade, vegetation refuge for birds, available water, and wildlife migration opportunities on a local and regional scale. This community is considered a sensitive plant community by the BLM and the California Resources Agency. The three areas

within the expanded study area for biological resources that contain desert dry wash woodland may serve as movement corridors for large mammal species including mountain lion (*Felis concolor*) and burro deer (*Odocoileus hemionus eremicus*).

6.1.2 Special Status Species

The potential for occurrence of special status species on the Project Site was assessed through a search of the California Department of Fish and Wildlife's (CDFW) California Natural Diversity Database (CNDDB)

and the California Native Plant Society's (CNPS) Online Inventory of Rare and Endangered Plants, and intensive biological surveys of the Project Site in the fall of 2012 and the spring of 2013.

Special Status Plants

Six special status (California Native Plant Society list status) plant species were observed during the focused botanical surveys of the Project Site that were conducted in the fall of 2012 and the spring of 2013. The six plant species are: Harwood's milkvetch (Astragulus insularis var. harwoodii), Abram's spurge (Chamaesyce abramsiana), ribbed cryptantha (Cryptantha costata), Harwood's eriastrum (Eriastrum harwoodii), Utah vine milkweed (Funastrum utahense) and desert unicorn plant (Proboscidea althaeifolia). More than 124 species of plants were identified during the surveys. Table 5-1 presents a summary of the special status plant species found to be present on the Project Site, including their status. These plant species will be considered in the environmental review and threatened and endangered species consultation processes for the Project.

[1] Source: preliminary results of fall 2012 and spring 2013 field surveys performed by Ironwood Consulting, Inc. Final Biological Resources Technical Report is in progress.

No plant species that are federal- or state-listed as endangered or threatened have been recorded as occurring on or near the Project Site.

Special Status Animals

There is one federal-listed (threatened) and state-listed (threatened) animal species likely to inhabit the Project Site: the desert tortoise (*Gopherus agassizii*).

The USGS has developed a model for assessing the relative value of an area's potential as habitat for desert tortoise[17], and this model was used to assess the potential for desert tortoise habitat within the Project Site. The model is based on a comparison between known desert tortoise presence/absence data with ten environmental criteria that define or influence desert tortoise habitat, including soil characteristics, perennial and annual plant cover, elevation and topographic variables, and seasonality and variability of precipitation. The model provides output on the statistical probability of habitat potential, which can be used for mapping potential areas of desert tortoise habitat. Of note, however, the model does not account for anthropogenic changes that may have decreased habitat suitability in an area.

The results of the USGS habitat model ranking for the Project Site indicate that desert tortoise habitat potential varies across the Site from low to medium-low. The eastern portions of the Site have the lowest habitat potential score and the northwestern portions of the site have the highest (though still only moderate) habitat potential. In general, the model shows that the areas close to the Colorado River, including the Project Site, have lower potential for desert tortoise habitat than areas further to the east and west.

Full-coverage surveys for desert tortoise (Gopherus agassizii), the only animal species listed as federal and state endangered with potential to occur on-site, were conducted in 2013. Tortoise sign observed during the

[17] Nussear, K.E., T.C. Esque, R.D. Inman, L. Gass, K.A. Thomas, C.S.A. Wallace, J.B. Blainey, D.M. Miller, and R.H. Webb. 2009. Modeling Habitat of the Desert Tortoise (Gopherus agassizii) in the Mojave and Parts of the Sonoran Deserts of California, Nevada, Utah, and Arizona. U.S. Geological Survey Open-File Report 2009-1102.

surveys consisted of six carcasses, all-greater than 4 years old and disarticulated, and one set of tortoise tracks. Live desert tortoise were not observed during surveys.

Numerous Mojave fringed-toed lizards (Una scoparis), which is a species of concern, were found while performing surveys in the western portion of the Project Site, including the 230 kV Gen-Tie Line corridor, where soils consist of much finer sand.

Other special status wildlife species observed or likely to occur within the Project Site included loggerhead shrike (Lanius ludovicianus), burrowing owl (Athene cunicularia), LeConte's thrasher (Toxostoma lecontei), American badger (Taxidea taxus), desert kit fox (Vulpes macrotis arsipus), pallid bat (Antrozous pallidus), small-footed myotis (Myotis ciliolabrum), and Townsend's big-eared bat (Plecotus townsendii).

These special status animal species, as well as others such as golden eagles (Aquila chrysaetos) will be considered in the environmental review and threatened and endangered species consultation processes for the Project.

6.1.3 Jurisdictional Waters

The majority of washes on the Project Site drain towards the center of the site where they fan out and lack hydrological characteristics. Because these washes are not contiguous with a navigable or relatively permanent water (RPW), and thus would be considered "isolated waters", it is expected that they are not subject to the jurisdiction of the U.S. Army Corps of Engineers (USACE) under Clean Water Act (CWA) Section 404 or the Regional Water Quality Control Board (RWQCB) under CWA Section 401. Based on the preliminary assessment, the wash system located in the far southwestern extent of the study area appear to drain into the Palo Verde Valley and potentially connect with agricultural drainages. These agricultural drainages may be hydrologically connected with the Colorado River, which is considered a navigable water and subject to USACE and RWQCB jurisdiction. A formal delineation will be conducted to determine the federal jurisdiction (if any) of all washes on the Project Site.

Several washes on-site may fall under the jurisdiction of the CDFW under Section 1602 of the California Fish and Game Code, which regulates all changes to the natural flow, bed or bank, of any river, stream, or lake that supports fish or wildlife resources. Under Section 1602, a stream is defined broadly as a body of water that flows at least periodically, or intermittently, through a channel that has banks and that supports fish or other aquatic biota. Several washes with bed and bank and intermittent flow occur on-site. These systems also support Desert Dry Wash Woodland, which is considered a riparian community subject to CDFW jurisdiction. The largest wash system originates to the northwest of the Project Site at the base of the McCoy Mountains and flows diagonally across the northern sections of the site before exiting the eastern boundary and terminating at an existing agricultural field located adjacent to the site. Another prominent wash system flows northeast from the northeastern reaches of the Mule Mountains. This wash system extends to the DPV1 corridor then fans out onto the flat mesa within the Project Site. The final wash is located in the far southern portion of the site. This wash is a tributary to a larger drainage feature located off-site to the south, which flows into the Palo Verde Valley.

6.2 Special Land Use Designations

Several Areas of Critical Environmental Concern (ACEC) are located within the region. The Chuckwalla Valley Dune Thicket ACEC is located approximately eight miles to the west of the Project site. The Mule Mountains ACEC is near the southwestern border of Project Site. The Project design will provide a buffer between the ACEC and the Project Site. The Palen McCoy Wilderness Area is located approximately 12 miles to the northwest of the Project Site.

The entire Project Site, including Gen-Tie Line corridor are on BLM-administered land. This land is administered by the BLM pursuant to the CDCA Plan. The Project Site lies within the planning area designated under a 2002 amendment to the CDCA Plan, known as the Northern and Eastern Colorado Desert Coordinated Management Plan (NECO Plan). According to the NECO Plan, the Solar Facility Site and Gen-tie Line are located on land classified as Multiple Use Class M (Moderate Use), which are lands managed to provide for a wide variety of uses including mining, grazing, recreation, utilities and energy development, while conserving desert resources and mitigating damage to those resources caused by permitted uses. The CDCA management plan further designates utility-scale solar development as an allowable use within the Eastern Riverside SEZ.

6.2.1 Visual Resources

The Project Site is located within the Chuckwalla Valley within the Mojave Basin and Range physiographic province, which is typified by small, rocky mountain ranges with jagged peaks alternating with talus slopes and desert floor. Visually prominent mountain ranges near the Project Site include the Big Maria Mountains to the north, McCoy Mountains to the northwest, and Mule Mountains and Palo Verde Mountains to the south. Although the Eastern Riverside SEZ is generally natural appearing, cultural modifications within the SEZ detract somewhat from the SEZ's scenic quality. In addition to I-10 north of the Project Site, several dirt roads cross the SEZ, including through the Project Site. Additionally, the Project Site is bordered by the CDD Utility Corridor, which contains multiple high-voltage transmission lines. The BLM conducted a Visual Resource Inventory (VRI) in 2010, and designated the Project area SEZ as Class II, which is the highest rating for lands without special designation.

However, site-specific impact assessment would be needed to systematically and accurately assess visual impact levels for the proposed Project. Once appropriate visual impacts have been identified for the Project, implementation of the programmatic design features intended to reduce visual impacts from the Solar Energy Development in Six Southwestern States PEIS, Appendix A, would be expected to reduce visual impacts associated with utility-scale solar energy development.

A Visual Impact Assessment will be performed to support the EIS for the Project.

6.2.2 Rangeland Resources

No livestock grazing is authorized within the East Riverside SEZ, including the Project area. As a result, the Project would have no impacts on livestock grazing. The closest BLM Herd Management Area (HMA) is the Cibola-Trigo HMA, which is located in Arizona and is approximately 9 miles east of the Project Site. The closest wild horse and burrow territory is located within the San Bernardino National Forest, and is more than 70 miles northwest of the Project area. The Project would result in no impacts to wild horse and burrow HMAs and territories.

6.2.3 Military and Civilian Aviation

The Project Site does not appear to be located within a Military Operations Area (MOA), but may potentially be located within the path of Military Training Route(s) (MTRs), based on preliminary review of the Riverside County Airport Land Use Compatibility Plan (Riverside County Airport Land Use Commission [RCALUC] 2004). Therefore, consultation with the Department of Defense (DoD) would be expected prior to approval of Project activities that may adversely affect the use of the MTRs.

The Project Site is located approximately 2.5 miles southwest of Blythe Airport, which is a municipal public located on the north side of I-10. The Project Site is not located within the airport influence area, as defined by the outer edge of the Federal Aviation Regulations (FAR) Part 77 conical surface. Two northern portions of the Project Site are located within the airport Compatibility Zone E. According to the Riverside County Airport Land Use Compatibility Plan (RCALUC 2004), power plants are considered generally compatible in

Zone E, and airspace review would be required for objects over 100 feet tall, objects located on high ground, or solitary objects (i.e., antenna) more than 35 feet above the ground.

6.3 Cultural and Historic Resources

The following paragraphs provide a very brief overview of the cultural resources context for the Project. A Class I cultural resources records search and literature review has been completed and a Class III field survey of the Project Site will be performed in the future. No other site-specific cultural resources investigations have yet been conducted to date. The information presented below is based on the results of the records search and literature review, along with the personal experience of Project cultural resources consultants.

The Project Site is in an area known to be rich with cultural resources. Studies of other nearby planned energy projects (e.g., Blythe Solar Power Project and Genesis Solar Energy Project, north and northwest of the Project Site, respectively) have demonstrated that a wide variety of cultural resources from the prehistoric and historical periods are found in the region. The high density of cultural resources can be attributed to the proximity of the Colorado River and other natural resources. Prehistoric occupation of this area began several millennia ago and is largely found along the relic channel of the Colorado River and in the floodplains and bajadas of the north-south trending mountain ranges that border the Project area to the southwest and north.

Prehistoric materials are especially prevalent along the western edge of the relic channel of the Colorado River where people collected tool stone from the elevated cobble terraces that were created by flooding episodes of the Colorado River prior to its settling in its current location to the east. Areas along the bajada slopes of the small mountain ranges bordering the Project area to the west and north are deeply incised by seasonal drainages. These washes that are home to several species of trees and plants that would have provided food resources to prehistoric travelers moving through this portion of the desert. These same locations also often contain outcrops of minerals such as quartz that were valued as tool stone, and quarried by people in prehistory for this purpose.

Historically, the Project region was widely used for civilian mining and agricultural pursuits and also as a training area by General George Patton during World War II. Patton's Desert Training Center, California-Arizona Maneuver Area (DTC-CAMA), covered large portions of the desert in California, Arizona, and Nevada, and has left its mark on the landscape in this area. Throughout the region, remnant archaeological signatures from the DTC-CAMA are readily visible. Foxhole features, refuse dumps, camp areas, and other features related to various practice maneuvers are common. In addition to the DTC-CAMA, the area was subjected to military maneuvers for two weeks in 1964 during Operation Desert Strike. Because of the use of military surplus, the archaeological signature of Operation Desert Strike would be much the same as that from the DTC-CAMA with some technological variations (e.g., transition from C-rations to MCI rations). Failed attempts at agricultural and ranching pursuits dot the landscape in this region as well, and are identifiable archaeologically as the remnants of small homesteads. Along the mountainous areas, small mining sites are common and archaeologically evident through the presence of refuse deposits and long-abandoned mines or adits. There are also many "wildcat" refuse dumps related to the development of the town of Blythe dating as far back as the late 19th century.

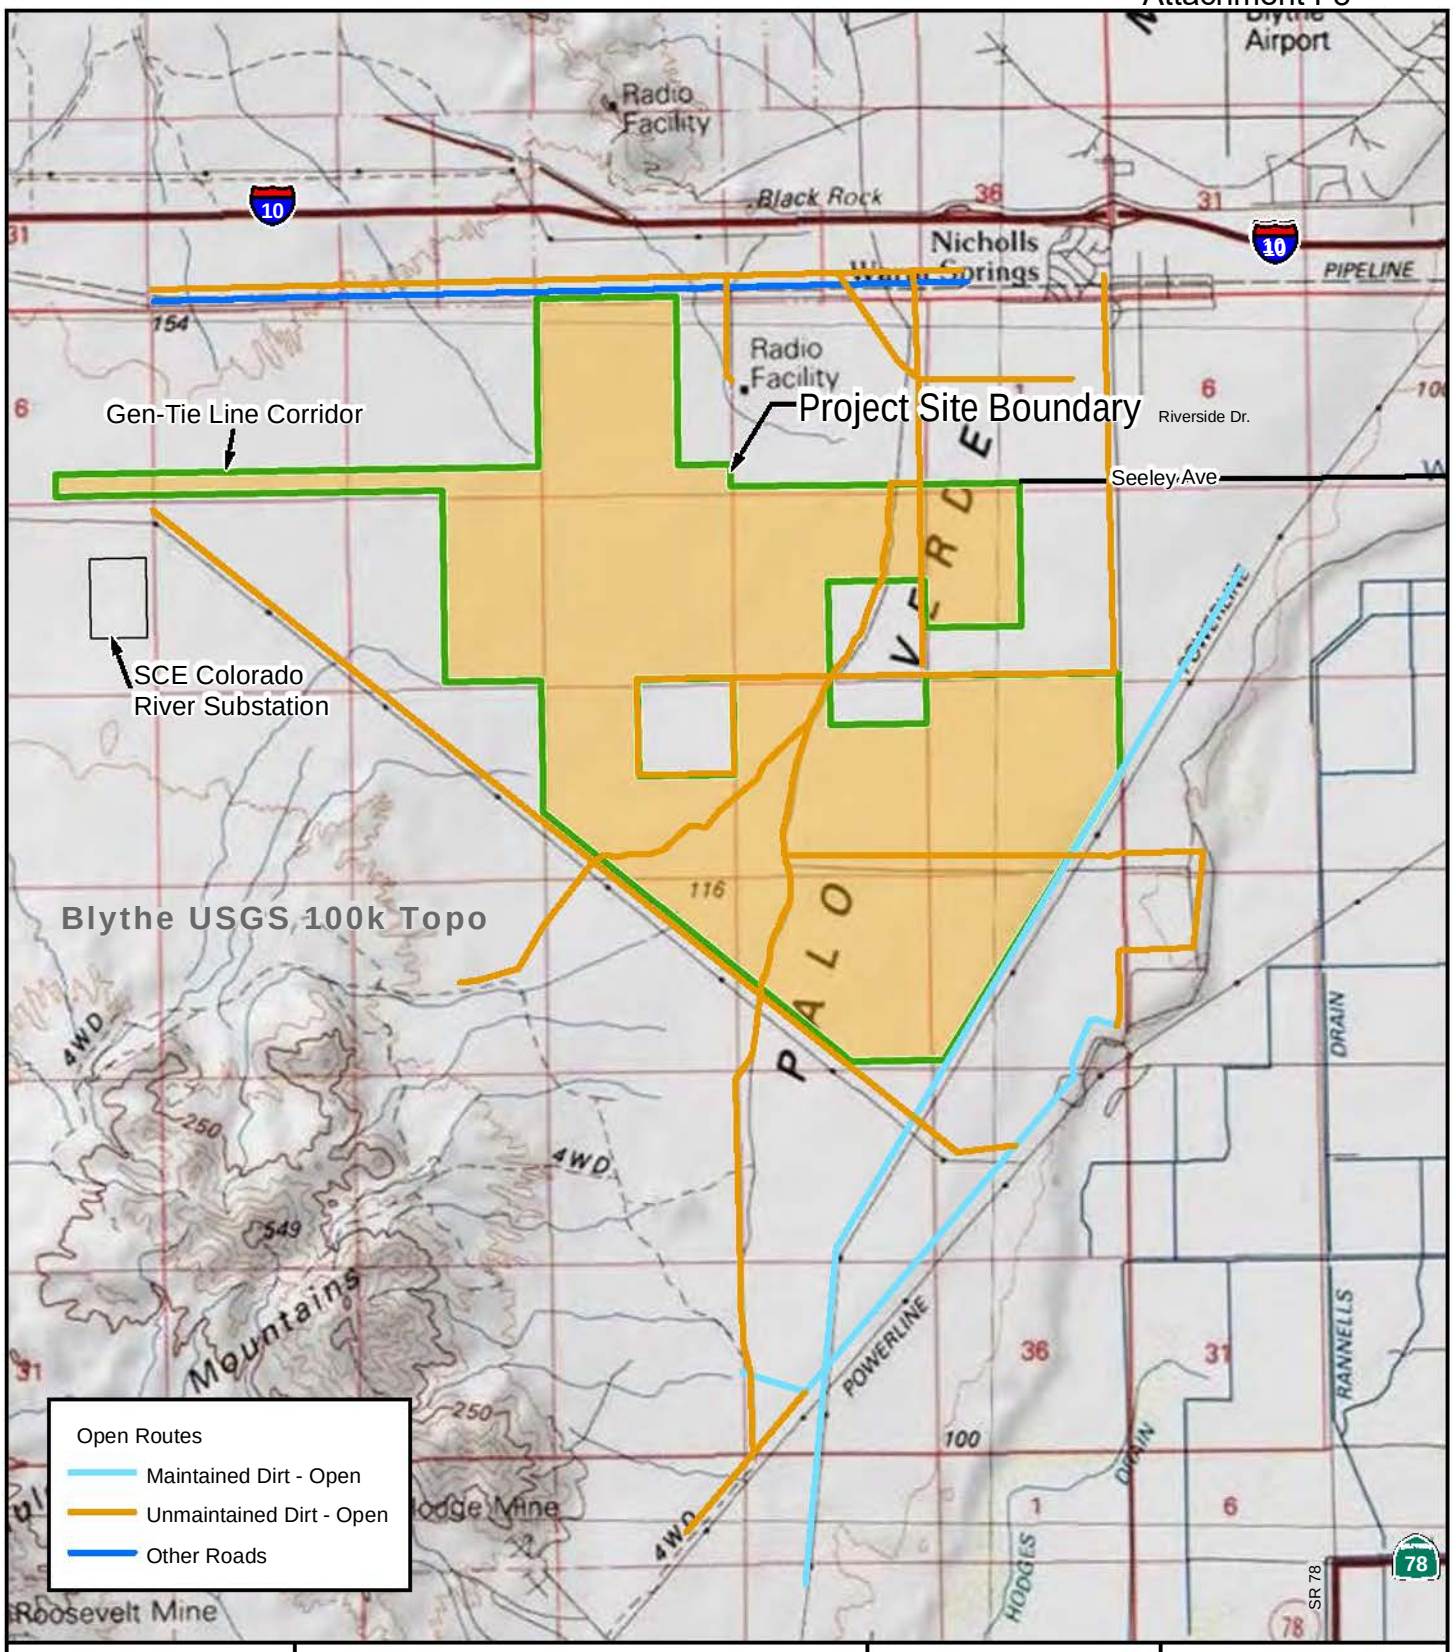
The location of the proposed Project is within areas that are likely to include a number of the resources discussed above. As noted above, and the records search has demonstrated that prehistoric and historical-period cultural resources are located in the Project area and the planned Class III cultural resources survey of the Project Site is expected to determine the presence and extent of these resources on-site.

6.4 Native American Tribal Concerns

A search of Sacred Lands File (SLF) from the Native American Heritage Commission (NAHC) in Sacramento was requested to determine if there are any known resources of traditional, religious, or historical importance to local Native American groups. Information letters were sent to all of the tribal contacts on a list provided by the NAHC, and responses have been received from several of them. The BLM will conduct government-to-government consultation with Native American tribes as part of the NEPA and National Historic Preservation Act compliance processes.

6.5 Recreation, and Off-Highway Vehicle (OHV) Resources

The Project Study Area is not designated by BLM as special recreation management areas and are managed for extensive recreation. Extensive recreation management areas typically experience light to moderate dispersed recreational use, including camping, hiking, hunting, and OHV and other vehicle travel along BLM-designated open routes. Several BLM roads that are considered Designated Open OHV Routes are located within the Project area, and are shown on Figure 6-3. Open BLM routes crossing areas granted ROWs for solar facilities would be redesignated as closed, and replacement of access lost for OHV use would be considered as part of the analysis of project-specific impacts, and recreational impacts would require consideration of developing alternative routes that would retain a similar level of access across and to public lands.



The primary routes crossing through the site include Blythe Way (which crosses the northern portion of the Solar Facility ROW) and several maintained dirt routes crossing the southern portion of the Solar Facility ROW. It is expected that these routes will remain open during and after construction of the Project, as will the routes accessing the private in-holding in the center of the ROW and the access roads along the transmission lines crossing the site. Construction of the Project may affect public access via some of the other unmaintained dirt roads that cross the area to be occupied by the Solar Facility. If this is the case, Desert Quartzite, LLC will work with the BLM and the OHV community to reroute existing routes where necessary to minimize impacts to public access. Rerouting of existing routes would comply with applicable regulations.

6.6 Groundwater Resources

The primary consideration for groundwater management within the Riverside East SEZ (including the PVMGB) relates to managing the allocations of water from the Colorado River, which is managed by an assemblage of compacts, federal laws, court decrees, and contracts that comprise the "Law of the River."[18] According to the "Law of the River" consumptive use of Colorado River water can occur through direct diversions of surface water, as well as through withdrawal of water from the river by underground pumping. To enable the United States Bureau of Reclamation (USBR) to properly account for the use of lower Colorado River water, and to ensure that existing and future use of the water is consistent with federal law, the United States Geological Survey (USGS), in cooperation with USBR, is developing a rule that establishes procedures for making determinations of unlawful use of lower Colorado River water. The proposed rule will:

- Adopt an " Accounting Surface" defined by groundwater levels that would occur if the Colorado River were the only source and sink for water in an aquifer that is hydraulically connected to the Colorado River floodplain;

[18] Ibid.

May 2014

AR060682

- Address under what circumstances an entitlement would be required for water pumped from underground wells near the Colorado River in order to identify groundwater wells outside the lower Colorado River floodplain that yield water that will be replaced by water from the Colorado River;
- Provide options for unlawful users to legitimize their lower Colorado River water use;
- Establish the criteria water users must satisfy to demonstrate that their wells do not pump water that would be replaced by lower Colorado River water;
- Establish a process for water users to appeal USBR determinations that specific wells pump Colorado River water; and
- Provide for public review and comment on the rule and methodology.

Currently, the "Accounting Surface," which is the static groundwater elevation in contributing basins that replenish the Colorado River, is used to determine if proposed pumping may fall under the "Law of the River." USGS defines static water-level as the level to which water will rise in a tightly cased well under its full pressure head when it is not being affected by groundwater withdrawal[19]. Wells that have a static water-level elevation above the "Accounting Surface" are presumed to yield water that will be replaced by water from precipitation and inflow from tributary valleys. Wells that have static water-levels equal to or below the "Accounting Surface" are presumed to yield water that will be replaced by water from the Colorado River, and therefore are subject to accounting and require an entitlement to use or divert river water. In general, if groundwater elevations go below the "Accounting Surface" elevation, then subsequent groundwater withdrawals are considered Colorado River extractions and may infringe on water rights established in the "Law of the River"[20] (Argonne, 2013).

The "Accounting Surface" extends to the margins of the Colorado River Aquifer which currently includes the PVMGB. The "Accounting Surface" elevation within the Project Site ranges from approximately 236 to 239 feet (National Geodetic Vertical Datum of [NGVD] 1929). Groundwater levels within the PVMGB are approximately 150 feet below ground surface and static water levels in groundwater wells in the vicinity of the site are at approximately 245 feet (NGVD 1929)[21]. Based on the Project's proposed groundwater use, it is anticipated that the Project groundwater pumping during operations would likely not result in drawdown that would affect the groundwater flow into the Colorado River, however this will need to be substantiated by further groundwater study and analysis to determine potential drawdown based on proposed withdrawal rates. The applicability of the "Accounting Surface" to the current Project has not currently been established.

A notice of the proposed "Accounting Surface" rule was published in the Federal Register on August 18, 2006, and the draft rule was published in the Federal Register on July 16, 2008. However, the Accounting Surface Method was withdrawn and has neither been acted upon, nor included as part of the Law of the River. The processes related to this action are continuing, but in general, coordination with USBR is required if it is anticipated that groundwater levels within the Project Site will be drawn down below the "Accounting Surface" groundwater elevation during groundwater pumping.

[19] Weile, S.M., Leake, .A. Owen-Joyce, S.J. and McGuire, E.H., 2009, Update of the accounting surface along the lower Colorado River: U.S. Geological Survey (USGS) Scientific Investigation Report 2008-5113, version 1.1, 16p. 3 plates in pocket.

6.7 Mitigation

In addition to the environmental protection measures identified in Appendix A, the Project will adopt the applicable desert tortoise protection measures prescribed by the NECO Plan and subsequent amendments, including the BLM 2012 Approved Resource Management Plan Amendments for Solar Energy Development in Six Southwestern States, and applicable measures adapted to the Project from the BMPs and mitigation measures prescribed by BLM, USWFS, and CDFW for renewable energy projects on public land.

As necessary, compensatory mitigation for loss of tortoise habitat may be part of the Project, at a ratio determined as part of the formal consultation with the USFWS under Section 7 of the Federal ESA and with CDFW under Section 2080 of CESA. In addition, mitigation may be provided for impacts to sensitive species as prescribed in NECO, and its appendices. Specific Project impacts to desert tortoise and its habitat, as well as mitigation for those impacts, will be addressed in during the EIS process and through the formal endangered species consultation process.

The Project will implement the general mitigation measures as set forth in the Desert Tortoise Mitigation Measures for the CDCA Plan of 1980 as amended by the NECO Plan and subsequent amendments, as applicable to the Project, as well as the Terms and Conditions of the Project BO and Incidental Take Permit.

Desert tortoise exclusion fencing will be installed around the Solar Facility Site prior to construction. Desert tortoise relocation will occur as described in the Project BO, Incidental Take Permit, and associated CDFW permitting, and will also be discussed in the Project Desert Tortoise Relocation Plan, which will be prepared and provided as an appendix to the Project EIS.

7.0 Supplemental Information

Desert Quartzite, LLC understands that supplemental information will be required from the Applicant in order to prepare the NEPA analysis and complete the review process, although it is not required to be submitted with the POD. Some of this information has already been developed and is readily available, and Desert Quartzite, LLC is summarizing this information below. Additional data will be developed and provided in the future, as more information is obtained during the Project design development phase.

7.1 Engineering and Civil Design

7.1.1 Facility Survey and Design Drawing Standards

The Project will comply with applicable survey, inspection, and design drawing codes and standards as designated by Riverside County, State of California, the Federal government, and International Building Codes. First Solar is a leader in the development of large-scale solar energy systems and, as such, has technical expertise in conducting facility surveys and preparing drawings and sketches using AutoCAD based on appropriate engineering specifications, design criteria and technical manuals. First Solar ensures conformance with applicable codes and standards as well as company policies and procedures and conforms to appropriate CAD, ANSI, and ISO drafting standards in both 2D and 3D formats.

7.1.2 Final Engineering and Civil Design Packages

First Solar has developed preliminary and conceptual engineering and civil design information, which are included in this POD as part of the SPP (Appendix C). The engineering and civil designs will be updated during development of the Project and will be finalized during EIS development prior to Project construction.

7.1.3 Watershed and Drainage Analysis and Calculations

A preliminary hydrological study of the proposed Solar Facility Site has been completed and is presented in Appendix E of this POD (TLA 2011). The study includes the results of a hydrologic analysis and hydraulic model of the Site for existing (i.e., pre-Project) conditions. The study includes the results of a watershed analysis that encompasses areas immediately upstream and downstream of the Site to determine and evaluate the Site's potential peak flows and off-site peak flows during 100-year storm event. The preliminary results of the hydrologic and hydraulic modeling of storm water flow rates and sediment transport rates will be considered in the final Project design.

The conclusions in the 2011 Drainage Report are presented below; refer to Appendix E for more information.

The proposed Project will cause minor impacts to the existing drainage shed area. The potential impacts will be minimized due to the relatively flat terrain and presence of large natural depressions that range from one to five feet deep. These large depressions store significant volumes of water which attenuate the increased runoff.

The post-Project impacts during the 100-year storm event are estimated as follows:

- Average Flow Depth increase of 0.03-feet
- Average Flow Velocity increase of 0.04 feet/second
- Total Outflow increase of 20 acre-feet (2.6%)

The nominal post-Project increases in flow depth, velocity and outflow can be mitigated with on-site retention basins sized with at least 20 acre-feet of combined storm water storage capacity.

The unmitigated post-Project sediment transport will be less than the pre-Project conditions due to soil compaction. The Project Site experiences relatively shallow and slow flows, so the nominal increases in post-Project flow depths and velocities do not overcome the decreased erosion potential due to compaction.

The maximum potential pier scouring at the solar array pedestal supports is 1.22 feet. The structural design and embedment depth of the solar panel pedestal piers should account for the maximum potential scour plus a factor of safety. Monitoring after large storm events should be implemented to detect piers with significant scouring.

7.1.4 Watershed Protection and Erosion Control Drawings

A map depicting the existing hydrological conditions in the vicinity of the Project is provided on SPP Sheet 11 (Appendix C). After the hydrologic assessment and design, described in Section 7.1.3, is complete, Desert Quartzite, LLC will provide a plan depicting post-construction hydrologic conditions. Desert Quartzite, LLC intends to design the Project, so that the post-construction storm run-off from the Project Site will be essentially the same as existing storm run-off conditions.

7.1.5 Final Site Grading Plans

Preliminary (30 percent) design grading and erosion control plans and details will be developed and provided to BLM based on the results of planned hydrologic modeling analyses described above. These Site Grading Plans will be finalized during EIS development and prior to Project construction.

7.2 Alternatives Considered by the Applicant

7.2.1 Alternative Site Evaluation Criteria

NEPA regulations (40 CFR § 1502.14 [c]) identify the need to consider reasonable alternatives. NEPA requires consideration of all aspects that may be relevant and important to decision-makers, including factors that are not related to environmental quality. NEPA requires substantial treatment of each alternative, including the proposed action, so that reviewers may evaluate their comparative merits (40 CFR Section 1502.14). The process of evaluating and selecting a suitable site for the Project involved application of a number of specific criteria.

Evaluation criteria included the following:

- High levels of solar insolation, as well as a contiguous area with reasonably flat topography that is large enough (several thousand acres minimum) for a 300 MW PV facility;
- Avoidance of areas that are highly pristine or biologically sensitive, such as an ACEC, DWMA, designated wilderness areas, National Park, etc. The site also should not be within a military facility or a park;
- Avoidance of high quality (Category I or II) desert tortoise habitat, or important habitat for other sensitive species or habitats (desert woodland wash habitat, dune habitat);
- Proximity to existing high voltage transmission facilities (230 kV or higher) with sufficient capacity for Project output and with suitable interconnection locations;

- Within a priority area for utility-scale solar energy ROWs (i.e., SEZs) identified by the Federal government[22];
- Good highway access and available for sale or lease/ROW at a reasonable cost; and
- Located in an area that has a history of development including transmission and road infrastructure and nearby industrial facilities.

7.2.2 Alternatives Considered but Not Carried Forward by Proponent

During the initial phases of Project planning, alternatives were identified that clearly did not meet the Project objectives, were technically disadvantageous, or had greater environmental impacts than the currently proposed Project. These alternatives were eliminated from further consideration. The alternatives that were considered, but not carried forward due to various constraints include those described below. These alternatives and possibly others will be analyzed in greater detail in the Project EIS.

Alternative Site Locations

Consideration was given to other areas along the I-10 corridor in reasonable proximity to the designated utility corridor that runs along I-10. However, much of the area is precluded from development by designation as ACEC, DWMA, wilderness, etc. Many potentially suitable areas outside these designated areas are precluded because they are in use or are proposed for energy projects (primarily solar). Private lands were considered as well as public lands. However, the potential for private land use is limited by the lack of large contiguous parcels of suitable size with a small number of owners (so that site control could be obtained relatively easily and at reasonable cost).

Alternative Transmission and Interconnection Locations

Southern California Edison (SCE) recently completed the CRSS at a site approximately 2 miles west of the Solar Facility Site; this substation was developed as part of SCE's upgrade of its transmission system to serve a number of renewable energy projects planned along the I-10 corridor in the Project vicinity. These planned projects include Solar Millennium's Blythe Solar Energy Project, NextEra's Genesis Solar Energy Project and Solar Reserve's Rice Solar Energy Project. Environmental documentation for the CRSS was developed as part of the environmental review process for these other projects (e.g., the environmental documentation for the Blythe Solar Energy Project includes environmental survey data for the CRSS site), although the CRSS has been developed and is owned by SCE.

The Project will interconnect with the SCE system at the SCE CRSS. Because of the proximity of the proposed Solar Facility Site to the CRSS site, the Applicant is not currently considering other interconnection locations. As shown on Figure 2–2 and SPP Sheet 3 (Appendix C), Desert Quartzite, LLC's plan is for the Project's Gen-Tie Line to run north from the On-Site Substation to the nearest point where it intersects with the planned utility corridor that crosses the Project Site in an east-west direction along the 16th Avenue alignment, which will contain the 230-kV interconnection transmission line extending from Solar Millennium's Blythe Solar Power Project north of I-10 to the CRSS. The Project Gen-Tie Line will follow the same path due west that is planned for the Solar Millennium line, and then south, until it reaches the CRSS, approximately 2 miles west of the Solar Facility Site boundary. The precise position of the proposed Gen-Tie Line relative to the planned Blythe Solar Power Project line has not yet been established; this will be worked out among Desert Quartzite, LLC, Solar Millennium, and SCE. Similarly the location where the Project Gen-Tie Line will enter the CRSS site and where within the CRSS facility the Gen-Tie Line interconnection

[22] BLM. 2012. Approved Resource Management Plan Amendments/ROD for Solar Energy Development in Six Southwestern States. October.

facilities will be located have not yet been determined but will be worked out between Desert Quartzite, LLC and SCE.

7.2.3 Comparative Analysis of Proponent's Alternatives

Through the Project impact analysis process, a number of alternative sites for the Solar Facility Site were evaluated, although as noted above because of the Project's proximity to the recently completed CRSS where the Project will interconnect with the SCE transmission system, alternative interconnection points or transmission routes are not being considered. A description and comparative analysis of the alternative Project configurations previously carried forward is provided in Section 7.2.4.

7.2.4 Alternative Site Configurations

Alternative sites for the main Project generation facilities and the Gen-Tie Line within the proposed Project Site area will be analyzed in greater detail by a BLM-selected consultant in the Draft EIS. SCE considered alternate sites for the CRSS. The preferred alternative for the Project Site includes the Solar Facility Site and Gen-Tie Line corridor as defined previously in this POD. Desert Quartzite, LLC is prepared to present further detailed data concerning Project alternatives during the NEPA process so that the EIS contractor can perform a sufficient level of analysis for the reasonable range of alternatives. Alternatives considered are described in the following paragraphs.

Solar Facility Site

As discussed throughout the POD, the original application to BLM for a ROW (approximately 7,236 acres) was larger than would be needed for the Project facilities themselves (the Solar Facility Site is now 4,660 acres). This was done to provide flexibility to configure the Project in a manner that is technically and operationally sound and also minimizes the potential for impacts on-site environmental and other resources. As discussed earlier, the Project Site area is traversed by a number of desert washes and includes topographic features (depressions) and other areas of environmental sensitivity. Also, the Mule Mountain ACEC is located near the southwestern border of the Project ROW. There were a variety of possible layouts for a 300 MW facility within the original 7,236-acre Solar Facility ROW area. The preferred Solar Facility Site is now focused on the more northerly portions of the ROW in order to provide a buffer between Project facilities and the Mule Mountain ACEC. The preliminary Site Plan for the Project also is laid out to minimize impacts on sensitive resources (e.g., desert washes). The NEPA process will further evaluate Project sites/configurations.

7.3 Facility Management Plans

7.3.1 Storm Water Pollution Prevention Plan (SWPPP)

A SWPPP would be prepared as applicable to discharges to Waters of the U.S. A formal delineation will be conducted to determine the federal jurisdiction (if any) of all washes on the Project Site. The Applicant will design erosion control plans and implement SWPPP Best Management Practices (BMPs) under the direction of a Qualified SWPPP Practitioner (QSP) for storm water management and control. Preliminary erosion control BMPs are shown on Sheets 16 and 17 in Appendix C. The BMPs to be implemented would manage storm water on the site to both protect the site and to minimize downstream erosion and sedimentation. Hazardous Materials Management Plan

Several methods will be used to properly manage and dispose of hazardous materials, petroleum products and hazardous wastes. Waste lubricating oil will be recovered and recycled by a waste oil recycling contractor. Chemicals will be stored in appropriate chemical storage facilities. Bulk chemicals are not expected to be used on-site. Most other chemicals will be stored in smaller returnable delivery containers. All chemical storage areas will be designed to contain leaks and spills in containment areas or containment

plans. A more detailed hazardous waste management plan indicating types, quantities, storage and management procedures, etc., will be prepared by Desert Quartzite, LLC for use in the Draft EIS.

7.3.2 Spill Prevention Control and Countermeasure (SPCC) Plan

If required, Desert Quartzite, LLC will prepare an SPCC Plan.

7.3.3 Waste Management Plan

All construction operational wastes produced at the Project Site will be properly collected, recycled (if possible), treated (if necessary), and disposed of in an appropriate manner and in full compliance with all regulatory requirements. Project wastes will include sanitary wastewater, non-hazardous waste, and potentially small quantities of hazardous waste, primarily liquid. Domestic waste streams such as showers and toilets will be treated using a septic tank and leach field. Heavy solids will settle to the bottom of the septic tank to undergo anaerobic decomposition and slight compaction, and will be removed, as necessary. Liquid effluent from the septic tanks will be distributed to a leach field. It is expected that the leach field will satisfy the needs of the Project for its entire service life. The leach field will be constructed of open tile drains laid in trenches filled with gravel or crushed stone. The trenches permit downward percolation or upward evaporation and transpiration.

Additional data on Project waste streams (quantities, types, storage, handling, and disposal procedures, etc.) will be prepared by Desert Quartzite, LLC for use in the Project EIS.

7.3.4 Integrated Weed Management Plan

Noxious weed control practices for the Project have been developed from existing Integrated Weed Management Plans contained in other PODs for Arizona, Nevada and California. Desert Quartzite, LLC will coordinate with the BLM, the CDFW and other jurisdictional agencies to identify target weed species for the Project. In addition, Desert Quartzite, LLC will coordinate with Caltrans to ensure that noxious weed controls for the Project area are in conformance with road management plans.

7.3.5 Health and Safety Plan

The Project will follow OSHA and CalOSHA requirements in its construction and operating activities. A safety and compliance director will be assigned to the Project to ensure that safety is given the highest priority. A site-specific Health and Safety Plan will be developed, identifying the roles and responsibilities of every employee with respect to safety on the Project.

7.3.6 Environmental Inspection and Compliance Monitoring Plan

Desert Quartzite, LLC will develop an Environmental Inspection and Compliance Monitoring program and plan for the Project, covering both construction and operation. A qualified individual will be designated to serve as the Project's Environmental Manager. The Environmental Manager will be responsible for development and implementation of the Project's compliance program. They will be responsible for communication and coordination with the applicable regulatory agencies and ensuring compliance with the various conditions and requirements of the full range of Project permits and approvals. The Environmental Manager will be responsible for the necessary record keeping and reporting required by Project permits. They will ensure that all applicable plans are up to date (e.g., Project SWPPP, Integrated Weed Management Plan). The Environmental Manager's role will include advising Project management of actual and potential compliance/non-compliance issues and for ensuring that Project planning takes appropriate account of compliance issues in advance.

A cultural resources monitoring and mitigation plan will be developed prior to construction that will identify areas to be monitored during construction by a qualified archaeologist. A discovery plan will be included in

the monitoring and mitigation plan that describes procedures to be followed in the event that subsurface archaeological materials are encountered during construction. The monitoring and mitigation plan will also include provisions for the education of construction workers about the importance of preserving significant cultural properties, and a process will be established for the workers to report and protect suspected discoveries. Curation of recovered archaeological materials will be arranged with an accredited curation facility.

Similarly, a monitoring and mitigation plan will be developed prior to construction that identifies areas to be monitored by a qualified paleontological professional. The plan will include measures to be followed in the event that fossil materials are encountered during construction. The plan will include worker awareness training to ensure that the construction personnel understand requirements and procedures to be followed in the event of suspected fossil discoveries. Curation of recovered fossils will be arranged with an appropriate curation facility.

7.4 Facility Decommissioning

The Project has a minimum expected lifetime of 30 years or more, with an opportunity for a lifetime of 50 years or more with equipment replacement and repowering. When the Project concludes operations, much of the wire, steel, and modules of which the system is comprised will be recycled to the extent feasible. The Project components will be deconstructed and recycled or disposed of safely, and the Solar Facility Site could be converted to other uses in accordance with applicable land use regulations in effect at the time of closure. Consistent with BLM and NEPA requirements, a detailed Decommissioning and Reclamation Plan (Decommissioning Plan) will be developed in a manner that both protects public health and safety and is environmentally acceptable.

7.4.1 Reclamation and Site Stabilization Planning

Conditions are likely to change over the course of a Project lifespan of 30 years or more, and a final Decommissioning Plan will be developed in the future prior to facility closure based on conditions as they occur at that time. The reclamation measures provided in the Decommissioning Plan will be developed to ensure protection of the environment and public health and safety and to comply with applicable laws, ordinances, regulations, and standards.

In general, the Project Decommissioning Plan will address:

- Proposed decommissioning and reclamation measures for the Project and associated facilities;
- Activities necessary for site restoration/re-vegetation, if removal of equipment and facilities is needed;
- Procedures for reuse, recycling, or disposal of facility components; collection and disposal of hazardous wastes; and use or disposal of unused chemicals;
- Costs associated with the planned decommissioning activities and the source of funding for these activities; and
- Conformance with applicable laws, ordinances, regulations, and standards.

The Decommissioning Plan will be developed in coordination with the BLM and submitted to the BLM for review and approval prior to final closure of the facility.

7.4.2 Temporary Reclamation of Disturbed Areas

After closure, measures will be taken to stabilize disturbed areas once equipment and structures are decommissioned and removed from the Project site. These measures will be outlined fully in the Decommissioning Plan. If and when Project structures are removed upon facility closure, the resulting

disturbed soil will be stabilized using standard erosion control BMPs (e.g., use of mulch, fiber rolls, silt fences, reseeding, etc., as applicable) until final reclamation measures may be implemented. Only a small portion of the Solar Facility Site contains structures that are in direct contact with the ground and thus would create surface disturbance during removal; these include access roads, the O&M facility, septic system and leach field, and associated parking areas; removal of the solar arrays will create minimal ground disturbance due to the small footprint of their pile foundation design. Final reclamation measures will be implemented as soon as practicable after facility closure. Desert Quartzite, LLC understands that some measures that support permanent reclamation may need to be taken prior to construction. For example, the reclamation plan may need to include stockpiling and maintaining a nursery for desert cacti, so that an ample supply is available for reclamation during facility decommissioning.

7.4.3 Removal of Power Generation and Substation Facilities

While there are no power generation facilities involved in the Project other than the PV modules, there will be several PCSs, PV Combing Switchgear cabinets, a Gen-Tie Line, and an On-Site Substation. As required, these facilities will be de-energized, decommissioned, dismantled, and removed in accordance with all Federal, State, and local regulatory requirements. Where feasible, Project components will be recycled or reused.

7.4.4 Removal and Recycling of PV Modules

As described in Section 2.14, First Solar is committed to philosophy of extended producer responsibility and improving the global environment, and as such has established a Collection and Recycling Program to offer its customers that promotes the collection and recycling of PV modules. The program enables substantially all components of the modules, including the glass and the encapsulated semiconductor material, to be treated and processed into new modules or other products. Under the program, First Solar funds, at the time of module sale, the estimated costs of collection and recycling including, packaging, transportation, and recycling costs for their PV modules.

7.4.5 Removal of Other Ancillary Facilities

The Project's ancillary facilities will include the O&M facility, parking areas, septic system and leach field, water storage tank, access roads, fencing, lighting, and related infrastructure. When the Project site is removed from power generation service, the Project's ancillary facilities will be reused, recycled, removed, or abandoned based on the desired subsequent use and in compliance with applicable Federal, State, and local regulations. Procedures for reuse, recycling, removal, or abandonment will be fully outlined in the final Decommissioning Plan. Where feasible, Project components will be reused or recycled. If the site is not planned for industrial, commercial, or residential development after Project decommissioning, ancillary facilities will be removed and the site will be restored to a condition that allows it to be utilized for natural habitat and as rural open space.

Appendix A Environmental Considerations Table

APPENDIX A
ENVIRONMENTAL CONSIDERATIONS
Desert Quartzite Solar Project

Resources	Project Effects on the Resource	Environmental Protection Measures
Special or sensitive species and habitats		
Listed Species - Desert Tortoise (*Gopherus agassizii*)	There is one federal- and state-listed (threatened) animal species with known potential to inhabit the Project Site: the desert tortoise. Full-coverage surveys for desert tortoise (Gopherus agassizii), the only animal species listed as federal and state endangered with potential to occur on the Project Site, was conducted in 2013. Tortoise sign observed during the surveys consisted of six carcasses, all-greater than 4 years old and disarticulated, and one set of tortoise tracks. Live desert tortoise were not observed during surveys. The USGS habitat model ranking indicate that desert tortoise habitat potential within the Project Site ranks as low to low-medium and is relatively lower than areas further to the west and across the Colorado River to the east. The Solar Facility Site will be developed and fenced with desert tortoise exclusion fencing and therefore will no longer be available as habitat to desert tortoise. Development of the Gen-Tie Line will also impact small areas of potential desert tortoise habitat (permanent transmission impacts will be limited to the footprint of the transmission towers and the access road).	The Project will adopt and implement the general mitigation measures as set forth in the *Desert Tortoise Mitigation Measures* for the CDCA Plan as amended by the NECO Plan and subsequent amendments, as applicable to the Project. A desert tortoise mitigation plan and, if necessary, a translocation plan will be developed in consultation with the USFWS and CDFW. Mitigation ratios and strategies adopted will be proportional to and consistent with the quality of habitat, which is very low, and with the identified and projected tortoise densities on the site. If it is determined that there are desert tortoises inhabiting the Project Site, clearance surveys will be conducted prior to Project construction. All tortoises found above-ground during clearance surveys would be fitted with transmitters and moved to a relocation area to be chosen in consultation with USFWS and CDFW. The Solar Facility Site would be fenced with desert tortoise exclusion fencing.
Candidate Species	There are no Candidate species known to occur in the Project area. Mountain plover and western yellow-billed cuckoo records were identified through a CNDDB search but habitat for these species was not detected within the Project area and these candidate species are therefore considered absent from the Project Site.	No environmental protection measures are expected to be necessary. If candidate species are discovered on-site during focused surveys, coordination and conference between the Desert Quartzite, LLC/BLM team and USFWS and CDFW will determine any necessary minimization and/or mitigation measures for these species.

APPENDIX A
ENVIRONMENTAL CONSIDERATIONS
Desert Quartzite Solar Project

Resources	Project Effects on the Resource	Environmental Protection Measures
Other Special Status Species--Wildlife	Numerous Mojave fringed-toed lizards (Una scoparis), which is a species of concern, were found while performing the fall 2012 and spring 2013 surveys in the western portion of the Project Site, including the 230 kV Gen-Tie Line corridor, where soils consist of much finer sand. Other special status wildlife species observed or likely to occur within the Project Site included loggerhead shrike (Lanius ludovicianus), burrowing owl (Athene cunicularia), LeConte's thrasher (Toxostoma lecontei), American badger (Taxidea taxus), desert kit fox (Vulpes macrotis arsipus), pallid bat (Antrozous pallidus), small-footed myotis (Myotis ciliolabrum), and Townsend's big-eared bat (Plecotus townsendii). These special status animal species, as well as others such as golden eagles (Aquila chrysaetos) will be considered in the environmental review and threatened and endangered species consultation processes for the Project.	Focused surveys for special status wildlife species have been conducted and will be considered as part of the environmental review and threatened and endangered species consultation processes in the EIS for the Project. Desert Quartzite, LLC is designing the Project facilities to provide the minimum level of disturbance necessary in order to complete the proposed Project. Desert Quartzite, LLC will work with the BLM to develop environmental protection measures to minimize impacts to sensitive wildlife species.

APPENDIX A
ENVIRONMENTAL CONSIDERATIONS
Desert Quartzite Solar Project

Resources	Project Effects on the Resource	Environmental Protection Measures
Other Special Status Species--Plants	Six special status (California Native Plant Society list status) plant species were observed during the focused botanical surveys of the Project Site that were conducted in the fall of 2012 and the spring of 2013. The six plant species are: Harwood's milkvetch (Astragulus insularis var. harwoodii), Abram's spurge (Chamaesyce abramsiana), ribbed cryptantha (Cryptantha costata), Harwood's eriastrum (Eriastrum harwoodii), Utah vine milkweed (Funastrum utahense) and desert unicorn plant (Proboscidea althaeifolia). More than 124 species of plants were identified during the surveys. These plant species will be considered in the environmental review and threatened and endangered species consultation processes for the Project. No plant species that are federal- or state-listed as endangered or threatened have been recorded as occurring on or near the Project Site.	Focused surveys for special status plant species have been conducted and the results of the surveys will be considered as part of the environmental review and threatened and endangered species consultation processes for the Project. Desert Quartzite, LLC will design the Project facilities to provide, to the extent practicable, the maximum avoidance of disturbance to special status plant species. Facilities (including transmission structures) will be designed to avoid and minimize impacts to these species. Desert Quartzite, LLC will work with the BLM to develop environmental protection measures to minimize impacts to sensitive plant species within the EIS.
Federal and State Jurisdictional Waters	The majority of the washes on the Project Site do not appear drain to a navigable or relatively permanent water, and thus would be considered “isolated waters” and would not be subject to the jurisdiction of the USACE under CWA Section 404 or the RWQCB under CWA Section 401. At least one wash system may be contiguous with agricultural channels and thus contiguous with the Colorado River, which is considered a navigable water and subject to USACE and RWQCB jurisdiction. Some of the washes on-site may fall under the jurisdiction of the CDFW under Section 1602 of the California Fish and Game Code under Section 1602. Several ephemeral washes with bed and bank occur on site that may be subject to State jurisdiction and may require a Streambed Alteration Agreement.	A formal delineation will be conducted to determine the federal jurisdiction (if any) of the washes on the Project Site. To the extent practicable, siting of the Project facilities will avoid jurisdictional waters. Attempts will be made to fully avoid likely jurisdictional drainages, however, if necessary, the Project will apply for a Section 404 permit and/or Streambed Alteration Agreement. If necessary, mitigation measures for impacts to jurisdictional waters would be determined in consultation with USACE related to Section 404 of the CWA and CDFW under Section 1602 of the Fish and Game Code.

APPENDIX A
ENVIRONMENTAL CONSIDERATIONS
Desert Quartzite Solar Project

Resources	Project Effects on the Resource	Environmental Protection Measures
Desert Dry Wash Woodland	Desert Dry Wash Woodland vegetation is associated with three desert wash systems located within the Project Site area.	To the extent practicable, siting of the Project facilities will avoid jurisdictional waters. If necessary, mitigation measures for impacts to desert dry wash woodland would be determined in consultation with BLM and CDFW and in keeping with requirements of the NECO Plan.
Desert Scrub Vegetation	Desert scrub vegetation occurs over approximately 98% of the Project Site area. Existing vegetation will be cut within all occupied portions of the Project area over the active life of the Project.	Cutting or removal of desert scrub wildlife habitat will be restricted to the occupied and fenced portions of the Project area. Desert Quartzite, LLC is evaluating via test site construction methods the minimum level of disturbance necessary in order to complete the proposed Project.
Wild or Scenic rivers	There are no wild or scenic rivers in or near the Project area, and none will be directly or indirectly affected by the Project.	Not Applicable
Introduction of Invasive, Nonnative Species	Soil disturbance and construction and operational activities could introduce invasive nonnative species to the Project area.	Applicant will develop an Integrated Weed Management Plan and provided in support of the Project EIS. The Plan will be implemented during all Project phases.
Migratory birds	The burrowing owl (*Athene cunicularia*) is protected by the federal Migratory Bird Treaty Act. Other native bird species, also protected by the federal Migratory Bird Treaty Act, may occur on the Project Site and could be affected by Project activities.	Nesting bird locations will be temporarily avoided during construction. To the extent practicable, burrowing owls will be avoided by siting of Project components. Mitigation for unavoidable impacts to burrowing owls will be mitigated in consultation with CDFW and will comply with the latest CDFW and California Burrowing Owl Consortium guidelines.
Special Land Use Designations		
Areas of Critical Environmental Concern (ACEC)	Mule Mountain ACEC is located approximately one mile southwest of the Project Area. The Chuckwalla Valley Dune Thicket ACEC is located 8 miles directly west of the Project. There will be no direct impacts from the Project on these ACECs.	The Solar Facility has been sited in the northern portion of the originally applied for ROW in order to establish a reasonable buffer zone between the Project and Mule Mountain ACEC.
Desert Wildlife Management Areas	The Chuckwalla DWMA for desert tortoise is located approximately 20 miles west of the site. No effects on the Chuckwalla DWMA are expected from the Project.	Not Applicable

APPENDIX A
ENVIRONMENTAL CONSIDERATIONS
Desert Quartzite Solar Project

Resources	Project Effects on the Resource	Environmental Protection Measures
Critical Habitat	No critical habitat will be directly or indirectly affected by the Project.	Not Applicable
Prime or Unique Farmlands	No prime or unique farmlands will be directly or indirectly affected by the Project.	Not Applicable
Wilderness Areas	There are no wildernesses or wilderness study areas in the Project area. The nearest Wilderness Areas are the Big Maria Mountains Wilderness 12 miles to the northeast, and the Palen McCoy Wilderness located about 10 miles to the northwest, both of which are north of Interstate 10.	None
Cultural and Historic Resource Sites and Values		
Cultural and Historic Resources	Historic cultural resources may occur within the Project area.	A Class I cultural resources records search and literature review has been completed and a Class III field survey of the Project area will be completed prior to completion of the Project EIS in conformance with BLM requirements. To the extent practical, Project facilities will be constructed in a manner that avoid potentially eligible cultural resource sites. Other measures will be implemented to mitigate potential adverse effect on identified cultural resources that cannot be avoided in conformance with BLM and State Historic Preservation Office (SHPO) requirements.
Native American Tribal Concerns		
Native American Tribal Concerns	No specific Native American concerns have been identified to date.	Desert Quartzite, LLC's consultant has requested a search of Sacred Lands File from the NAHC in Sacramento to determine if there are any known resources of traditional, religious, or historical importance to local Native American groups. The BLM will conduct government-to-government consultation with Native American tribes as part of the NEPA and National Historic Preservation Act compliance processes.

APPENDIX A
ENVIRONMENTAL CONSIDERATIONS
Desert Quartzite Solar Project

Resources	Project Effects on the Resource	Environmental Protection Measures
Paleontological Resources		
Paleontological Resources	No specific Paleontological Resource concerns have been identified to date.	A paleontological resource survey of the Project area will be conducted prior to site construction or surface disturbance in conformance with BLM requirements.
Recreation and OHV Conflicts		
OHV Recreation	There are no developed OHV recreation facilities in or near the Project area, but several BLM-designated open routes cross the Project Site. OHV use within the developed portions of the Project area will not be permitted for safety reasons.	Only developed and occupied portions of the Project area will be fenced. Designated open routes will either be re-routed or remain open to public access to the extent practicable. Desert Quartzite, LLC will work with the BLM and the OHV community to re-route any routes that are affected by the Project.
Other Recreation	There are no developed recreation facilities in or near the Project Study Area.	Desert Quartzite, LLC is designing the Project facilities to provide the minimum level of disturbance necessary in order to complete the proposed Project. Only developed portions of the Project Site will be fenced, thus minimizing limitations to existing recreational uses in the Project vicinity.
Other Environmental Considerations		
Air Quality		
Fugitive Dust Emissions	Approximately 4,682 acres[RR1] will be disturbed during Solar Facility site preparation. Small amounts of grading will also be required for construction of the Gen-Tie Line (limited to access roads, the footprints of the transmission structures, and some temporary work areas; acreage to be determined), and associated with upgrading of approximately 5 miles of off-site access roads.. Limited vehicle access will occur on unpaved roads and access corridors over the operational life of the Project.	A Fugitive Dust Suppression Plan will be developed and implemented, in conformance with Mojave Desert Air Quality Management District requirements, that will detail control measures to reduce fugitive emissions from construction and operational activities, including but not limited to watering of unpaved roads and other disturbed surface areas, vehicle speed limits, transport container covers, and cleaning and maintenance procedures.
Vehicle Emissions	An estimated 20,000 truckloads of solar modules and other construction materials will be delivered to the Project Site area during the construction period for the Project.	The potential impact from construction vehicle emissions will be evaluated during the NEPA process.

APPENDIX A
ENVIRONMENTAL CONSIDERATIONS
Desert Quartzite Solar Project

Resources	Project Effects on the Resource	Environmental Protection Measures
Hydrology and Water Quality		
Floodplains	FEMA has not mapped floodplains in the Project area. Periodic rain events in the Project vicinity could result in sediment-laden runoff onto or from floodplains in the Project area, especially during Project construction activities.	Any major floodplains demarcated by scouring or other hydrologic criteria in the Project area would be avoided during Project siting.
Desert Washes and other Surface Water	The Project site is located in a desert environment. Several desert washes exist within the Project site boundary. Although some surface water collects within the Project area, Desert Quartzite, LLC is exploring site preparation methods that will contain water draining onto the site, and fill the primary low areas if necessary, to avoid flooding hazard in limited portions of the site area. The Project area also contains washes that periodically contain water during infrequent events. An agricultural ditch surrounding an offsite jojoba farm also periodically contains water.	The Project will avoid the major desert washes and the agricultural ditch near the jojoba farm in its placement of PV arrays and other structures, to the extent practicable. If the Project cannot avoid adversely affecting these drainages, then a Streambed Alteration Agreement from CDFW will be obtained. Best Management Practices (BMP) will be developed and implemented for construction, post-construction, and operational phases to maintain the integrity of the desert washes in the area.
Storm water	The Project area is located in a large alluvial fan area with several washes that periodically collect runoff water during infrequent rain events. Site preparation studies will also evaluate the option of creating more of a sheet flow regime in lieu of the numerous washes which now drain the site. To the extent that washes are left intact, it may be necessary to construct unpaved roads that cross the washes in several places.	The Project will conform to the California State Water Resource Control Board (SWRCB) National Pollutant Discharge Elimination System (NPDES) General Permit for Storm Water Discharges (General Permit) for both construction and industrial (if applicable) activities regulations regarding runoff and erosion control, as well as applicable regional, county, and local requirements. This will include preparing a Storm Water Pollution Prevention Plan (SWPPP) for any discharges to Waters of the U.S., and implementing appropriate storm water BMP. BMPs will consist of control measures such as swales and ditches, stabilized construction entrances, gravel-covered construction staging area, and silt fencing. The industrial SWPPP (if necessary) will include appropriate BMPs (such as secondary containment structures around mineral oil-filled transformers).

APPENDIX A
ENVIRONMENTAL CONSIDERATIONS
Desert Quartzite Solar Project

Resources	Project Effects on the Resource	Environmental Protection Measures
Ground Water	If available, ground water may be used for the Project.	Use of groundwater resources, if available, will be designed, so that there are no adverse impacts to groundwater levels or concentrations.
Surface Discharge	Project surface flows will remain similar to the existing natural surface flows. .	None
Water Supply/Water Use (Construction)	It is expected that water will be collected from on-site wells to meet water needs during construction (e.g., concrete foundations, equipment pads, and dust control).	Use of groundwater resources, if available, will be designed, so that there are no significant impacts to groundwater levels or concentrations.
Water Supply/Water Use (Operational)	During operation, the Project will consume small amounts of water, which are expected to come from on-site wells.	None
Visual Resources		
Lighting	Lights may periodically be used at nighttime in occupied portions of the Project area for security purposes.	Lighting on the Project Site will be limited to areas required for operations or safety, will be directed on site to avoid backscatter, and will be shielded from public view to the extent practical. Lighting that is not required to be on during nighttime hours will be controlled with sensors or switches operated such that lighting will be on only when needed.
Color and Reflection	The Project will introduce new man-made facilities to the viewshed.	A paint color acceptable to the BLM will be used on all Project facilities that can be painted where appropriate to blend more naturally with the existing setting. Any necessary fencing will be constructed of non-reflective materials or will be treated or painted to reduce visual effects on sensitive viewing areas. The reflectivity of surfaces will be reduced by using non-reflective elements where appropriate and possible.

APPENDIX A
ENVIRONMENTAL CONSIDERATIONS
Desert Quartzite Solar Project

Resources	Project Effects on the Resource	Environmental Protection Measures
Profile	The Project's PV blocks will cover an extensive ground area with dark PV panels, which will result in a visual impact. As the Project will be situated on nearly flat land on only slightly elevated terrain, only portions of the Project area will be visible at middle distances from the major roads in the area. Because the Project will be located near I-10 some visual buffer setback will be provided, the distance to be determined in the NEPA process	The Project area will use low profile PV panel structures that should not extend higher than approximately 6 feet above the ground surface. Project facilities will be set back approximately ½ mile from I-10. Visual Impact Analyses of the potential visual impact of the project will be conducted as part of the Project EIS.
Geological, Soils, & Mineral Resources		
Geologic Hazards	The Project buildings and other facilities will be constructed in a seismically active area.	The development facilities would be built in accordance with Riverside County Building Code requirements applicable to Seismic Zone 4. No human occupied structures will be placed across the trace of an active fault, and no human occupied structure will be placed within fifty feet of the trace of an active fault or within a seismic special studies zone without a geologic report, satisfactory to the State Geologist, demonstrating that no undue hazard would be created by the construction or placement of the structure.
Minerals	No commercial quantities of saleable or leasable minerals are known to exist within the Project Site.	None
Soils	Soils will be disturbed during site construction and along access ways during normal operations.	See air quality fugitive dust control measures.
Public Health and Safety		
Hazardous Waste	No hazardous wastes will be used or generated by the Project during normal operations.	Not Applicable
Petroleum Hydrocarbon Waste	Bulk containers of petroleum hydrocarbon fuels may be located in the construction staging area and used during site construction to fuel vehicles.	Bulk fuel containers will be stored in secondary containment to catch any potential fuel spills. Spilled petroleum hydrocarbon wastes will be collected and transported to an offsite disposal facility authorized to accept the wastes.

APPENDIX A
ENVIRONMENTAL CONSIDERATIONS
Desert Quartzite Solar Project

Resources	Project Effects on the Resource	Environmental Protection Measures
Solid Waste	Solid wastes will be generated during the construction phases of the Project. Minimal amounts of solid waste will be generated during the operational phase of the Project.	Solid wastes generated by the Project will be temporarily stored in wind- and wildlife-secure containers on site. Solid wastes generated by the Project will be transported to an offsite disposal facility authorized to accept the wastes.
Sanitary Waste	Sanitary waste will be generated during both construction and operational phases of the Project.	During site construction portable sanitary facilities will be located in the Project area and maintained by a local contractor. During the operational phase of the Project either portable sanitary facilities will continue to be used and/or a septic system will be constructed for the Operations and Maintenance facility.
Socioeconomics and Environmental Justice		
Socioeconomics (During Construction)	During Project construction, the workforce is expected to average approximately 600 employees over the 18 to 48 month construction period, with a peak workforce of approximately 1,000 employees. The Project construction workforce will be recruited from within Riverside County and elsewhere in the surrounding region as much as practicable. A temporary increased demand for services from local businesses, employment opportunities, and increased demand for temporary housing will likely occur.	None
Socioeconomics (During Operations)	During the operational phase of the Project, the social and economic effects are likely to be minimal. The Project will employ up to 15 maintenance and security workers and have minimal demand on local services. The Project will generate approximately 300 MW of renewable energy for sale to California utilities.	None

APPENDIX A
ENVIRONMENTAL CONSIDERATIONS
Desert Quartzite Solar Project

Resources	Project Effects on the Resource	Environmental Protection Measures
Environmental Justice	There are no known minority groups or disadvantaged populations living within or adjacent to Project area that would be disproportionately affected by the Project.	None
Rangeland and Livestock		
Rangeland and Livestock	No public rangelands are known to occur in the Project vicinity and no range allotments have been issued by the BLM for lands within or near the Project area.	Not Applicable
Noise		
Noise	The Project will generate noise during construction; however, the closest noise sensitive resources are located more than one mile from the Project site. The Project should not generate noise during normal operations that would adversely affect dispersed recreation in the Project vicinity.	None

Appendix B Preliminary Biological Resources Assessment

A draft Biological Resources Technical Report for the Desert Quartzite Solar Project has been prepared and submitted to the BLM in 2014 for review as discussed in Section 6.1 of the POD. Once the BLM's review is completed, the report will be finalized and considered in the EIS and permitting for the Project, as appropriate.

IMPORTANT NOTE: Are the BLM land use designations (also called "Multiple-Use Class" available (e.g., Controlled Use, Limited Use, Moderate Use, and Intensive Use)? There are the key land uses that need to be shown in the Study Area. These designations for the Project are would likely be found associated with the BLM California Desert Conservation Area (CDCA) Plan.
Within the BLM jurisdictional areas including the entire Project Study Area, the BLM land use designations are only applicable (i.e., the County's land use designations have no worth on BLM land). Therefore, if need be, the County's LU designations in these areas can be blocked

LEGEND

SPECIAL FLOOD HAZARD AREAS (SFHAs) SUBJECT TO INUNDATION BY THE 1% ANNUAL CHANCE FLOOD

The 1% annual chance flood (100-year flood), also known as the base flood, is the flood that has a 1% chance of being equaled or exceeded in any given year. The Special Flood Hazard Area is the area subject to flooding by the 1% annual chance flood. Areas of Special Flood Hazard include Zones A, AE, AH, AO, AR, A99, V and VE. The Base Flood Elevation is the water-surface elevation of the 1% annual chance flood.

ZONE A No Base Flood Elevations determined.

ZONE AE Base Flood Elevations determined.

ZONE AH Flood depths of 1 to 3 feet (usually areas of ponding); Base Flood Elevations determined.

ZONE AO Flood depths of 1 to 3 feet (usually sheet flow on sloping terrain); average depths determined. For areas of alluvial fan flooding, velocities also determined.

ZONE AR Special Flood Hazard Area formerly protected from the 1% annual chance flood by a flood control system that was subsequently decertified. Zone AR indicates that the former flood control system is being restored to provide protection from the 1% annual chance or greater flood.

ZONE A99 Area to be protected from 1% annual chance flood by a Federal flood protection system under construction; no Base Flood Elevations determined.

ZONE V Coastal flood zone with velocity hazard (wave action); no Base Flood Elevations determined.

ZONE VE Coastal flood zone with velocity hazard (wave action); Base Flood Elevations determined.

FLOODWAY AREAS IN ZONE AE

The floodway is the channel of a stream plus any adjacent floodplain areas that must be kept free of encroachment so that the 1% annual chance flood can be carried without substantial increases in flood heights.

OTHER FLOOD AREAS

ZONE X Areas of 0.2% annual chance flood; areas of 1% annual chance flood with average depths of less than 1 foot or with drainage areas less than 1 square mile; and areas protected by levees from 1% annual chance flood.

OTHER AREAS

ZONE X Areas determined to be outside the 0.2% annual chance floodplain.

ZONE D Areas in which flood hazards are undetermined, but possible.

COASTAL BARRIER RESOURCES SYSTEM (CBRS) AREAS

OTHERWISE PROTECTED AREAS (OPAs)

CBRS areas and OPAs are normally located within or adjacent to Special Flood Hazard Areas.

Floodplain boundary

Floodway boundary

Zone D boundary

CBRS and OPA boundary

Qw	Alluvium of modern washes (Holocene)
Qr	Alluvium of the modern Colorado River flood plain (Holocene)
Qp	Playa lake deposits (Holocene)
Qs	Eolian sand (Holocene)—Brown lines mark dune crests
	Alluvial-fan and alluvial-valley deposits (Holocene to Miocene)
Qa_6	Unit 6 (Holocene)
Qa_5	Unit 5 (Holocene)
Qa_4	Unit 4 (Holocene and Pleistocene)
Qa_3	Unit 3 (Holocene and Pleistocene)
QTa_2	Unit 2 (Pleistocene to Miocene)
Ta_1	Unit 1 (Miocene)
	Alluvial deposits of the ancestral Colorado River (Pleistocene and Pliocene)
Qpv	Alluvial deposits of Palo Verde Mesa (Pleistocene)
Qbm	Alluvial deposits east of the Big Maria Mountains (Pleistocene)
Qbmg	Gravel-dominated deposits
Qbms	Sand-dominated deposits
QTmm	Alluvial deposits of the Mule Mountains (Pleistocene or Pliocene)
QTmw	Alluvial deposits of the McCoy Wash area (Pleistocene and/or Pliocene
QTe	Alluvial deposits of the Ehrenberg area (Pleistocene and/or Pliocene)
QTes	Sand-dominated deposits
	Bouse Formation (Pliocene and/or Miocene)
Tbs	Fine-grained clastic sedimentary rocks
Tbl	Limestone
Tbx	Sedimentary breccia (Miocene and Oligocene?)
Tsb	Slide blocks (Miocene and Oligocene?)
Tfbx	Fanglomerate, sedimentary breccia, and slide blocks, undivided (Mioc and Oligocene?)
Ti	Felsic intrusive rocks (Miocene and Oligocene?)
Tv	Volcanic rocks (Miocene and Oligocene?)
Kgp	Gneissic porphyritic granite (Cretaceous)
Ka	Andesite (Cretaceous or Jurassic)
	McCoy Mountains Formation (Cretaceous and Jurassic?)
Kml	Member L (Cretaceous)
Kmk	Member K (Cretaceous)
Kmj	Member J (Cretaceous)
Kmi	Member I (Cretaceous)
Kmh	Member H (Cretaceous)
Kmg	Member G (Cretaceous)
Kmf	Member F (Cretaceous)
Kme	Member E (Cretaceous)
Kmd	Member D (Cretaceous)
Kmc	Member C (Cretaceous)
KJmb	Member B (Cretaceous or Jurassic)
KJma	Member A (Cretaceous or Jurassic)
JTu	Volcanic and sedimentary rocks, undivided (Jurassic and Triassic)
Jv	Volcanic rocks (Jurassic)
Jp	Plutonic rocks (Jurassic)
Jpgd	Foliated granodiorite and diorite
Jpgb	Hornblende gabbro
JTrs	Sedimentary rocks (Jurassic and Triassic)
Trqm	Quartz monzonite and monzodiorite (Triassic)
Trd	Diorite and gabbro (Triassic?)
PzS	Sedimentary rocks, undivided (Paleozoic)
P€s	Sedimentary rocks (Permian to Cambrian)
PIPs	Sedimentary rocks (Permian and Pennsylvanian)
M€s	Sedimentary rocks (Mississippian to Cambrian)
Xpg	Porphyritic granite and augen gneiss (Proterozoic)
Xgn	Gneiss and amphibolite (Proterozoic)
	UNITS OF MIXED OR UNCERTAIN AGE
MzPgn	Gneissic rocks, undivided (Mesozoic and Proterozoic)
MzPs	Schist (Mesozoic or Proterozoic)
MzPfg	Fine-grained gneiss (Mesozoic or Proterozoic)

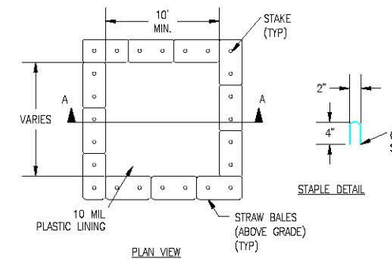
NOT TO SCALE



NOTES:

1. PREPARE THE SLOPE BEFORE THE WATTLING PROCEDURE IS STARTED.
2. DIG SMALL TRENCHES ACROSS THE SLOPE ON CONTOUR, TO PLACE ROLLS IN. THE TRENCH SHOULD BE DEEP ENOUGH TO ACCOMMODATE HALF THE THICKNESS OF THE ROLL, WHEN THE SOIL IS LOOSE AND UNCOMPACTED, THE TRENCH SHOULD BE DEEP ENOUGH TO BURY THE ROLL 2/3 OF ITS THICKNESS BECAUSE THE GROUND WILL SETTLE.
3. INSTALL ROLLS PERPENDICULAR TO WATER MOVEMENT.
4. START AT THE BOTTOM OF THE SLOPE AND WORK UP.
5. CONSTRUCT TRENCH AT CONTOUR INTERVALS OF 12 FEET APART.
6. USE STRAIGHT BAR TO DRIVE HOLES THROUGH THE WATTLE AND INTO THE SOIL.
7. MAKE SURE NO GAPS EXIST BETWEEN THE SOIL AND THE STRAW WATTLE.
8. DRIVE THE STAKE THROUGH THE PREPARED HOLE INTO THE SOIL. LEAVE ONLY 1 OR 2 INCHES OF STAKE EXPOSED ABOVE ROLL. INSTALL STAKE EVERY 4 FEET APART THROUGH THE WATTLE. ADDITIONAL STAKES MAY BE DRIVEN ON THE DOWNSLOPE SIDE OF THE TRENCHES ON HIGHLY EROSIVE OR VERY STEEP SLOPES.
9. RUNOFF MUST NOT BE ALLOWED TO RUN UNDER OR AROUND ROLL.

4 FIBER ROLL

NOT TO SCALE

Re: Preliminary Geotechnical Investigation Report
Desert Quartzite Solar Project (CACA 04937)
Riverside County, California
Township 7 South, Range 21 East, San Bernardino Baseline and Meridian

Dear Mr. Cook:

URS Corporation (URS) is pleased to present the results of our preliminary geologic/geotechnical investigation performed for the proposed site development at the Desert Quartzite Solar Project, located in Riverside County, California. The preliminary conclusions and recommendations contained in this report are based on the findings of our literature review and our interpretation of the site geologic and geotechnical conditions based upon this literature review. The purpose of this investigation was to evaluate the geologic/geotechnical constraints to the development of the property. Further site-specific geotechnical investigation, including field investigation, will be required for the final design phase of the project.

Should you have any questions or require additional information, please do not hesitate to contact Robert Urban at 805-361-1109.

Sincerely,
URS Corporation

EXECUTIVE SUMMARY

This geotechnical assessment executive summary has been prepared to provide a general overview of the report. The executive summary should be used in conjunction with the entire report for design and/or construction purposes. It should be recognized that specific details were not included or fully developed in this section, and the report must be read in its entirety for a comprehensive understanding of the sections discussed herein.

The Desert Quartzite Solar Project (Site) is located in eastern Riverside County approximately 8 miles southwest of the town of Blythe, California. First Solar Development, Inc. (First Solar) proposes to construct and operate a solar photovoltaic energy-generating project at the Site. The proposed project will include the solar facility, an on-site substation, and an interconnection transmission line (gen-tie) to Southern California Edison's (SCE) Colorado River Substation to the west of the site.

The primary objective of this preliminary geotechnical investigation was to identify potential geologic and geotechnical issues for the Project development. The scope of work performed by URS included a review of readily available information and data on the geotechnical and geological conditions of the project area and preparation of this report.

Based on information obtained from the preliminary review, the Site appears to be suitable for development for the proposed project. A comprehensive geotechnical report should be prepared prior to construction with recommendations to be incorporated into the final design.

The most significant geologic hazard to the project identified in this preliminary study is the potential for moderate seismic shaking likely to occur during the design life of the proposed development. The project Site is located in the seismically active Southern California region within the influence of several fault systems considered to be potentially active. Structures should be designed in accordance with the values and parameters provided in the 2007 California Building Code (CBC) and ASCE 7-05. The preliminary seismic design parameters are provided within the report.

A comprehensive design-level geotechnical investigation should be performed prior to construction. Earthwork on the project should be observed and evaluated by a licensed engineer practicing in the field of geotechnical engineering. The evaluation of earthwork should include observation and testing of engineered fill, subgrade preparation, foundation bearing soils, and other geotechnical conditions exposed during construction.

.

SECTION 1.0
INTRODUCTION

1.1 BACKGROUND

First Solar Development, Inc. (First Solar) is considering development of the Desert Quartzite Solar Project (Site), located in eastern Riverside County approximately 10 miles southwest of the town of Blythe, California. Consequently, First Solar retained URS to conduct a preliminary geotechnical investigation to support planning and permitting activities relative to this project. The primary objective of the preliminary investigation was to identify potential geologic and geotechnical issues for the Project development, and to provide geologic/geotechnical information to support the Bureau of Land Management's permitting process for the project.

1.2 SCOPE OF WORK

This investigation is based on a review of readily available information and data on the geotechnical and geological conditions of the project area. The tasks performed for this investigation included the following:

- Review of First Solar's development plans
- Review of available pertinent literature and reports
- Preparation of this report

The primary information available for this study included published regional geologic maps and reports.

1.3 SITE LOCATION AND DESCRIPTION

The Site is approximately 7.5 square miles in size and is located south of U.S. Interstate 10 (I-10), approximately 10 miles southwest of the town of Blythe, California (Figure 1). The Site comprises approximately 4,769 acres located within Sections 3, 4, 9 through 15, 22, 23, and 24, Township 7 South, Range 21 East, San Bernardino Baseline and Meridian.

The Site is situated on the Palo Verde Mesa located within the Mojave Desert geomorphic province of Southern California. The Site is located on a relatively flat area and ranges in elevation from approximately 330 feet above mean sea level (MSL) at the southeast corner to 475 feet MSL in the northwest (USGS 1983). The Palo Verde Mesa is located south of the McCoy Mountains, west of the Palo Verde Valley, north of the Palo Verde Mountains, and northeast of the Mule Mountains.

1.4 PROPOSED DEVELOPMENT

First Solar proposes to construct and operate an approximately 300 megawatt (MW) solar photovoltaic energy facility at the Site. The proposed project includes the following key structures: solar field arrays, an on-site operation and maintenance facility, an on-site substation, and an interconnection transmission line (gen-tie) to SCE's Colorado River Substation. The proposed project Site boundary, including the proposed gen-tie corridor, is shown on Figure 1 (topographic map) and Figure 2 (aerial map). URS understands that the development plans are preliminary in nature and subject to refinement.

SECTION 2.0
GEOLOGIC SETTING

2.1 REGIONAL GEOLOGIC AND SEISMIC SETTING

The project site is located on the Palo Verde Mesa within the Mojave geomorphic province of southern California. The Mojave Desert is a broad interior fault-bounded wedge consisting of pre-Cambrian gneisses, metamorphosed sedimentary rocks, plutonic rocks, scattered Mesozoic-age volcanics and metavolcanics, and sedimentary strata. The Mojave Desert is bounded by the right-lateral San Andreas fault on the south, the left-lateral Garlock fault on the northwest, and the Colorado River on the east (DMG 1954) and is characterized by isolated mountain ranges separated by vast expanses of desert plains. Dominant northwest-southeast trending faults control topography in this region.

The area surrounding the site is characterized by faults and seismicity driven by movement along the boundary between the North American and Pacific crustal plates. These two plates are passing by each other horizontally, in a right lateral sense (i.e., the North American plate is moving southeastward relative to the Pacific plate) at a rate of about 40 to 50 millimeters (mm)/year. Most of this stress is accommodated by movement on the San Andreas fault, which extends from north of San Francisco to the Gulf of California and marks the southern boundary of the Mojave Desert geomorphic province. The San Andreas fault presents significant seismic risk to California with a high potential for large earthquakes.

The remaining portion of the crustal stress is accommodated by the numerous shorter active faults that flank the San Andreas fault. These shorter faults are also considered to be significant seismic sources. The geoseismic characteristics of these seismic sources are summarized in Section 2.3, including an estimate of the maximum earthquake magnitude that might be generated by each fault. A geologic map is depicted on Figure 3. The location of the site with respect to known active or potentially active faults and epicenters of earthquakes with magnitudes of 4 or greater is shown on the Regional Fault and Epicenter Map, Figure 4.

2.2 GENERAL SITE GEOLOGY

The Palo Verde Mesa is characterized by the nearly level morphology of the mesa and gently to moderately sloping alluvial fans. Fluvial erosion and deposition are the major geomorphic processes in the immediate area. According to the regional geologic mapping of Jennings (CGS 1967), the northern portion of the project site is underlain by metamorphosed sedimentary bedrock of Pre-Cretaceous age. The Cretaceous Period is a geologic period extending from approximately 145 to 65.6 million years ago (Ma). Southwest of the Site, the metamorphosed sedimentary bedrock of Pre-Cretaceous age (greater than 145 Ma) abuts Precambrian age (4,600 to 542 Ma) granitic bedrock. Based on the Jennings' fault activity mapping (CGS 1994), this unconformity is a pre-Quaternary age (2.6 Ma to present) thrust

fault system trending northwest immediately southwest of the Site. Stone (USGS 2006) identifies the bedrock types as Jurassic age (199 to 145 Ma) volcanics north of the thrust fault and Jurassic age (199 to 145 Ma) plutonic rocks to the south (USGS 2006). Both Jennings (CGS 1994) and Stone (USGS 2006) map a thrust fault in the same place; however, Jennings' map includes additional fault traces. The Jennings 1994 CGS map identifies a Tertiary age (65 to 2.6 Ma) fault southwest of the site; however, a recent map developed by the USGS depicts detailed Quaternary age (2.6 Ma to present) terrace mapping which identifies terraces of varying ages rather than an offset single terrace that has been offset due to faulting (USGS 2006).

Overlying the Precambrian to Mesozoic age bedrock immediately southwest of the Site are Tertiary age (65 to 2.6 Ma) volcanics of rhyolitic composition (CSG 1994; USGS 2006). These volcanics are of Oligocene age (34 to 23 Ma) to Miocene age (23 to 5.3 Ma), indicating the depositional event(s) took place between 5.3 and 34 million years before present, coinciding with a period of intense plate tectonic activity. In the southeastern corner of the Site, the bedrock is overlain by Pleistocene age (2.6 Ma to 11,700 years before present [BP]) non-marine sediments. Holocene age (11,700 BP to present) alluvium overlays the older units across most of the Site; according to Stone (USGS 2006), the alluvium overlying the western portion of the Site is of Pleistocene age (2.6 Ma to 11,700 BP). Deposits of Holocene age dune sand are present in the northwestern portion of the Site (11,700 BP to present), including along the off-site portion of the gen-tie corridor. The distribution of these various units is depicted on the attached Geologic Map (Figure 2). The general characteristics of each of these geologic map units are described below in the relative order of predominance on the Site, including the proposed gen-tie corridor.

2.2.1 Quaternary Non Marine (Qpv)

Pleistocene age (2.6 Ma to 11,700 BP) alluvial deposits of the ancestral Colorado River comprised of moderately indurated, poorly graded sand, gravel, boulders, silt, and clay.

2.2.2 Quaternary Alluvium (Qa_6)

Holocene age (11,700 BP to present) alluvial fan and alluvial valley deposits comprised of unconsolidated sand, gravel, silt, and clay.

2.2.3 Quaternary Dune Sand (Qs)

Holocene Age (11,700 BP to present) dune sand comprised of actively drifting sand.

2.2.4 Quaternary Alluvium (Qa_3)

Holocene and Pleistocene age (2.6 Ma to present) alluvial fan deposits comprised of unconsolidated sand, gravel, silt, and clay.

2.2.5 Quaternary Alluvium (Qw)

Holocene Age (11,700 BP to present) alluvium of modern washes comprised of unconsolidated sand and gravel derived from local mountain ranges.

2.3 FAULTS

There are no known faults active during the Quaternary located in the Palo Verde Mesa area. The Jennings (CGS 1994) map identifies a Tertiary age (65 to 2.6 Ma) fault southwest of the Site; however, a recent map developed by the USGS depicts detailed quaternary terrace mapping which identifies terraces of varying ages rather than an offset single terrace (CGS 1994; USGS 2006).

The approximate distances of active fault zones from the Site are listed in Table 1.

TABLE 1
SUMMARY OF POTENTIAL SEISMIC SOURCES –
FAULTS IN PROXIMITY TO SITE

Fault Name	Approximate Distance from Site (Miles)
Brawley Seismic Zone	58.8
Elmore Ranch	59.2
San Andreas – Southern	59.7
San Andreas – Coachella	59.7
Imperial	66.7
Superstition Hills (San Jacinto)	71.0
Superstition Mountain (San Jacinto)	73.8
Pinto Mountain	81.7
San Jacinto – Borrego	82.3
San Jacinto – Anza	84.1
Pisgah-Bullion Mountain – Mesquite LK	84.6
Laguna Salada	89.0
San Jacinto – Coyote Creek	89.2
Elsinore – Coyote Mountain	92.3
Emerson So. – Copper Mountain	94.3

Eureka Peak	97.9
Burnt Mountain	99.7

2.4 NRCS SURFACE SOILS INFORMATION

Based on review of the U.S. Department of Agriculture (USDA), Natural Resource Conservation Service (NRCS) (previously Soil Conservation Service) soil survey of the Palo Verde Area, the Site is characterized by multiple soil types, generally consisting of silty sands and gravels (USDA 1969). The NRCS mapped soil types at the Site are listed in Table 2. Figure 5 depicts the distribution of soils at the Site.

TABLE 2
NRCS SURFACE SOILS PROPERTIES AND DESCRIPTION

Soil Series	Slope (% Grade)	Depth (Inches)	Classification USCS[1]	Classification AASHTO[2]	Description
Aco	0–1	0–60	SM	A-1, A-2	The Aco series comprises deep, well-drained soil formed in mixed alluvium on terraces above the flood plain.
Carrizo	0–2	0–60	SW-SM, GM	A-1	The Carrizo series comprises deep, well-drained soils formed in mixed sandy and gravelly alluvium on arroyos.
Chuckwalla	0–1	0–60	GC-GM	A-1, A-2, A-4	The Chuckwalla series comprises deep, well-drained soils formed in mixed stratified alluvium on alluvial fan terraces.
Orita	0–1	0–80	SM, GM	A-1, A-2, A-4, A-6	The Orita series comprises deep, well drained soils formed in alluvium on alluvial fan remnants and terraces.
Rositas	0–9	0–72	SM, SP-SM	A-1, A-2, A-3	The Rositas series comprises deep, well-drained soils formed in sandy eolian soils from recent alluvium on sand dunes.

1 USCS: United Soils Classification System.

2 AASHTO: American Association of State Highway and Transportation Officials classification.

The Aco series is present throughout the Site and is the predominant soil type on the Site. All of the soils mapped on Site have low potential for expansive soil characteristics, according to the Palo Verde Area soil map (USDA 1969).

As shown on Figure 5, other soil series prevalent on the Site include the Orita and Rositas series as well as the Carrizo series. The mapped soil series on the Site are considered to have high risk of corrosion for uncoated steel and low to moderate risk of corrosion for concrete. Based on the USDA report, there is a low to moderate potential for water- and wind-induced erosion for soil series throughout the Site (USDA 1969).

The USDA report provides an interpretation of soil limitations for septic suitability. Using these interpretations, all of the soil series mapped on the Site are classified as somewhat limited with respect to septic suitability with one exception; the Orita series is classified as very limited suitability for septic system disposal fields (USDA 1969).

2.5 GROUNDWATER CONDITIONS

The depth to groundwater in the Site vicinity is believed to be greater than 100 feet below ground surface (bgs) based on relative site elevation difference above the Colorado River and floodplain (Palo Verde Valley) and measured depth to groundwater at adjacent sites (DWR 1978; Metzger et al 1973). Groundwater levels may fluctuate seasonally with precipitation, regional pumping from wells, irrigation, drainage, and site grading.

SECTION 3.0
GEOLOGIC AND SEISMIC HAZARDS

Geologic and seismic hazards are those hazards that could impact the project due to the surrounding geologic and seismic conditions. Geological hazards include slope instability (landslides), erosion, subsidence, poor soil conditions, excessive settlement, and flooding. Seismic hazards include phenomena that occur during an earthquake such as surface fault rupture, seismic ground shaking, liquefaction, and tsunami waves. The potential impact of these hazards to the Site has been *assessed* and is summarized in the following sections.

3.1 FLOODING

The Site is located in an area designated Zone D within the Federal Emergency Management Agency (FEMA) Flood Insurance Rate Maps, indicating an area where there are possible but undetermined flood hazards (FIRM map 06065C Panel *06065C3200G). In areas designated Zone D, no analysis of flood hazards has been conducted.

The project Site is located in an arid environment and on relatively high ground northeast of the Mule Mountains, which drain into and through portions of the Site. Based on the TLA site drainage report (TLA 2011), the potential for flooding on the Site is considered moderate.

3.2 SLOPE INSTABILITY/LANDSLIDES

The potential for slope instability is insignificant based on the relatively flat terrain that characterizes the Site (USGS 1975; 1983). Therefore, the potential for hazards related to slope instability, landslides, or debris flows is considered low; however, considering the potential for flooding on Site, the hazard of episodic debris flows may be present based on Site hydraulic analysis (TLA 2011).

3.3 SUBSIDENCE

Land subsidence can be caused by various natural phenomena, including tectonic movement, hydro compaction, or consolidation. The extraction of water or petroleum from sedimentary source rocks can also cause the permanent collapse of the pore space previously occupied by the removed fluid. Sufficient subsidence resulting from these phenomena may cause damage to nearby engineered structures.

Based on review of available literature, subsidence has not been documented within the vicinity of the project site (USGS 2002; DWR 1978) and available literature does not indicate significant quantities of fluids being extracted in the project area. Subsidence is therefore not anticipated to pose a significant hazard to the proposed project.

3.4 POOR SOIL CONDITIONS (EXPANSIVE OR COLLAPSIBLE SOILS)

Expansive soils are fine-grained soils (clay) that can undergo a significant increase in volume with an increase in water content. Changes in the water content of an expansive soil can result in severe distress to structures constructed upon the soil. Based on USDA, NRCS soil maps and descriptions, the on Site surface and near-surface soils are expected to exhibit low expansive potentials. As expansive soils may impact a project, testing should be conducted to identify the degree to which onsite soils may expand.

Collapsible soils are those that undergo settlement upon wetting, even without the application of additional load. The process of collapse with the addition of water is known as hydrocompaction. Hydrocompaction occurs when water weakens or destroys the bonds between soil particles and severely reduces the bearing capacity of the soil. Typical collapsible soils are lightly colored, are low in plasticity and have relatively low densities. Collapsible soils are typically associated with alluvial fans, windblown materials, or colluvium. Because the project Site is largely covered in alluvium and windblown materials, the potential for collapsible soils may exist at the project Site. If collapsible soils are found to occur at the Site, as part of the design level geotechnical investigation mitigation measures may be necessary to reduce or eliminate the hazard. Traditional methods of construction grading generally would employ removal of collapsible soils and replacement with engineered fill. Provided that these mitigation methods are incorporated into the design of the project, collapsible soils are not expected to have a significant impact upon the project.

3.5 EXCESSIVE SETTLEMENT (ARTIFICIAL FILL)

A risk of excessive settlement can be associated with improperly placed and substandard artificial fills. With regard to this potential hazard, based on aerial photograph review and available literature there is no evidence at this time of previous site disturbance which would entail artificial fill; therefore, it is unlikely that excessive settlement of artificial fill would have a negative impact on this project.

3.6 FAULT HAZARDS

3.6.1 Surface Fault Rupture

The “Alquist-Priolo Earthquake Fault Zoning Act” is a state law that regulates development projects near active faults to mitigate the hazard of surface fault rupture. The Act requires that development permits for projects within “Earthquake Fault Zones” be withheld until geologic investigations demonstrate that the sites are not threatened by surface displacement from future fault rupture. To be zoned under the Alquist-Priolo Fault Zoning Act, a fault must be considered active or both sufficiently active and well-defined (CGS 1997). CGS defines an active fault as one that has had surface displacement within Holocene time (about the last 11,000 years), and a sufficiently active fault as one that has evidence of Holocene

surface displacement along one or more of its segments or branches (CGS 1997). The CGS considers a fault to be well defined if its trace is clearly detectable as a physical feature at or just below the ground surface.

The State of California has not yet completed mapping the region in which the Site is located for Seismic Hazard Zones. No known active, sufficiently active, or well-defined fault traces have been recognized as crossing the proposed project Site, and the CGS does not delineate any part of the proposed project as being within an Earthquake Fault Zone.

3.6.2 Seismic Ground Shaking

As indicated by the numbers and distribution of recorded earthquake epicenters and the proximity of faults in the region (Figure 3), it is anticipated that the site will be subjected to seismic shaking during the lifetime of the development. The degree of shaking that is felt at a given site depends on the distance from the earthquake source, the type of subsurface material on which the project is situated, and topography. Based on the California Geological Survey interactive Seismic Hazard map (CGS 2008), the Peak Ground Acceleration with a 10 percent chance of exceedance in 50 years would be less than 0.1g. The effect of seismic ground motion to the planned development should be mitigated by proper building design, in accordance to 2007 California Building Code (CBC) and its current amendments. Building codes are designed to limit the degree of damage that would otherwise occur to an un-reinforced building. Additional geotechnical studies should be performed to develop final seismic design recommendations.

The Site is located in Southern California, a seismically active area. The magnitude and type of seismic hazard which may potentially affect the Site is dependent on both proximity to causative faults, and magnitude of seismic event. Table 3 presents distance of fault zones from the Site and the maximum credible earthquake (MCE), calculated using the EQFAULT program, which nearby seismic events may produce.

Based on these calculations, the peak ground acceleration at the Site for a 10 percent Probability of Exceedance in 50 years is estimated to be approximately 0.0373g.

3.7 LIQUEFACTION

Liquefaction is defined as significant and relatively sudden reduction in stiffness and shear strength of saturated sandy soils caused by a seismically induced increase in pore water pressures. Potential for seismically induced liquefaction exists whenever relatively loose, sandy soils exist with high groundwater level and/or potential for long duration, high seismic shaking. The susceptibility of a site to liquefaction is relative to water content, depth, and density of granular sediments as well as the frequency and magnitude of earthquakes in the surrounding area. When liquefaction occurs, the site can experience damage induced by permanent ground movements resulting in differential settlement.

TABLE 3
SUMMARY OF POTENTIAL SEISMIC SOURCES – PARAMETERS AND ESTIMATED EARTHQUAKES FOR REGIONAL FAULTS

		Estimated Maximum Credible Earthquake Event		
Fault Name	Approximate Distance from Site (Miles)	Maximum Earthquake Magnitude (MM[1])	Peak Site Acceleration (g[2])	Estimated Site Intensity (Mod. Merc.[3])
Brawley Seismic Zone	58.8	6.4	0.016	IV
Elmore Ranch	59.2	6.6	0.019	IV
San Andreas – Southern	59.7	7.4	0.037	V
San Andreas – Coachella	59.7	7.1	0.029	V
Imperial	66.7	7.0	0.022	IV
Superstition Hills (San Jacinto)	71.0	6.6	0.014	III
Superstition Mountain (San Jacinto)	73.8	6.6	0.013	III
Pinto Mountain	81.7	7.0	0.015	IV
San Jacinto – Borrego	82.3	6.6	0.010	III
San Jacinto – Anza	84.1	7.2	0.018	IV
Pisgah-Bullion Mountain – Mesquite LK	84.6	7.1	0.016	IV

Eureka Peak	97.9	6.4	0.006	II
Burnt Mountain	99.7	6.4	0.006	II

1 MM: moment magnitude.

2 g: acceleration due to earth's gravity.

3 Mod. Merc.: Modified Mercalli Intensity Scale.

Mitigation methods for liquefaction may include identifying potentially liquefiable soils and then either avoiding placing structures within the limits of liquefiable soils, or applying in-situ soil improvement, and using a deep foundation system. In-situ soil improvement methods for liquefiable soil include vibro-replacement, compaction grouting and deep soil mixing. A deep foundation system may consist of driven pre-cast piles or cast-in-drilled-hole piers or caissons. The results of the forthcoming detailed geotechnical investigation relative to liquefaction potential at the site should be incorporated into the final project design.

Based on the relatively deep water table underlying the Site, which is elevated over 100 feet above the floodplain of the Colorado River, the potential for liquefaction is considered to be low (USGS 1983; Metzger et al 1973).

3.8 TSUNAMIS AND SEICHES

A tsunami is a great sea wave (commonly called a tidal wave) produced by a significant undersea disturbance, such as tectonic displacement of the sea floor associated with large, shallow earthquakes. A seiche is a wave generated in an enclosed body of water such as a lake or reservoir. Based on the fact that the Site is situated inland, far from oceans or large, land-locked water bodies, the potential for seismically induced tsunamis or seiches is considered to be low (CGS 1977).

3.9 GENERAL SOIL EROSION AND STABILITY CONSIDERATIONS

The soils present at the Site have a low to moderate susceptibility to wind and water erosion (USDA 1969). Preventative measures to reduce seasonal flooding and erosion should be incorporated into site grading and drainage plans. Dust control should be implemented during construction, and soil stabilization measures should be implemented, where necessary.

The upper soils at the Site are expected to be relatively loose to medium-dense and may be unsuitable in their present condition to support structures in the vicinity of the operations and maintenance facility and the on-site substation. The soils within the building and structural areas may require moisture conditioning, over-excavation, and recompaction to improve bearing capacity and to reduce the potential for differential settlement from static loading. It is expected that these potential issues will be investigated as part of the forthcoming detailed geotechnical investigation and addressed, as applicable, in the final project design.

SECTION 4.0
SUMMARY

4.1 CONCLUSIONS AND RECOMMENDATIONS

The geology and seismic conditions of the project site have been evaluated in terms of their impact on the proposed project. Based on the findings of the preliminary site investigation, the project Site is generally suitable for the proposed development. Provided that standard geotechnical practices are followed and standard mitigation methods are incorporated into the final design of the development, it is anticipated that geologic hazards will not significantly impact the project. The primary geotechnical consideration for the project is the potential for moderate seismic shaking likely to occur during the design life of the proposed development. The project Site is located in the seismically active Southern California region within the influence of several fault systems considered to be potentially active. Structures should be designed in accordance with the values and parameters provided in the 2007 California Building Code (CBC) and ASCE 7-05. The seismic design parameters are provided within the report.

The published literature clearly indicates that the mapped faults near the Site are not active. Therefore, from a fault rupture hazard standpoint there is no requirement to establish a development setback zone for these faults.

Finally, URS notes that this is a preliminary assessment of engineering geologic/geotechnical conditions of the Site. For any given aspect of the development, final geotechnical conclusions and recommendations should be provided in a separate report after specific, final project plans are developed, and on-site geotechnical explorations and testing are performed.

4.2 LIMITATIONS

This report presents preliminary interpretations and recommendations pertaining to the subject site based on the assumption that surface and subsurface conditions do not deviate appreciably from those indicated by the available literature and reports (as cited in this preliminary report). The scope of this preliminary engineering geology and geotechnical investigation did not include any field investigations. The potential for encountering conditions different from those assumed cannot be discounted. Professional judgments presented in this report are based on evaluations of the available literature gathered, on our understanding of the proposed project construction, and on our general experience in the geotechnical engineering and engineering geology field. The judgments presented meet the standard of care of our profession at this time and location in work performed under similar circumstances.

1 EXECUTIVE SUMMARY

First Solar proposes to construct and operate a 300 Megawatt alternating current (MWac) solar photovoltaic energy generating facility known as Desert Quartzite Solar Project (Project). The Project is located on 5,000 acres in an unincorporated area of eastern Riverside County, south of Interstate 10 and west of Blythe, California. See Figure 1 for the Project vicinity map, Figure 2 for the Post Project site map and Figure 3 for the Project drainage shed map.

The purposes of this Report are to evaluate the Project's potential impact to drainage runoff depth, velocity, volume and sediment transport; determine the potential solar panel pedestal pier scour depths; and if necessary, propose mitigation measures for the identified Post Project drainage impacts.

The primary drainage criteria and methods follow the Riverside County Hydrology Manual. U.S Army Corps of Engineers HEC-1 modeling software was used to determine the mountain shed runoff hydrographs. FLO-2D modeling software was used to determine the alluvial fan area rainfall, flow depths, velocities, and sediment transport. HEC-18 method was used to determine the solar pedestal pier scour depths.

Based on the results of this Report, the proposed Desert Quartzite Solar Project will cause minor impacts to the existing drainage shed area. The impacts have been minimized due to the relatively flat terrain and presence of large natural depressions that range from one to five feet deep. These large depressions store significant volumes of water which attenuate the increased outflow. See Figure 4 for existing depression areas.

The unmitigated Post Project impacts during the 100-year storm event are as follows:

- Average Flow Depth increase of 0.03-feet
- Average Flow Velocity increase of 0.04 feet/second
- Total Outflow increase of 20 acre-feet (2.6%)

See Figures 5 and 6 for the maximum flow depth and velocity. The nominal Post Project increases in flow depth, velocity and outflow can be mitigated with onsite retention basins sized with at least 20 acre-feet of combined storm water storage capacity.

The unmitigated Post Project sediment transport will be less than the pre project conditions due to soil compaction. The Project site experiences relatively shallow and slow flows, so the nominal increases in Post Project flow depths and velocities do not overcome the decreased erosion potential due to compaction. See Figure 7 for maximum sediment scour depths.

The maximum potential pier scouring at the solar array pedestal supports is 1.22-feet. The structural design and embedment depth of the solar panel pedestal piers should account for the maximum potential scour plus a factor of safety. Monitoring after large storm events should be implemented to detect piers with significant scouring. See Figure 8 for pier scour depths.

AR060767

2 INTRODUCTION

First Solar proposes to construct and operate a 300 Megawatt alternating current (MWac) solar photovoltaic energy generating facility known as Desert Quartzite Solar Project (Project). The Project is located in an unincorporated area of eastern Riverside County, south of Interstate 10 and west of Blythe, California. The Project will be located on federal lands managed by the U.S. Department of Interior, Bureau of Land Management (BLM), Palm Springs Field Office. See Figure 1 for the Project vicinity map and Figure 2 for the Post Project site map.

The Project boundary encompasses 5,310 acres and will ultimately develop approximately 2,500 acres of solar panels. The Project facilities will consist of: fixed tilted solar panels mounted above ground on supports consisting of wide flange pedestals; access roads; underground electrical wires from solar panels, transformer pads; maintenance and control buildings and facilities; water well for potable water supply and onsite sewage disposal system for the maintenance building; electrical interconnect equipment; overhead phone line; and a transmission line and facilities.

The Project is located in an existing drainage alluvial fan area which receives drainage from offsite mountains and offsite alluvial fan areas. The offsite downstream areas consist of alluvial fan areas with drainage flows that ultimately drain over bluffs east of the Project site.

The drainage areas, including the Project, are located in ungauged watershed runoff areas.

FIRM maps for all of the drainage studied area, including the Project area, are designated in The FIRM Riverside County panel index sheet 06065CIND2A, dated August 28, 2008 as “Zone D”, “Areas in which flood hazards are undetermined”.

The purposes of this Report are:

1. Evaluate the Project’s potential impact to drainage runoff depth, velocity, volume and sediment transport;
2. Determine the potential solar panel pedestal pier scour depths; and
3. If necessary, propose mitigation measures for the identified Post Project drainage impacts.

AR060768

3 PROJECT SITE DESCRIPTION

The Project is located on largely undeveloped and relatively flat land on the Palo Verde Mesa in eastern Riverside County, approximately nine miles west of the City of Blythe and one mile south of the Interstate-10 freeway. See Figure 1 for the Project vicinity map.

The Project area is undeveloped except for the First Solar Electric Blythe 1 200-acre solar project abutting the northeast side of the Project; a portion of a developed subdivision located south of I-10 at the northeast side of the drainage shed studied; and overhead power line facilities that cross the drainage sheds studied. There are some areas in the alluvial fan area south of I-10 that were cultivated in the past. There also are some bermed areas in the alluvial fan that have evidently been constructed to divert drainage flows away from the internal areas protected by the berms. One of these bermed areas consists of a 160-acre parcel near the middle of and completely surrounded by the proposed Project.

3.1 Proposed Development

The Project will be a 300 Megawatt alternating current (MWac) solar photovoltaic energy generating facility. The Project will construct solar arrays, access roads, an on-site electrical substation, and maintenance facilities.

The photovoltaic (PV) modules are mounted on framing assemblies made of steel, each holding 16 modules and measuring approximately eight feet wide by sixteen feet long. The PV module assemblies are attached at an angle to vertical steel piers that are spaced eight feet center-to-center and are driven into the ground to a depth of four to seven feet below grade. Each steel pier is a single W6x7.2 “I” beam. Once mounted, the front of each PV module assembly will be approximately 1.5 feet above grade, while the rear will be approximately five to six feet above grade.

The PV modules are electrically connected by wiring harnesses running along the bottom of each assembly to combiner boxes that collect power from several rows of modules. The combiner boxes feed DC power from the modules to the Power Conversion Station (PCS) via underground cables. The inverters in the PCS convert the DC electric input into AC electric output and the isolation transformer steps the current up for on-site transmission of the AC power to the PV combining switchgear (PVCS). The PVCS collects the power for transmission to the substation.

3.2 Climate

The Riverside County Hydrology Manual describes the desert areas as extremely hot and dry during the summer months, with moderate temperatures occurring during the winter. The mean seasonal precipitation in the eastern desert region is three inches.

The region experiences three types of storms: general winter storms, general summer storms and high intensity thunderstorms. General winter storms generate most of the precipitation. As these

storms move toward the eastern end of the County, beyond the Santa Ana Mountains, little moisture remains and precipitation decreases rapidly over the desert areas.

3.3 Geology

The Project is located in an alluvial fan area with the Mule Mountains located immediately to the southwest and the McCoy Mountains located north of I-10. As discussed in the Riverside County Hydrology Manual, mountain areas have extremely shallow soil depths and on many of the steepest slopes soil cover is virtually non-existent with bedrock exposed. These areas without soil cover have extremely low infiltration capacity.

The alluvial cones and fans near the mountains have coarse soils and are extremely porous. The soils further downstream tend to become finer and less porous.

3.4 Soil Type

A geotechnical investigation by Earth Systems Southwest was performed on the First Solar Electric Blythe 1 200-acre solar project abutting the northeast side of the Project. This report indicates the soil conditions consist generally of medium dense to dense, dry to damp, fine to course grained Silty Sands and Sands with Some Silt (Unified Soils Classification System symbols SM and SP-SM).

Additionally, soil maps from the U.S. Department of Agriculture Natural Resources Conservation Service were obtained and evaluated to determine the various soil types within the alluvial fan area. These soils maps were used to calculate a composite runoff index number from the Riverside County Hydrology Manual Plate E-6.1.

3.5 Drainage Area

The existing drainage areas surrounding the Project were determined from a combination of USGS topographic maps and a project specific topographic survey performed by Hillwig-Goodrow, Inc. in 2009. Hillwig-Goodrow's survey utilized aerial Lidar scanning, ground survey control and conventional photogrammetry to generate one-foot elevation contours within the Project boundary. The drainage basins are shown on Figure 3.

There are two mountain areas that drain into and through portions of the Project that created the alluvial fan area.

One area is north of Interstate 10, and is designated as drainage shed M1 on Figure 3. This shed consists of a portion of the McCoy Mountains and a portion of alluvial fan that has been blocked and diverted to the southeast side of shed M1 by channelization and I-10. This shed consists of 3,343-acres and ranges in elevation from 1670-feet at the northwest corner to 470-feet at the southeast and the I-10 bridge crossing. The area drains under an I-10 bridge into an area south of the I-10 bridge and into the alluvial shed area north of the Project.

The other mountain area is towards the southwest side of the Project and consists of 27 sheds designated as sheds M2 through M28 on Figure 3. These sheds consist of a portion of the Mule Mountains that drain into the alluvial fan area west of the Project site. These 27 sheds have a cumulative acreage of 2,043-acres and range in elevations from 1750-feet to 395-feet where they enter into the alluvial fan.

The alluvial fan drainage area studied consists of the offsite and onsite areas and is located in the Palo Verde Mesa. The area consists of 14,847 offsite acres and 5,310 Project onsite acres for a total of 20,157-alluvial fan acres. The total alluvial fan area ranges in elevation from the highest elevation near the northwest of 525-feet to a lowest elevation of 320-feet near the southeast. The straight line length between these elevations is approximately 6.92-miles and yields a slope of 0.0056 feet/foot.

The northern portion of the alluvial fan can be considered inactive because of the construction of I-10 and the diversion of mountain shed's M1 and alluvial fan drainage to the I-10 bridge as a concentrated flow under the bridge. This concentrated flow eventually becomes braided south of I-10 and reenters the alluvial fan drainage area near the north side of the Project.

4 HYDROLOGIC ANALYSIS

The primary drainage criteria and methods follow the Riverside County Hydrology Manual for precipitation, soil infiltration, and runoff index numbers. The drainage shed areas that affect the Project upstream and that the Project may affect downstream are shown on Figure 3.

The total drainage shed area studied is approximately 25,543 acres (39.91 square miles) and consists of:

1. Mountain shed M1, north of the Project and I-10: 3,343 acres
2. Mountain sheds M2-M28 southwest of the Project: 2,043 acres
3. Alluvial fan area south of I-10:
   a. Outside of Project 14,847 acres
   b. Project area 5,310 acres

4.1 Precipitation

The Riverside County Hydrology Manual relies on the National Oceanic and Atmospheric Administration (NOAA) for precipitation. NOAA Atlas 14 was utilized for determining point precipitation frequency estimates for the 100-year event.

Point precipitation for four representative locations throughout the total drainage shed areas studied were obtained. The unadjusted point frequencies for the four locations were tabulated and found to have very little difference by location. Thus, the average of the four locations was calculated for each time period within the 24-hour rainfall event.

A rainfall distribution is not specified in the Riverside County Hydrology Manual; therefore, the point precipitation was adjusted per the San Bernardino County Hydrology Manual by the respective drainage shed areas. Lag times were calculated using the curve number method (i.e. runoff index number).

The resultant 100-year, 24-hour rainfalls for the drainage sheds are:

- mountain shed M1 = 3.47” (adjusted for area)
- mountain sheds M2-M28 = 3.50” (unadjusted because shed areas are less than 1 sq. mile)
- alluvial fan = 3.40” (adjusted for area).

4.2 Infiltration

The Riverside County Hydrology Manual estimates infiltration rates based on the watershed’s soil-cover complex. This estimation is expressed as an index of runoff potential or “runoff index” number ranging from zero to 100. High runoff index numbers indicate a high runoff potential with low infiltration.

AR060772

Riverside County specifies an antecedent moisture condition II for 100-year design storm events. Accordingly, Riverside County Plate E-6.1 provides the associated runoff index numbers.

The mountain shed areas have the following drainage shed characteristics:

1. Are undeveloped with Barren ground cover conditions;
2. For AMC II condition have a composite runoff index number:
    a. For mountain shed M1: RI = 88.5
    b. For mountain sheds M2-M28: RI = 93.0
3. Have a basin surface roughness coefficient "n" = 0.04;

The existing alluvial fan shed area has the following drainage characteristics:

1. Is mostly undeveloped with Barren ground cover conditions;
2. For AMC II condition has a composite runoff index number of 83.0;
3. Has a basin surface roughness coefficient "n" = 0.05;
4. Soil grading curve (using FSE Blythe1 geotechnical report) provides the following:
    a. D10 = 0.070 mm
    b. D50 = 0.270 mm
    c. D60 = 0.297 mm
    d. D95 = 2.700 mm
    e. Uniformity coefficient = D60/D10 = 4.24
    f. Specific gravity = 2.65
    g. Dry weight = 104 pounds/cubic feet

5 HYDRAULIC ANALYSIS

Because the proposed Project is located in ungauged watersheds with a large alluvial fan area, ephemeral drainages, and for most of the site not well defined drainage outlet channels, it is necessary to utilize several types of drainage technologies and methods in order to provide the information, results, and develop mitigation measures if needed.

U.S Army Corps of Engineers HEC-1 modeling software was used to determine the mountain shed runoff hydrographs. FLO-2D modeling software was used to determine the alluvial fan area rainfall, flow depths, velocities and sediment transport.

The hydrographs from the HEC-1 calculations were entered into the FLO-2D model and used along with the other parameters developed above for the alluvial fan area to calculate: maximum flow depths, maximum velocities and sediment aggregation/degradation depths. The FLO-2D model grid cells were set to dimensions of 300-feet by 300-feet.

FLO-2D output for maximum depths, velocities, and pier scour calculations are those that occurred at any time during the 36-hour runoff calculation period in each grid and they do not necessarily occur at the same time. Sediment aggregation/degradation amounts are those final amounts that result from the 100-year, 24-hour storm at the end of the 36-hour calculation period.

5.1 Pre to Post Project Characteristics

The Project will alter the soil's hydraulic characteristics within the solar arrays due to vegetation removal and grading as follows:

> Vegetation would not be removed from the Proposed Project site until the onset of construction of a given phase. Vegetation would be Disked under, mulched or composted and retained on site to assist in erosion control and limit waste disposal. In some areas to be graded outside of the solar field, native vegetation would possibly be harvested for replanting to augment soil stabilization.
>
> Area's comprising the solar array field will be prepared using conventional farming equipment including tractors with Disking equipment and vibratory rollers with limited use of scrapers to perform micrograding within sections of the solar array field. This method improves construction worker safety by eliminating trip hazards. The site will be contour graded level; the macro level topography will remain unchanged, but within each solar array, the vegetation will be disked into the top soil and then flattened with a drum roller.
>
> Under this approach, rubber-tired farming tractors towing Disking equipment will disc the top 5-7 inches of soil. A water truck will follow along the tractor to moisten the land and keep dust below acceptable levels. The tractor may make several passes to fully disc the vegetation into the top soil, preserving the underground root structure, top soil

AR060774

nutrients and seed base. A drum roller will then be used to flatten the surface and return the soil compaction to a compaction level similar to the preconstruction compaction. The intent of the roller is to compact the soil under the solar field area, simply to even out the surface after the Disking is complete.

Lastly, limited use of scrapers for micrograding will be employed to even out areas of the ground to maintain a consistent grade in each solar field area. Hydrology analysis will evaluate these areas that are susceptible to scour from storm water runoff. The ground will be graded to a level topography using micrograding only where necessary.

Vegetation would be cleared from roadways, access ways, and where concrete foundations would be used for inverter equipment, substations, and the O&M facilities. Vegetation would be cleared for construction of the drainage controls, including berms. Organic matter would be mulched and redistributed within the construction area (except in trenches and under equipment foundations). Plant root systems would be left in place, except where grading and trenching would be required for placement of solar module foundations, underground electric lines, inverter and transformer pads, road and access ways, and other facilities to provide soil stability.

To account for the above described grading approach and the other facilities and impervious surfaces discussed in the Project Site Description, the Post Project soil characteristics were adjusted as follows:

	Pre Project	Post Project	Change
1. Composite runoff index number	83.0	88.0	+5.0
2. Surface roughness coefficient “n”	0.05	0.04	-0.01

Theoretically these soil characteristic changes will result in higher runoff potential with less infiltration.

The Project terrain is relatively flat with large natural depressions scattered across the southeast portion. The natural depressions range in depth from one to five feet, and are shown on Figure 4. These depressed areas trap and hold large volumes of runoff which will help attenuate increases in peak flow and volume associated with the Project.

5.2 Results

The Pre and unmitigated Post Project hydraulic analysis results are summarized in Table 1 below. Total rainfall volume from the mountain sheds and alluvial fan shed remained constant at a total of 6,679 acre-feet.

The total rainfall volume simulated over the alluvial fan shed area resulted in infiltration, storage in the natural depressions and outflow. The unmitigated Post Project infiltration decreased by 91 acre-feet or 3.4%; storage increased by 71 acre-feet or 2.2%; and outflow increased by 20 acre-feet or 2.6%.

AR060775

The Pre and unmitigated Post Project flows have relatively shallow depths and low velocities due to the flat terrain. The maximum depth results are somewhat miss leading due to the natural depressions that are approximately five-feet deep. On average the majority of the Project site will experience flow depths less than half a foot (see Figure 5a & 5b). The unmitigated Post Project onsite flow depths increased by an average of 0.03-feet or 7.5% (see Figure 5c).

The maximum velocities occur on the fringe of the Project boundary where the mountain sheds enter the alluvial fan area. On average the majority of the Project site will experience flow velocities less than half a foot per second (see Figure 6a and 6b). The unmitigated Post Project onsite flow velocities increased by an average of 0.04 feet per second or 17.4% (see Figure 6c).

The unmitigated Post Project increases to depth, velocity and outflow are minimal as an order of magnitude to the drainage area studied. The flat terrain with natural depressions helped to attenuate the Post Project effects of decreasing the infiltration capability of the soil.

Mitigation for the Project's nominal increases can be achieved by constructing retention basins at the upstream and/or downstream edges of the Project. The retention basins should be sized with at least 20 acre-feet of combined storm water storage capacity.

TABLE 1: Hydraulic Analysis Summary

Item Description		Pre Project	Unmitigated Post Project	Post - Pre	Percent Change
Rainfall Volume					
Mountain Sheds	acre-feet	1,097	1,097	0	0.0%
Alluvial Fan Shed	acre-feet	5,582	5,582	0	0.0%
Total	acre-feet	6,679	6,679	0	0.0%
Alluvial Fan Flow Volume					
Infiltration	acre-feet	2,671	2,580	-91	-3.4%
Storage	acre-feet	3,245	3,316	71	2.2%
Outflow	acre-feet	763	783	20	2.6%
Total	acre-feet	6,679	6,679	0	0.0%
Onsite Flow Depth					
Maximum Depth	feet	5.23	5.63	0.40	7.6%
Average Depth	feet	0.40	0.43	0.03	7.5%
Onsite Flow Velocity					
Maximum Velocity	feet/sec	1.85	2.12	0.27	14.6%
Average Velocity	feet/sec	0.23	0.27	0.04	17.4%

6 SEDIMENT TRANSPORT ANALYSIS

Sediment transport occurs through the scour or deposition of soil based on storm event flow rates and soil characteristics. Hydrologic, hydraulic and soil data discussed earlier in this report were utilized for the sediment transport analysis.

6.1 Methodology

FLO-2D has a sediment transport component that can compute sediment scour or deposition for nine different methodologies. The FLO-2D user's manual identifies the Zeller and Fullerton methodology as appropriate for alluvial floodplain conditions.

Within each FLO-2D grid element, the sediment transport capacity is computed for overland flow based on the flow hydraulics. The sediment transport capacity is then compared with the sediment supply and the resulting sediment excess or deficit is uniformly distributed over the grid element.

6.2 Results

The Pre and unmitigated Post Project sediment transport analysis results are summarized in Table 2 below. On average the majority of the Pre and unmitigated Post Project site will experience sediment scour and deposition depths of plus or minus half a foot.

The unmitigated Post Project average onsite sediment scour depth (degradation) decreased by 0.07-feet or 15.9% and the deposition depth (aggradation) decreased by 0.03-feet or 5.0%. These decreases are attributable to the increase in the soil compaction which reduces the erosion potential.

The Project site experiences relatively shallow and slow flows, so the nominal increases in Post Project flow depths and velocities do not overcome the decreased erosion potential due to compaction.

TABLE 2: Sediment Transport Analysis Summary

Item Description			Pre Project	Unmitigated Post Project	Post - Pre	Percent Change
Onsite Sediment Transport						
Average Degradation Depth (-)		feet	-0.44	-0.37	0.07	-15.9%
Average Aggradation Depth (+)		feet	0.60	0.57	-0.03	-5.0%
Average Site Depth (+ or -)		feet	0.12	0.11	-0.01	-8.3%

7 PIER SCOUR ANALYSIS

As discussed earlier in this report, the solar panel pedestals will be supported by vertical steel piers. Each pier is a single W6x7.2 "I" beam. As storm water flow encounters the piers, turbulent flow will occur. The turbulent flow will cause increased local scour around the piers.

7.1 Methodology

The pier scour analysis followed the Federal Highway Administration's Hydraulic Engineering Circular No. 18 (HEC-18), "Evaluating Scour at Bridges" (4th Edition). Flow depth and velocity outputs from the FLO-2D model were used to calculate the pier scour depths at each grid element. The local scour equation and the various parameters and assumed values are as follows:

$$\frac{y_s}{a} = 2.0 K_1 K_2 K_3 K_4 \left(\frac{y}{a}\right)^{0.35} Fr^{0.43}$$

Where: y_s = Local scour depth (ft)
K_1 = 1.1 (correction factor for pier nose shape)
K_2 = 1.29 (correction factor for angle of attack of flow)
K_3 = 1.1 (correction factor for bed condition)
K_4 = 1.0 (correction factor for armoring)
a = 0.33 (pier width in feet)
y = FLO-2D average flow depth (ft);
Fr = Froude number:

$$Fr = \frac{V}{\sqrt{gy}}$$

Where: V = FLO-2D average velocity (ft/s)
g = Acceleration due to gravity (32.2 ft/s^2)

7.2 Results

The pier scour analysis results are summarized in Table 3 below. The maximum pier scour depth is 1.22-feet and the average depth is 0.39-feet (see Figure 8). The structural design and embedment depth of the solar panel pedestal piers should account for the maximum potential scour plus a factor of safety. Monitoring after large storm events should be implemented to detect piers with significant scouring.

TABLE 3: Local Pier Scour Analysis Summary

Item Description			Unmitigated Post Project
Local Pier Scour			
	Maximum Depth	feet	1.22
	Average Depth	feet	0.39

AR060778

8 CONCLUSIONS

The proposed Desert Quartzite Solar Project will cause minor impacts to the existing drainage shed area. The impacts have been minimized due to the relatively flat terrain and presence of large natural depressions that range from one to five feet deep. These large depressions store significant volumes of water which attenuate the increased runoff.

The unmitigated Post Project impacts during the 100-year storm event are as follows:

- Average Flow Depth increase of 0.03-feet
- Average Flow Velocity increase of 0.04 feet/second
- Total Outflow increase of 20 acre-feet (2.6%)

The nominal Post Project increases in flow depth, velocity and outflow can be mitigated with onsite retention basins sized with at least 20 acre-feet of combined storm water storage capacity.

The unmitigated Post Project sediment transport will be less than the pre project conditions due to soil compaction. The Project site experiences relatively shallow and slow flows, so the nominal increases in Post Project flow depths and velocities do not overcome the decreased erosion potential due to compaction.

The maximum potential pier scouring at the solar array pedestal supports is 1.22-feet. The structural design and embedment depth of the solar panel pedestal piers should account for the maximum potential scour plus a factor of safety. Monitoring after large storm events should be implemented to detect piers with significant scouring.

THIS PAGE INTENTIONALLY LEFT BLANK

EXECUTIVE SUMMARY

ES-1: INTRODUCTION

Renewable Resources Group (Applicant) proposes to construct the Blythe Mesa Solar Project (Project), a solar photovoltaic (PV) electrical generating facility of up to 485 megawatt (MW) and 8.4-mile generation interconnection (gen-tie) line that would together occupy a total of 3,660 acres. It would be located in the Palo Verde Mesa region of Riverside County—3,587 acres for the solar facility component and 73 acres for the 230 kilovolt (kV) gen-tie line. The power produced by the Project would be conveyed to the local power grid via interconnection to the Southern California Edison (SCE) Colorado River Substation, an approved new substation under construction south of Interstate 10 (I-10) and approximately five miles west of the Project site. The Project has secured a California Independent System Operator (CAISO) interconnection queue position. The Project would produce enough energy to power approximately 180,000 households and advance the goals of the California Renewable Portfolio Standard (RPS) and other similar renewable programs in the state.

In compliance with the California Environmental Quality Act (CEQA) and the National Environmental Policy Act (NEPA), Riverside County (County) and the Bureau of Land Management (BLM) have prepared this Draft Environmental Impact Report (EIR)/Environmental Assessment (EA) to inform the public about the proposed Project and to meet the need of federal, state, and local permitting agencies in considering the proposed Project. This Draft EIR/EA was further designed and intended to satisfy the requirements in the BLM's land use planning regulations applicable to the request for a right-of-way (ROW) grant to use federal lands under the Federal Land Policy and Management Act (FLPMA). The information contained in this Draft EIR/EA will be considered by the County when evaluating the Applicant's Conditional Use Permit (CUP No. 3685) and Public Use Permit (PUP No. 913), Development Agreement (DA No. 79), Change of Zone application (CZ No. 7831), establishment of an agricultural preserve and Williamson Act Contract (Agricultural Preserve Case No. 1045), and potential future cancellation of the Williamson Act Contract and Agricultural Preserve. Together, these permits and applications are collectively being considered by the County as the Project. The information in this Draft EIR/EA will also be considered by the BLM in its deliberations regarding approval of the ROW grant, and by other federal, state, and local agencies with regard to their respective permit approvals, if any.

ES-2: PROJECT OBJECTIVES/PURPOSE AND NEED

ES-2.1 County and Applicant's Project Objectives

The objectives for the Project are as follows:

- Construct a solar energy facility in order to help meet State and federal renewable energy standards and goals.
- Assist with Greenhouse Gas (GHG) reduction objectives to the maximum extent possible.
- Locate the Project facilities as near as possible to electrical transmission facilities with anticipated capacity and reserved CAISO interconnection position.
- Site the Project in an area with excellent solar energy resource, in order to maximize energy productivity from the PV panels.
- To the extent feasible, site the Project on previously disturbed land with compatible topography in a manner that minimizes environmental impacts.
- Use a proven and available solar PV technology to provide cleanly generated electricity at a competitive price for California electric ratepayers.
- Eventual decommissioning of the 485 MW solar PV electrical generating facility and associated infrastructure at the end of the energy sales contract term, if the energy buyer is not available for extension or another energy buyer does not emerge.

California has one of the most ambitious renewable energy standards in the country, and mandates have been issued to significantly increase renewable energy generation, including utility scale solar facilities like the proposed Project. In 2002, California established its Renewable Portfolio Standard (RPS) Program, with the goal of increasing the percentage of renewable energy in the state's electricity mix to 20 percent of retail sales by 2017. The state's Energy Action Plan supported this goal and required retail sellers of electricity to increase renewable energy purchases by at least one percent per year with a target of 20 percent renewables by 2010. On November 17, 2008, former Governor Arnold Schwarzenegger signed Executive Order S-14-08 requiring that "….[a]ll retail sellers of electricity shall serve 33 percent of their load with renewable energy by 2020." The following year, Executive Order S-21-09 directed the California Air Resources Board (CARB), under Assembly Bill (AB) 32 authority, to enact regulations to achieve the goal of 33 percent renewables by 2020. In recognition of the important role played by large-scale solar projects, California's Clean Energy Jobs Plan calls for the development of 8,000 MW of utility scale renewable energy projects by 2020.

California is committed to a significant and substantial increase in reliance on renewable resources for electrical power, the reduction of fossil-fuel based pollutants, and promoting the green economy, consistent with protection of the environment. Former Governor Arnold Schwarzenegger issued Executive Order S-03-05 on climate change to advance renewable energy and other solutions to lower California's GHG emissions. The California Global Warming Solutions Act of 2006 (AB 32) directed CARB to develop regulations, market mechanisms, and other actions to reduce California's GHG emissions, such as carbon dioxide, to 1990 levels by 2020.

ES-2.2 Federal Purpose and Need

In accordance with the FLPMA (Section 102(a)(7), 43 United States Code [U.S.C.] §1701(a)(7)), public lands are to be managed for multiple uses that take into account the needs of future generations for renewable and non-renewable resources. The Secretary of the Interior is authorized to grant ROWs on public lands for systems for generation, transmission, and distribution of electric energy (Section 501(a)(4), 43 U.S.C. §1761(a)(4)). The purpose and need for the proposed action is to respond, in a manner that takes into account the BLM's multiple use mandate, to a FLPMA ROW application submitted by the Applicant to construct, operate, maintain, and decommission a gen-tie line on public lands administered by the BLM, which would serve a solar energy generation facility and associated infrastructure, in compliance with FLPMA, BLM ROW regulations, other applicable federal laws and policies, and the management objectives referenced below.

The proposed action would, if approved, assist the BLM in addressing the following management objectives:

- Executive Order 13212, dated May 18, 2001, which mandates that agencies act expediently and in a manner consistent with applicable laws to increase the "production and transmission of energy in a safe and environmentally sound manner."
- Department of the Interior Secretarial Order 3285A1, dated March 11, 2009, and amended on February 22, 2010, which "establishes the development of renewable energy as a priority for the Department of the Interior."
- BLM Instruction Memorandum 2011-061, dated February 7, 2011, which prioritizes the development of solar facilities on, inter alia, "[l]ands specifically identified for solar or wind energy development in BLM land use plans; [p]reviously disturbed sites or areas adjacent to previously disturbed or developed sites; [l]ocations that minimize construction of new roads and/or transmission lines; [and l]ands adjacent to designated transmission corridors…"
- President Obama's Climate Action Plan, dated June 2013, which set a goal to double renewable electric generation by 2020. "In 2012 the President set a goal to issue permits for 10 gigawatts of renewables on public lands by the end of the year. The Department of the Interior achieved this goal ahead of schedule and the President has directed it to permit an additional 10 gigawatts by 2020."

ES-3: PUBLIC SCOPING

Consistent with CEQA and NEPA requirements, public participation and agency consultation was completed for this Project. This included meetings, and formal and informal consultation with agencies, stakeholders, landowners, and Native American Tribes. The consultation and coordination process helped to determine and focus the scope of the Draft EIR/EA and identify a range of alternatives and mitigation measures. Three sets of meetings were held for the Project: (1) CEQA Public Scoping, (2) Draft EIR/EA Informational Meetings, and (3) BLM Public Scoping.

ES-3.1 CEQA Public Scoping

In compliance with California Code of Regulations (CCR) Title 14, Section 15082(c) (CEQA Guidelines), Riverside County conducted the first public scoping meeting on December 12, 2011. The purpose was to inform the public about the Project; describe the purpose and need of the Project; provide information regarding the environmental review process; and gather public input regarding the scope and content of the Draft EIR/EA. The issues and comments that were raised by the commenters were in regard to impacts to air quality, public services and utilities, socioeconomics, hazardous materials/soils, cultural resources, and water resources.

ES-3.2 Draft EIR/EA Informational Meetings

On May 10, 2012, two informational meetings were conducted for the Project. In the morning, the BLM convened the pre-application meeting with several resource agencies who have an interest in the Project. The afternoon meeting was attended by the Project Applicant to provide Project information to Native American groups. The purpose of these meetings was to present information about Project alternatives; describe the purpose and need of the Project; provide information regarding the environmental review process; and gather input regarding the preliminary alternatives.

ES-3.3 BLM Public Scoping

On October 4, 2012, the BLM conducted a public scoping meeting in Blythe, California. The BLM and Applicant presented information about the Project, alternatives, environmental review process, and potential impacts. A question and answer session was held after the presentation. At the conclusion of the question and answer session, the open house continued and staff members were available to answer questions and gather input.

ES-4: ALTERNATIVES DEVELOPMENT

CEQA and NEPA both require consideration of a reasonable range of alternatives to the proposed Project that would feasibly attain most of the basic objectives of the Project. In addition, CEQA requires the consideration of how to avoid or substantially lessen any of the significant or adverse effects caused by the Project.

Regulation 40 CFR 1508.9(b) of the Council on Environmental Quality requires an EA to study, develop, and describe alternatives to the proposed action involving unresolved resource conflicts.

To determine which alternatives would be analyzed in this Draft EIR/EA, alternatives were evaluated as to whether they would:

1) Attain the purpose and need of the Project, as well as most of the basic objectives of the Project;
2) Have the potential to avoid or substantially lessen any of the significant or adverse effects of the Project; and
3) Be considered feasible.

ES-4.1 Alternatives Description

The following were identified as a reasonable range of alternatives to the Project that would feasibly meet the basic objectives of the Project, attain the purpose and need of the Project, but avoid or substantially lessen any of the significant or adverse effects of the Project. The Project Alternatives and the No Action Alternative are described below.

ES-4.1.1 Alternative 1: Proposed Project

The proposed up to 485 MW PV solar energy generation facility and 8.4-mile gen-tie line would occupy a total of 3,660 acres. The Project would be located on lands under the jurisdiction of the County of Riverside, the BLM, and the City of Blythe. A majority of the Project would be located within the County of Riverside and within the area governed by the County of Riverside's General Plan and the Palo Verde Valley Area Plan. The Project would likely be developed in phases that extend over several years. Pending commencement of each phase of construction, the existing agricultural lands likely would remain in agricultural production. The initial use of the Project site to be permitted under the conditional use permit will be active agricultural production. Agricultural uses are allowed uses under the entire site, but part of the site is not in an agricultural zone. To encourage agricultural use of the site to continue pending construction of solar facilities, approximately 1,249 acres would be rezoned from W-2-5 and N-A to A-1-10 (light agricultural), which would make zoning consistent throughout the solar facility site (refer to Figure 2-12 in Chapter 2). Approximately 1,485 acres, all south of I-10 and representing the land not planned to be developed immediately, would be placed into an agricultural preserve and in a Williamson Act contract (refer to Figure 2-13). As each portion of the site is developed for solar use, any Williamson Act Contract for that portion of the site and the agricultural preserve would be cancelled.

This Draft EIR/EA evaluates a construction schedule that assumes construction of the entire site within a three-year period, to ensure a conservative analysis of the most intense and concentrated construction activities reasonably possible. A longer construction duration would not result in an increase in impacts, nor would continuation of agricultural uses of the site.

A portion of the solar facility site would be within the area of the City of Blythe, within the area governed by the City's General Plan. A portion of the 230 kV gen-tie line would traverse BLM-managed lands, and that area would be governed by the California Desert Conservation Area (CDCA) Plan. The portion of the gen-tie line that would traverse BLM-managed lands that are within the area governed by the CDCA Plan, designated Multiple-Use Class M (Moderate). Within the CDCA Plan area, the proposed gen-tie lines would be located within BLM's Utility Corridor K, which is also designated as Section 368 Federal Energy Corridor 30-52 (BLM 2009). The proposed Project would produce enough energy to power approximately 180,000 households and would consist of two primary components:

- **Solar Facility Site (3,587 total acres)**
    - Solar array field that would utilize single-axis solar PV trackers (295 feet long and 140 feet wide). Six trackers with 18 north-south oriented rows of PV panels would be configured into 1.5 MW blocks (600 feet long by 470 feet wide).
    - System of interior collection power lines located between inverters and substations.
    - Up to three on-site substations (each approximately 90,000 square feet).
    - Up to two operation and maintenance (O&M) buildings (approximately 3,500 square feet each).
    - Associated communication facilities and site infrastructure.
    - Two primary off-site access roads and several interior access roads.
- **Approximately 8.4 miles of 230 kV Gen-tie Transmission Line**
    - Approximately 3.6 miles would be located within the solar facility, which would connect all on-site substations.

- Approximately 4.8 miles would extend outside of the solar facility and would be placed within a 125-foot-wide ROW and occupy 73 acres. Of this, 3.8 miles would traverse BLM-managed lands with 53 acres within the Riverside East Solar Energy Zone (SEZ).At the end of the energy sales contract term (20-year term) of Alternative 1, if the utility buyer is not available for extension or another energy buyer does not emerge, the solar arrays and gen-tie line could be decommissioned and dismantled within the Project area. Following decommissioning and dismantling of the solar facility and gen-tie line, the site would be made available for reversion to agricultural use.

ES-4.1.2 Alternative 2: No Action/Project Alternative

The No Action/Project Alternative is required by NEPA and CEQA. Under the No Action/Project Alternative, the construction of a solar generating facility and associated infrastructure would not occur. This alternative discusses existing conditions as well as what would be reasonably expected to occur in the foreseeable future if the Project was not approved and does not take place.

ES-4.1.3 Alternative 3: Northern Alternative 230 kV Gen-tie Line

Similar to Alternative 1 (proposed Project), Alternative 3 would include the interim agriculture-related actions described above, and construction, operation, and potential decommissioning of an up to 485 MW PV solar energy generation facility and associated infrastructure. It would occupy a total of 3,665 acres and would utilize the same solar array field as the proposed Project. The primary difference between Alternatives 1 and 3 is the location of the 230 kV gen-tie line that extends outside of the solar array field to the Colorado River Substation; the same 230 kV gen-tie alignment within the solar array field would be utilized for both Alternatives 1 and 3. The gen-tie alignment for Alternatives 1 and 3 would also be located within or adjacent to the same BLM utility corridor; however, Alternative 3 would be located on the north side of the Alternative 1 gen-tie alignment and within a 125-foot ROW entirely on BLM-managed lands. Like Alternative 1, the gen-tie in this alternative would be entirely within the Riverside East SEZ where it is on BLM-managed land. Under this alternative, the total length of the 230 kV gen-tie line both on-site and off-site would be 8.8 miles; 3.6 miles would be located on private lands within the array site boundary and 5.2 miles would be located off-site on BLM-managed lands. The BLM portion of the ROW would contain 78 acres. Similar to Alternative 1, at the end of the energy sales contract term of Alternative 3, if the utility buyer is not available for extension or another energy buyer does not emerge, the solar arrays and gen-tie line could be decommissioned and dismantled within the Project area. Following decommissioning and dismantling of the solar facility and gen-tie, the Alternative 3 site would be made available for reversion to agricultural use.

ES-4.1.4 Alternative 4: Southern Alternative 230 kV Gen-tie Line

Similar to Alternative 1, Alternative 4 would include the construction, operation, maintenance, and decommissioning of an up to 485 MW PV solar energy generation facility and associated infrastructure. Alternative 4 would occupy a total of 3,647 acres and would utilize the same solar array field location as the proposed Project. The primary difference between Alternatives 1 and 4 is the location of the 230 kV gen-tie line that extends from the solar array field (proposed Substation 3) to the Colorado River Substation. Alternative 4 would exit the southwestern portion of the solar array field and extend approximately four miles west to the Colorado River Substation within a 125-foot ROW. To facilitate this alignment, an additional 10,000 feet of 230 kV gen-tie line would need to be built within the solar array field extending south from the proposed Substation 3 and angling west to the site boundary. The gen-tie line would continue westerly off-site across 3.4 miles of BLM-managed lands and 0.6 mile of private lands before reaching the Colorado River Substation. Under this alternative, the total length of the 230 kV gen-tie line both on-site and off-site would be 9.5 miles; 5.5 miles would be located on private lands within the array site boundary and 4.0 miles would be located off-site. The total area of the gen-tie off-site would be about 60 acres (50 acres of BLM-managed land and 10 acres of private land). The gen-tie under this alternative would be entirely within the Riverside East SEZ where it is on BLM-managed land. Similar to Alternative 1, at the end of the energy sales contract term of Alternative 4, if the utility buyer is not

available for extension or another energy buyer does not emerge, the solar arrays and gen-tie line could be decommissioned and dismantled within the Project area. Following decommissioning and dismantling of the solar facility and gen-tie, the Alternative 4 site would be made available for reversion to agricultural use.

ES-4.1.5 Alternative 5: Reduced Acreage Alternative

Similar to Alternative 1, Alternative 5 would include the interim agriculture-related actions described above, and construction, operation, and potential decommissioning of a PV solar energy generation facility and associated infrastructure; however, Alternative 5 would eliminate development north of I-10. In comparison to the proposed Project, Alternative 5 would reduce electrical generation from a 485 MW down to a 315 MW alternating current solar PV facility located on a footprint of approximately 2,476 acres, reduced from 3,660 acres. The Reduced Acreage Alternative would include approximately 2,403 acres for the solar facility and 73 acres for the 230 kV gen-tie line. Components of the Reduced Acreage Alternative that differ from the proposed Project would include the following:

- **Solar Facility Site (2,403 total acres)**
  - Up to two on-site substations (each approximately 90,000 square feet).
  - One O&M building (approximately 3,500 square feet).
  - One primary off-site access road and several interior access roads.
- **Approximately 7.8 miles of 230 kV Gen-tie Transmission Line**
  - Approximately three miles would be located within the solar facility, which would connect all on-site substations.
  - Approximately 4.8 miles would extend outside of the solar facility and would be placed within a 125-foot-wide ROW and occupy 73 acres.

The fenced-in solar PV electric generation facility would occupy approximately 2,403 acres on privately-owned land (all within the County of Riverside). Similar to the proposed Project, the portion of the gen-tie line outside the solar facility site, from the southernmost substation to the Colorado River Substation, would traverse 3.8 miles of BLM-managed lands (approximately 58 acres) and approximately one mile of private land (approximately 15 acres). A comparison to the other alternative gen-tie alignments can be found below in ES.8.1. Similar to Alternative 1, at the end of the energy sales contract term of Alternative 5, if the utility buyer is not available for extension or another energy buyer does not emerge, the solar arrays and gen-tie line could be decommissioned and dismantled within the Project area. Following decommissioning and dismantling of the solar facility and gen-tie, the Alternative 5 site would be made available for reversion to agricultural use.

ES-5: ALTERNATIVES CONSIDERED BUT ELIMINATED

CEQA and NEPA require an Draft EIR/EA to consider a reasonable range of alternatives to the Project that would feasibly attain most of the basic objectives of the Project. In addition, CEQA requires the consideration of how to avoid or substantially lessen any adverse effects of the proposed Project. Under CEQA, the proposed Project has the potential to have significant adverse effects to aesthetics, agriculture, biological resources, cultural resources, geology and soils, hazards and hazardous materials, hydrology and water quality, paleontological resources, and traffic and transportation. With implementation of Best Management Practices (BMPs) and mitigation measures, impacts in these issue areas would be less than significant.[1]

Alternatives to the proposed Project were identified through the scoping process, informational public meetings, and preliminary studies. A number of alternatives to the proposed Project were identified. Some of these alternatives did not meet the Project objectives, purpose and need or provide the potential to avoid or minimize adverse environmental effects, or were considered infeasible through additional study and evaluation. Alternatives considered but eliminated from detailed analysis include:

- Solar Power Tower Technology
- Distributed Solar Photovoltaic Alternative
- Conservation and Energy Demand Reduction
- Alternative Site on BLM-Managed Lands
- Palo Verde Valley Floor Alternative

ES-5.1 Solar Power Tower Technology

Solar power tower technology uses a flat mirror "heliostat" system that tracks the sun and focuses solar energy on a central receiver at the top of a high tower. The focused energy is used to heat a transfer fluid (to 800 to 1,000 degrees Fahrenheit [˚F]) to produce steam and run a center power generator. The transfer fluid is super-heated before being pumped to heat exchangers that transfer the heat to boil water and run a conventional steam turbine to produce electricity. Although concentrated, solar power systems can store heated fluids to deliver electricity even when the sun is not shining. In areas of high solar insolation potential (i.e., desert environments), the land required to develop a concentrated solar energy power tower facility is comparable to that required for a PV project—approximately five acres per MW of installed capacity (NREL 2012).

ES-5.1.1 Alternative Conclusions

The use of a solar power tower technology would meet most of the basic Project Objectives; however, use of this technology would result in potentially significant glare impacts to the operations at Blythe Airport, which is located to the north and west of the proposed solar facility site's operations. Therefore, a solar power tower system alternative was not considered further.

ES-5.2 Distributed Solar Photovoltaic Alternative

There is no single accepted definition of distributed solar technology. The 2011 Integrated Energy Policy Report defines distributed generation resources as "(1) fuels and technologies accepted as renewable for purposes of the Renewables Portfolio Standard; (2) sized up to 20 MW; and (3) located within the low-voltage distribution grid or supplying power directly to a consumer." Distributed solar facilities vary in size

[1] Under NEPA, "significance" is defined in 40 CFR 1508.27, and requires federal agencies to consider the context and intensity of a proposed action and its alternatives. The BLM will determine whether this action has significant effects under NEPA using the final version of this Draft EIR/EA, following which it will either prepare a Finding of No Significant Impacts (FONSI), or initiate an Environmental Impact Statement (EIS).

from kilowatts to tens of megawatts but do not require transmission to get to the areas in which the generation is used.

A distributed solar alternative would consist of PV panels that would absorb solar radiation and convert it directly to electricity. The PV panels could be installed on residential, commercial, or industrial building rooftops or in other disturbed areas like parking lots or disturbed areas adjacent to existing structures such as substations. To create a viable alternative to the proposed Project, there would have to be sufficient newly installed panels to generate up to 485 MW of capacity. According to the 2012 CEC renewable energy acreage calculator, it would take approximately 3,464 acres to construct a 485 MW distributed solar PV alternative (0.4 MW per acre), nearly the size of the proposed Project.

ES-5.2.1 Alternative Conclusions

Although there is potential to achieve up to 485 MW of distributed solar energy, the limited number of existing facilities makes it unlikely to be feasible or present environmental benefits. The proposed Project would utilize single-axis PV trackers with high efficiency, monocrystalline, silicon solar panels. The panel design minimizes shading, and by grouping trackers close together, the technology requires 20 percent less land than conventional crystalline fixed tilt systems and 60 percent less land than thin film systems. Rooftop systems typically consist of less efficient fixed-tilt systems that may not be oriented optimally towards the sun, meaning that developers would need to obtain more surface area for the Project if constructed on a rooftop instead of on the ground. The transaction costs of obtaining multiple rooftops, the complexity of mobilizing construction crews across multiple projects including the transporting and deployment of construction materials in a less efficient manner, and the need to develop the deals to secure the same amount of PV-produced electricity can make this type of alternative infeasible.

To the extent that distributed generation projects might have fewer impacts on certain resources because they do not utilize substations and transmission facilities, this illustrates that distributed generation projects cannot meet one of the fundamental objectives of a utility-scale solar project: to provide renewable energy to utility off-takers and their customers. Rooftop systems that are not connected to the utility side of the electric grid only generate power for on-site consumption. At the same time, the difficulties in supplying a comparable amount of megawatts of clean energy to the public through the utility sector has its own set of impacts due to failure to offset the impacts of counterpart fossil fuel energy sources.

Because of the challenges associated with the implementation of a distributed solar technology, which include widely varying codes, standards, and fees; environmental requirements and permitting concerns; interconnection of distributed generation; inefficiencies; and integration of distributed generation. As a result, this technology was eliminated from detailed analysis as an alternative to the proposed Project.

ES-5.3 Conservation and Energy Demand Reduction

Conservation and demand reduction consist of a variety of approaches for the reduction of electricity use, including energy efficiency and conservation, building and appliance standards, and load management and fuel substitution.

ES-5.3.1 Alternative Conclusions

This alternative is not technically feasible as a replacement for the proposed Project, because California utilities are required to achieve aggressive energy efficiency goals. Additional energy efficiency beyond that occurring in the baseline condition may be technically possible, but it is speculative to assume that energy efficiency alone would achieve the necessary greenhouse gas reduction goals. With population growth and increasing demand for energy, conservation and demand management alone is not sufficient to address all of California's energy needs. Additionally, as stated in the California Energy Commission's 2011 Integrated Energy Policy Report, California's renewable energy goals are based on a percentage of retail sales of electricity, and reducing overall electricity demands means fewer retail sales and therefore

less renewable energy that must be generated. Furthermore, it states that conservation and demand-side management mean fewer renewable plants will need to be built. However, conservation and demand-side management would not by themselves provide the renewable energy required to meet the California renewable energy goals. Therefore, this alternative would not meet Project objectives pertaining to renewable energy goals.

ES-5.4 Alternative Site on BLM-managed Lands

Similar to the proposed Project, the Alternative Site on BLM-managed lands would involve the construction, operation, maintenance, and decommissioning of an up to 485 MW solar facility and 230 kV gen-tie line. This alternative would be located within the Developable Areas within the Riverside East (SEZ) that was identified by the BLM and Department of Energy (BLM 2012). Wilderness areas and areas of critical environmental concern (ACECs) were precluded from solar development. Additionally, the Alternative Site on BLM-managed lands would be located approximately 20 miles from the Colorado River Substation. It is also assumed that this alternative would require a BLM ROW grant and CUP approvals to allow for the construction and operation of solar facilities within BLM-managed lands.

ES-5.4.1 Alternative Conclusions

The Alternative Site on BLM-managed lands would avoid significant impacts to Agricultural Resources; however, it may not be feasible to find an Alternative Site on BLM-managed lands, because most of the land within the Developable Areas of the Riverside East SEZ is in use, proposed for other solar energy projects, or within mountainous areas. This alternative would likely have impacts similar to those of the proposed site for many resource elements, such as air quality and traffic. However, it is likely to have more severe biological, cultural, and visual resource impacts, as it would likely be located on undisturbed lands. This alternative would also be sited closer to wilderness areas and ACECs. The Alternative Site on BLM-managed lands would not present significant environmental advantages over the proposed Project.

ES-5.5 Palo Verde Valley Floor Alternative

Similar to the proposed Project, the Palo Verde Valley Floor Alternative would involve the construction, operation, maintenance, and decommissioning of an up to 485 MW solar facility and 230 kV gen-tie line. The solar facility would be situated on private lands within the Palo Verde Valley (between the Palo Verde Mesa to the west and the Colorado River to the east), instead of the Palo Verde Mesa, as well as on BLM-managed lands. It is also assumed that this alternative would require a BLM ROW grant for the 230 kV gen-tie line and CUP approvals to allow for the construction and operation of solar facilities.

ES-5.5.1 Alternative Conclusions

Similar to the proposed Project, the Palo Verde Valley Floor Alternative would also impact agricultural land. This Alternative would also be farther away from the Colorado River Substation, which would increase ground disturbance and impacts to aesthetics, air quality, biological resources, hydrology and water quality, and traffic and transportation. The proximity to the Colorado River could pose adverse impacts related to migratory birds, water resources, and the risk of flooding, which would not result from implementation of the proposed Project. As a result, this alternative was not analyzed in further detail.

ES-6: ENVIRONMENTAL IMPACTS

Impacts that would result from constructing and operating the Proposed Action and Alternatives were assessed using a methodology that documents the existing environmental conditions, then classifies and quantifies the various types of impacts that could occur. The potential impacts are compared to impact thresholds and assigned significance based on the extent of change from existing conditions. Mitigation measures are proposed as necessary to alleviate significant adverse effects. The methodology employed is discussed below.

ES-6.1 Impact Assessment Methodology

This Draft EIR/EA is a joint federal/State document prepared to comply with the requirements of both CEQA and NEPA. CEQA requires an EIR to identify the significant environmental effects of a project. An EIR presents criteria that are used to determine whether or not an adverse impact is significant under CEQA. An EIR must also describe potentially feasible mitigation measures that could minimize each significant adverse impact. Potentially feasible mitigation measures that could minimize impacts determined significant under CEQA are specifically identified in this Draft EIR/EA as "mitigation measures." This Draft EIR/EA also states whether the impact deemed significant under CEQA would remain significant after implementation of the mitigation measure(s). A CEQA significance determination is provided at the end of each resource section.

Under NEPA, "[t]he EA must describe and provide the analysis of environmental effects of the proposed action and each alternative analyzed in detail (40 [Code of Federal Regulations] CFR Part 1508.9(b)). The EA must also identify and analyze mitigation measures, if any, which will be taken to avoid or reduce potentially significant effects (see Question 39, Council on Environmental Quality [CEQ], *Forty Most Asked Questions Concerning CEQ's NEPA Regulations*, March 23, 1981)" (BLM NEPA Handbook Section 8.3.6). The analyses contained in this Draft EIR/EA provide quantitative and qualitative measures with which to review the context and intensity of the effects. These two components assist the decision-makers in determining whether to prepare an EIS or make a FONSI in instances where an EIS is not normally required or categorically exempt (40 CFR Part 1501.4(a)-(c)).

The impact assessment methodology for each resource in Chapter 4 was used to determine the significance of identified impacts, as required by CEQA. The impact locations and intensity were recorded and the impacted area described. To determine impact intensity (i.e., the severity of the potential impact), an "impact model" was developed for each resource classification using the same criteria, as applicable:

- Resource sensitivity—the probable impact(s) to a particular resource as a result of Project-related activities
- Resource quality—the pre-Project condition of the resource potentially affected
- Resource quantity—the amount of the resource potentially affected
- Duration of impact—the period of time over which the resource would be affected, measured as short-term (up to a few years) or long-term (life of the Project and beyond)
- Time of year—the season or period of time in which the resource would be affected
- Setting—consideration of the Project location, the affected region, and interests
- Expressed public concern—the amount of concern expressed by the land management agencies and the public

Pursuant to NEPA, the intent of the environmental impact analysis is to ensure that environmental information is available to public officials and the public before decisions are made and actions are taken (40 CFR Part 1500.1 [b]). In addition, the NEPA process is to be used to identify and assess reasonable alternatives to proposed actions that will avoid or minimize adverse effects of the action upon the quality of the human environment (40 CFR Part 1500.2 [e]). Environmental effects include direct, indirect, and cumulative impacts. Cumulative effects of Project implementation are discussed under each resource area.

The term *significant* as used in NEPA requires considerations of both context and intensity (40 CFR Part 1508.27). *Context* requires the BLM to analyze the significance of an action in several contexts such as society as a whole (human, national), the affected region, the affected interests, and the locality. Significance varies with the setting of the proposed action (40 CFR Part 1508.27 [a]). *Intensity* refers to the severity of effect. 40 CFR Part 1508.27(b) includes the following ten considerations for evaluating intensity:

- Impacts that may be both beneficial and adverse;
- The degree to which the proposed action affects public health or safety;

- Unique characteristics of the geographic area such as proximity to historic or cultural resources, park lands, prime farmlands, wetlands, wild and scenic rivers, or ecologically critical areas;
- The degree to which the effects on the quality of the human environment are highly uncertain or involve unique or unknown risks;
- The degree to which the action may establish a precedent for future actions with significant effects or represents a decision in principle about a future consideration;
- Whether the action is related to other actions with individually insignificant but cumulatively significant impacts;
- The degree to which the action may adversely affect districts, sites, highways, structures, or objects listed in or eligible for listing in the National Register of Historic Places or may cause loss or destruction of significant scientific cultural, or historical resources;
- The degree to which the action may adversely affect an endangered or threatened species or its habitat that has been determined critical under the Endangered Species Act of 1973;
- Whether the action threatens a violation of federal, state, or local law or requirements imposed for the protection of the environment.

To determine the severity of effect on a particular resource, the BLM must look at direct, indirect, and cumulative effects on that resource (BLM NEPA Handbook H-1790-1, Section 7.3).

An EA may be used to demonstrate that a proposed action would have effects that are significant but could be reduced or avoided through mitigation. The BLM may use a mitigated FONSI rather than an EIS if decision-makers are able to reasonably conclude, based on the EA analysis, that the mitigation measures would be effective in reducing effects to nonsignificance.

The BLM will make a determination about the significance of impacts for this Project and either initiate an EIS or issue a FONSI once the EA process is complete.

The intent of the environmental impact analysis is to provide a scientific and analytic basis for comparing the Alternatives. The analysis also identifies any adverse environmental effects that cannot be avoided should the Project be implemented, and presents mitigation measures to minimize adverse environmental impacts. Analyses for each resource area consider direct, indirect, and cumulative effects of the proposed Project and Alternatives, including short-term effects during construction and decommissioning and long-term effects during operations and maintenance.

ES-6.2 Areas of Known Controversy

Based on internal and external scoping, and input received from agencies, organizations, Native American Tribes, and members of the general public, the following environmental resources had a potential to be affected by activities related to construction, operation, maintenance, and decommissioning of the proposed Project and Alternatives and are evaluated in this Draft EIR/EA:

- Aesthetics, Visual Resources, and Reflection
- Agriculture
- Air Quality
- Biological Resources
- Cultural Resources
- Geology and Soils
- Greenhouse Gas Emissions
- Hazards and Hazardous Materials
- Hydrology and Water Quality
- Land Use and Planning
- Noise
- Paleontological Resources
- Population, Housing, Public Services, Utilities, and Socioeconomics

- Recreation
- Traffic and Transportation

Forestry and Mineral Resources are not discussed in detail in this Draft EIR/EA, because there are no forestry or mineral resources within the Project area or vicinity of the Project area.

ES-6.3 Construction, Operation, Maintenance, and Decommissioning Impacts

The implementation of the proposed Project or Alternatives has the potential to result in the following basic types of impacts to environmental resources. These impact types include the following:

Construction and decommissioning impacts associated with the short-term presence of Project construction and decommissioning activities resulting in impacts such as ground disturbance, noise, and air emissions;

Increased access-related impacts associated with enhanced accessibility by persons, such as through use of Project access roads into areas that are currently remote or inaccessible; and

Operational and maintenance related impacts associated with the long-term presence of Project facilities and improvements, such as inspections, maintenance checks, and repairs, and the long-term operation of facilities and improvements.

Construction, operation, maintenance, and decommissioning of the Project would result in a number of permanent and temporary impacts. The temporary impacts would cease upon completion of the construction phase. Many of the impacts can be minimized by implementing BMPs and specifically recommended mitigation measures.

ES-6.4 Applicable Best Management Practices

For the purposes of this Draft EIR/EA, the applicable Best Management Practices (BMPs) are: 1) requirements of existing policies, practices, and measures required by law, regulation, or local policy and 2) ongoing, regularly occurring practices. In other words, the BMPs identified in this Draft EIR/EA are inherently part of the proposed Project and Alternatives. They are not additional mitigation measures proposed as a result of the significance findings from the CEQA environmental review process. The list of BMPs may be found in Chapter 2 of this Draft EIR/EA. Applicable BMPs are referenced in each resource topic discussion of Chapter 4 of this Draft EIR/EA analysis.

ES-6.5 Mitigation Measures

Mitigation measures were examined to see if they could be effective in reducing the intensity of impacts. If analysis concluded the possibility of a potentially significant impact even after BMPs are considered, then specific mitigation was applied to lessen the impact or potentially reduce it to a less than significant level. Both 40 Code of Federal Regulations [CFR] Part 1508.20 of the Council on Environmental Quality regulations for implementing NEPA and CEQA Guidelines Section 15370 define “mitigation” as:

- Avoiding the impact altogether by not taking a certain action or parts of an action;
- Minimizing impacts by limiting the degree or magnitude of the action and its implementation;
- Rectifying the impact by repairing, rehabilitating, or restoring the affected [“impacted” under CEQA] environment;
- Reducing or eliminating the impact over time by preservation and maintenance operations during the life of the action; and
- Compensating for the impact by replacing or providing substitute resources or environments.

Mitigation is required for significant impacts under CEQA. In addition, in order to forego the preparation of an Environmental Impact Statement (EIS) under NEPA notwithstanding the potential for a project to have adverse impacts, a federal agency must find that the mitigation measures would render any environmental impact resulting from the permit activity insignificant. NEPA furthermore encourages mitigation for all of the adverse impacts of a project (40 CFR Part 1502.16(h)), and for this reason, some mitigation measures described in this document are wholly appropriate under NEPA, although the impacts they address may not be considered significant under CEQA.

Resource analysis determined **that impacts would be less than significant** with applicable BMPs to: Aesthetics, Visual Resources, and Reflection; Air Quality; Greenhouse Gases; Land Use and Planning; Recreation; and Population, Housing, Public Services, Utilities, and Socioeconomics. No additional compensatory mitigation would be required for any impacts the Project might have on these resources.

Regarding the remaining resource categories (listed below), mitigation measures are proposed for the respective resource topics in this Draft EIR/EA to avoid or reduce potentially significant impacts associated with the proposed Project. These mitigation measures can be found in Chapter 4 of this document.

- Agriculture
- Biological Resources
- Cultural Resources
- Geology and Soils
- Hazards and Hazardous Materials
- Hydrology and Water Quality
- Noise
- Paleontological Resources
- Traffic and Transportation

ES-7: MAJOR CONCLUSIONS UNDER CEQA

A discussion of the proposed Project and alternatives is included in Chapter 1 (Introduction) and Chapter 2 (Alternatives including the proposed Project) of this Draft EIR/EA. Together these chapters detail the Project objectives, the purpose and need for the Project, the proposed Project, and the identification and selection of potentially feasible alternatives, and fully address the Project's specific design. The environmental setting of the proposed Project is detailed in Chapter 3 (Affected Environment). The potential environmental effects of the proposed Project or Alternatives, implementation of BMPs, and mitigation measures to reduce or avoid these effects are described in detail in Chapter 4 along with the cumulative effects (Environmental Consequences Including Cumulative Impacts). Based on the environmental analysis conducted, it was determined that with implementation of BMPs the proposed Project and Alternatives would not result in significant impacts under CEQA to the following resources:

- Aesthetics, Visual Resources, and Reflection
- Air Quality
- Greenhouse Gas Emissions
- Land Use and Planning
- Population, Housing, Public Services, Utilities, and Socioeconomics
- Recreation

Even with implementation of BMPs some environmental resources listed below would sustain significant impacts under CEQA. However, with implementation of mitigation measures, these impacts would be reduced to less-than-significant levels under CEQA.

- Agriculture
- Biological Resources
- Cultural Resources

- Geology and Soils
- Hazards and Hazardous Materials
- Hydrology and Water Quality
- Noise
- Paleontological Resources
- Traffic and Transportation

Therefore, with implementation of BMPs and mitigation measure, the proposed Project and Alternatives would not result in significant impacts or adverse environmental effects that cannot be avoided under CEQA.

The BLM will determine whether the proposed Project and Alternatives have the potential for significant impacts using the final version of this Draft EIR/EA, after which it will either document a FONSI, or initiate an EIS.

ES-8: ALTERNATIVES COMPARISON

A comparison of the potential environmental impacts associated with the five Project Alternatives (No Project/No Action Alternative and four action Alternatives) are summarized below and in Table ES-1. The solar facility site and interior components (solar panels, substations, O&M buildings, and 34.5 kV distribution lines) are the same for each of the action Alternatives 1, 3, and 4 and would result in the same associated impacts (the solar facility site and interior components of Alternative 5 would result in fewer impacts compared to Alternatives 1,3 and 4); therefore, this discussion focuses on the impacts of the proposed gen-tie line corridor for each action Alternative.

ES-8.1 Action Alternative Resource Summary (Alternatives 1, 3, 4, and 5)

The primary difference between the proposed Project (Alternative 1) and Alternative 3 is the location of the 230 kV gen-tie line that extends outside of the solar array field to the Colorado River Substation; the same 230 kV gen-tie alignment within the solar array field would be utilized for both Alternatives 1 and 3. The gen-tie alignment for Alternatives 1 and 3 would also be located within or adjacent to the same BLM utility corridor; however, Alternative 3 would be located on the north side of the Alternative 1 gen-tie alignment and within a 125-foot ROW entirely on BLM-managed lands. As such, Alternative 3 is also referred to as the *Northern Alternative*. The primary difference between the proposed Project (Alternative 1) and Alternative 4 is the location of the 230 kV gen-tie line that extends from the solar array field (proposed Substation 3) to the Colorado River Substation. Alternative 4 would exit the southwestern portion of the solar array field and extend approximately four miles west to the Colorado River Substation within a 125-foot ROW. As such, Alternative 4 is also referred to as the *Southern Alternative*.

Among the action alternatives, the proposed gen-tie line for the Reduced Acreage Alternative (Alternative 5) is the shortest at 7.8 miles and traverses the least amount of private lands inside the solar facility (approximately 3.0 miles). Alternative 4's gen-tie line is the longest at 9.5 miles. Alternative 5 would occupy the least acreage of the action alternatives: 2,476 acres (1,184 acres less than Alternative 1; 1,189 acres less than Alternative 3; and 1,171 acres less than Alternative 4). Alternative 1, Alternative 3, and Alternative 5's gen-tie lines would parallel existing and approved transmission lines and access roads. However, approximately 3.0 miles of Alternative 4's gen-tie line would not parallel existing transmission lines or access roads and would require approximately 3.0 miles of new access roads.

As development of the solar facility under Alternative 5 would occur south of I-10, it would avoid conversion of agricultural resources to non-agricultural resources, as compared to Alternatives 1, 3, and 4. Alternative 5 would have less annual air emissions and lower impact to vegetation communities such as areas of disturbed creosote bush scrub, bajada community, irrigated alfalfa, non-irrigated wheat. The remaining direct and indirect impacts to vegetation communities under Alternative 5 would be similar to the proposed Project analyzed under Alternative 1. Alternative 1 and Alternative 5's gen-tie line would cross 22.9 acres of Desert Riparian Woodland Wash, the same as Alternative 3 but more than Alternative 4 (11.4 acres). No records or survey results indicated the presence of State- or federal-listed plants or

wildlife on Alternative 1, Alternative 3 or Alternative 5. However, based on recent survey records, the desert tortoise has a high potential to occur on the Alternative 4 gen-tie line ROW.

Action Alternatives 1, 3, and 4's solar facility site does not contain cultural resources that are eligible or assumed eligible to be listed on the National Register of Historic Places. During the cultural surveys on the alternative gen-tie lines, Alternative 1 and Alternative 5 had two unique cultural sites, Alternative 3 had five unique cultural sites, and Alternative 4 had 16 unique cultural sites. The documented unique cultural sites located on all the action Alternatives are not eligible for inclusion in either the National Register of Historic Places or the California Register of Historical Resources.

The action Alternatives would use approximately 1,354 acre-feet (AF) of water (about 451 AF per year) for construction, which would be provided by the Palo Verde Irrigation District. The Alternative 1, Alternative 3, and Alternative 5 gen-tie line corridor portions would cross one ephemeral channel; in contrast, Alternative 4 gen-tie line corridor portion would cross one ephemeral channel twice.

All the action Alternatives would promote General Plan and Area Plan and CDCA Plan policies favoring solar development. The County and City would continue to promote agricultural uses in conformity with the Agricultural Preservation Policy of the Palo Verde Valley Area Plan and the City of Blythe Open Space Guiding Policies 1 and 9, but construction of the Project and the other action Alternatives would halt agricultural use of the Project Site.

ES-8.2 No Project/ No Action Alternative (Alternative 2)

Under the No Project/ No Action Alternative, ongoing activities would continue, but new impacts associated with the implementation of the No Project/No Action Alternative are not anticipated. Relative to Alternatives 1, 3, 4, and 5, all impacts associated with the construction, operation, and maintenance of the Blythe Mesa Solar Project would be avoided. As such, there would be no effects related to GHG emissions beyond those that already occur on the Project site as a result of existing agricultural operations (zero net increase in GHG emissions). However, the beneficial impacts of the proposed Project associated with providing renewable energy in accordance with the State's adopted RPS policy would also not occur under this Alternative. That is, under the No Project/No Action Alternative, renewable energy would not be available to offset the use of energy from other sources, including fossil fuels. Consequently, the No Project/No Action Alternative would not achieve the GHG reduction associated with the proposed Project, which was estimated to range from 371,116 to 1,061,829 metric tons of carbon dioxide equivalent (CO_2e) per year.

ES-9:FEDERAL LEAD AGENCY PREFERRED ALTERNATIVE AND CEQA ENVIRONMENTALLY SUPERIOR ALTERNATIVE

CEQA requires analysis of a reasonable range of alternatives to the proposed Project to foster informed decision making and public participation (14 CCR § 15126.6(a)). The EIR shall include sufficient information about each alternative to allow meaningful evaluation, analysis, and comparison with the proposed project [or plan]. A matrix displaying the major characteristics and significant environmental effect of each alternative may be used to summarize the comparison. If an alternative would cause one or more significant effects in addition to those that would be caused by the project as proposed, the significant effects of the alternative shall be discussed, the in less detail that the significant effects of the project as proposed (*County of Inyo v. City of Los Angeles*, 124 Cal. App.3d 1). (CEQA Guidelines § 15126.6(d)).

For NEPA, EAs shall " include brief discussions … of alternatives as required by section 102(2)(E)…" (40 CFR Part 1508.9(b)). Section 102(2)(E) of the NEPA provides that agencies of the Federal Government shall "study, develop, and describe appropriate alternatives to recommended courses of action in any proposal which involves unresolved conflicts concerning alternative uses of available resources."

A comparison of the potential environmental impacts associated with the five Project Alternatives (No Project/No Action Alternative and four action Alternatives) are summarized in Table ES-1. The impacts,

mitigation measures, and residual impacts after mitigation of the proposed Project and Alternatives are detailed in Chapter 4 of this Draft EIR/EA. After comparing and weighing the benefits and impacts of all of the feasible alternatives, the BLM (NEPA Federal Agency) and the County (CEQA Lead Agency) have identified Alternative 1 (proposed Project) as the preferred/environmentally superior alternative, subject to public review.

Final identification of a preferred/ environmentally superior alternative will occur after the public review and comment period.

TABLE ES-1 ALTERNATIVES COMPARISON SUMMARY

ISSUES OR CONCERNS		ALTERNATIVE 1 PROPOSED ACTION	ALTERNATIVE 2 NO PROJECT/NO ACTION	ALTERNATIVE 3 NORTHERN ALTERNATIVE 230KV GEN-TIE LINE	ALTERNATIVE 4 SOUTHERN ALTERNATIVE 230KV GEN-TIE LINE	ALTERNATIVE 5 REDUCED ACREAGE ALTERNATIVE
Total acreage of the solar facility site	*Private*	3,587 acres	0	3,587 acres	3,587 acres	2,476 acres
Jurisdiction crossed (miles) by gen-tie line ROW	*Private (inside solar facility)*	3.6 miles	0	3.6 miles	5.5 miles (3.6 + 1.9)	3.0 miles
	Private (outside solar facility)	1.0 miles (15 acres)	0	0.0 miles	0.6 mile (9 acres)	1.0 miles (15 acres)

CHAPTER 1: INTRODUCTION

1.1 Overview

In accordance with the California Environmental Quality Act (CEQA) and the National Environmental Policy Act (NEPA), the County of Riverside (County) and the United States Department of the Interior, Bureau of Land Management (BLM) have prepared this joint Draft Environmental Impact Report/Environmental Assessment (Draft EIR/EA) for the proposed Blythe Mesa Solar Project (Project). This action is in response to the Renewable Resources Group's (Applicant) application to: (1) the County for a Conditional Use Permit and Public Use Permit; (2) the City of Blythe for a Conditional Use Permit; and (3) the BLM for a right-of-way (ROW) grant.

This Draft EIR/EA analyzes the impacts of the proposed action, a solar photovoltaic (PV) facility of up to 485 megawatts (MW) and associated infrastructure (power collection system, communication cables, overhead and underground transmission and collection lines, electrical switchyards, and operations and maintenance [O&M] buildings). The Draft EIR/EA is an informational disclosure document that:

1) informs agency decision-makers and the public of environmental impacts that are expected to result from construction, operation, maintenance, and decommissioning of the proposed Project and each agencies' respective actions;
2) presents recommended mitigation measures that, if adopted, would avoid or minimize many of the environmental impacts identified; and
3) identifies alternatives to the proposed Project that would avoid or minimize significant environmental impacts associated with the Project, and evaluates the environmental impacts associated with these alternatives.

A majority of the solar facility would occupy 3,587 acres on privately owned land under the jurisdiction of the County, approximately 334 acres of which are within the City of Blythe. The Project would be located on lands under the jurisdiction of the County of Riverside, the BLM, and the City of Blythe. A majority of the Project would be within the County of Riverside and governed by the County of Riverside's General Plan and the Palo Verde Valley Area Plan (PVVAP). A portion of the solar facility would be within the area of the City of Blythe General Plan. The County is the "lead agency" responsible for preparation of the EIR in compliance with CEQA. As the CEQA lead agency, the County is responsible for conducting the CEQA review and has final approval of the Project. The County is responsible for coordinating with the Applicant, public, and associated agencies during the CEQA process. When more than one agency is involved in a project, the agency with primary responsibility for approving a project is the lead agency for purposes of following the CEQA protocol. Other agencies with discretionary approval power over the project are called "responsible agencies." The City of Blythe is a responsible agency that has actively participated in the NEPA/CEQA process and review of this Draft EIR/EA.

A portion of the 230 kilovolt (kV) generation interconnection (gen-tie) line would traverse BLM-managed lands. The BLM is the lead federal agency responsible for preparation of the EA in compliance with NEPA. The information contained within this Draft EIR/EA will be considered by all applicable decision-makers in determining whether to grant the approvals the Applicant requests.

1.1.1 Project Overview

The proposed Project encompasses 3,660 acres and consists of two primary components:

- **Solar facility site (3,587 total acres)**
    - Solar array field that would utilize single-axis solar PV trackers (295 feet long and 140 feet wide). Six trackers with 18 north-south oriented rows of PV panels would be configured into 1.5 MW blocks (600 feet long by 470 feet wide).
    - System of interior collection power lines located between inverters and substations.

- Up to three on-site substations (each approximately 90,000 square feet).
- Up to two O&M buildings (approximately 3,500 square feet each).
- Associated communication facilities and site infrastructure.
- Two primary off-site access roads and several interior access roads.

- **Approximately 8.4 miles of 230 kV gen-tie transmission line**

    - Approximately 3.6 miles would be located within the solar facility, which would connect all on-site substations.
    - Approximately 4.8 miles would extend outside of the solar facility and would be placed within a 125-foot-wide ROW and occupy 73 acres. Of this, 3.8 miles would traverse BLM-managed lands with 53 acres within the Riverside East Solar Energy Zone (SEZ). At the end of the energy sales contract term (20-year term) of Alternative 1, if the utility buyer is not available for extension or another energy buyer does not emerge, the solar arrays and gen-tie line could be decommissioned and dismantled within the Project area. Following decommissioning and dismantling of the solar facility and gen-tie line, the site would be made available for reversion to agricultural use.

The fenced-in solar PV electric generation facility would occupy approximately 3,587 acres on privately owned land (approximately 3,253 acres are within the County of Riverside and approximately 334 acres are within the City of Blythe). The portion of the gen-tie line outside the solar facility site, from the southernmost substation to the Colorado River Substation, would traverse 3.8 miles of BLM-managed lands (approximately 58 acres) and approximately one mile of private land (approximately 15 acres). Figure 1-1, illustrates the solar facility site, gen-tie line location, and jurisdictions within the Project vicinity. The term "Project area" is used in this document to refer to the proposed 485 MW solar PV facility and associated infrastructure (3,587 acres), as well as the proposed 230 kV transmission line (gen-tie line) corridor (73 acres). The proposed solar facility would be considered a non-federal connected action because the solar facility must interconnect to the electrical grid via a gen-tie line; without a gen-tie line on BLM-managed land the solar facility site would be stranded.

Two alternative gen-tie line corridors are considered in this Draft EIR/EA—the Northern Alternative (Alternative 3) and Southern Alternative (Alternative 4). The proposed solar facility site would be the same for Alternatives 3 and 4; however, the main difference between the Alternatives is the location of the 230 kV gen-tie line corridor that extends outside the solar facility site. The Northern Alternative gen-tie line corridor would occupy 95 acres and the Southern Alternative gen-tie line corridor would occupy 60 acres. The Reduced Acreage Alternative's (Alternative 5) solar facility site would be within the boundary of the proposed Project; however, it would occupy a smaller footprint than the proposed Project. The solar facility development for Alternative 5 would occur south of Interstate 10 (I-10). Refer to Chapter 2 (*Alternatives Including the Proposed Project*) for a detailed description of the proposed Project, Alternatives, and regulatory permits needed for construction and implementation.

The initial use of the Project site to be permitted under the conditional use permit will be active agricultural production. To encourage agricultural uses to continue on the site until solar facility development occurs, approximately 1,249 acres of the solar facility site would be rezoned to an agricultural zone (refer to Figure 2-12 in Chapter 2). Approximately 1,485 acres would be placed in an agricultural preserve and potentially placed in a Williamson Act Contract (refer to Figure 2-13 in Chapter 2). The solar facilities in the areas subject to these Williamson Act protections would be constructed later, in accordance with market demand and public interest, and such development would necessitate cancellation of the applicable Williamson Act Contract and preserve.

1.1.2 Project Location

The proposed Project is located in east Riverside County, approximately five miles west of central Blythe and 40 miles east of Desert Center (refer to Figure 1-1); more specifically, the proposed Project is located north and south of I-10, west of Neighbors Boulevard and Arrowhead Boulevard, and south and east of the Blythe Airport.

1.1.3 Regional Setting

The proposed Project is located in the Palo Verde Valley along the western edge of the City of Blythe, near the Colorado River. The Project area is situated on Palo Verde Mesa and is part of the Colorado Desert. The topography of the site is relatively flat, sloping toward the southeast, and elevations range from 260 to 400 feet above mean sea level. An ephemeral stream bisects the solar facility site and the transmission line would traverse an ephemeral stream. The Project area is generally bounded by the Big Maria Mountains on the northwest, the McCoy Mountains on the west, the Mule Mountains on the southwest, and the Colorado River on the east. These mountain ranges, trending northwest to southeast, create a natural barrier between the Colorado River and the greater Colorado Desert. Urban development near and adjacent to the Project area consists of agricultural fields and groves, residences, the Blythe Airport, the Blythe Generating Plant, electrical transmission lines, and commercial businesses. The Project area also includes undeveloped open desert that is managed by the BLM and illustrated by the yellow shaded areas in Figure 1-2.

The subtropical climate of the Colorado Desert is characterized by dry, mild winters averaging 45 degrees Fahrenheit (°F) and dry, hot summers averaging 104°F. Summer highs have been known to reach 120°F. Precipitation ranges between two and ten inches per year, mostly occurring between November and March. Although rainfall is primarily in the winter months, the region is periodically influenced by tropical weather conditions including sudden monsoonal summer storms.

1.1.4 Local Setting and Surrounding Land Uses

The Project area is primarily characterized by both active and previously farmed agricultural land uses. Active agricultural uses include a citrus grove and wheat and alfalfa fields. Jojoba was previously grown for commercial purposes. Existing vacant land consists of either fallow farmland or creosote bush scrub.

The Project area is situated on the urban fringe of the City of Blythe. Urban development near and adjacent to the Project area includes the community of Nicholls Warm Springs/Mesa Verde, Blythe Airport, the 520-MW natural gas-fired Blythe Generating Plant, an existing solar facility site (Blythe Solar Project, owned by NRG), electrical substations, electrical transmission lines, ancillary agricultural facilities, dirt roads, and commercial businesses. I-10 crosses through the study area in an east-west alignment. Refer to Figure 1-1.

The solar facility site includes the assessor's parcel numbers listed in Table 1-1. The parcels that would be traversed by the proposed and Alternative gen-tie lines are listed in Table 1-2.

1.1.5 Zoning

The Project would be located on lands under the jurisdiction of the County of Riverside, the BLM, and the City of Blythe. A majority of the Project would be located within the County of Riverside and within the area governed by the County of Riverside's General Plan and the Palo Verde Valley Area Plan. A portion of the solar facility site would be within the area of the City of Blythe, within the area governed by the City's General Plan. A portion of the 230 kV gen-tie line would traverse BLM-managed lands, and that area would be governed by the California Desert Conservation Area (CDCA) Plan.

Figure 1-3 illustrates the zoning for the County of Riverside and City of Blythe. Portions of the Project located within area governed by the Palo Verde Valley Area Plan are currently zoned as follows:

- Controlled Development Areas (W-2-10) (10-acre minimum)
- Controlled Development Areas (W-2-5)
- Light Agriculture (A-1-10)
- Heavy Agriculture (A-2-10)

Zoning designations adjacent to and surrounding the Project area within the Palo Verde Valley Area Plan area consist of the following:

- Rural Residential (R-R)
- Light Agriculture (A-1-2 1/2 and A-1-10)
- Controlled Development Areas (W-2-10 and W-2-2 1/2)
- Residential Agricultural (R-A-5)
- Manufacturing-Service Commercial (M-SC)
- Controlled Development with Mobile Homes (W-2-M)
- Tourist Commercial (C-T)
- Scenic Highway Commercial (C-P-S)
- Industrial Park (I-P)
- Manufacturing-Heavy (M-H)
- Mobile Home Subdivision-Rural (R-T-R)
- Heavy Agriculture (A-2-10 and A-2-2 1/2)
- Not Applicable (N-A)

Portions of the Project located within the City of Blythe are currently zoned:

- Agriculture (A)
- Service Industrial (I-S)

The adjacent and surrounding City of Blythe zoning consists of the following:

- Agriculture (A)
- Rural Residential (R-R)
- General Commercial (C-G)
- General Industrial (I-G)

1.1.6 BLM Land Use Plan Conformance

Figure 1-4 illustrates the portion of the gen-tie line for the proposed action (and alternatives) that would traverse BLM-managed lands. These lands are within the area governed by the CDCA Plan, as amended and within the Riverside East Solar Energy Zone (SEZ). The Riverside East SEZ was designated through the Approved Resource Management Plan Amendments/Record of Decision for Solar Energy Development in Six Southwestern States (Western Solar Plan) (BLM 2012a). A SEZ is defined by the BLM as “an area within which the BLM will prioritize and facilitate utility-scale production of solar energy and associated transmission infrastructure development” (BLM 2012b).

The CDCA Plan requires that sites associated with power generation or transmission not identified in the Plan or outside of transmission corridors be considered through the plan amendment process. The Western Solar Plan amended the CDCA Plan to “identify all SEZ lands within the CDCA as sites associated with power generation or transmission” (BLM 2012b). Because the Western Solar Plan has satisfied the requirement of the CDCA Plan for a plan amendment, any ROW issued by BLM for the proposed action (or alternatives) would be in conformance with the CDCA Plan, as amended.

1.2 Purpose and Need/Project Objectives

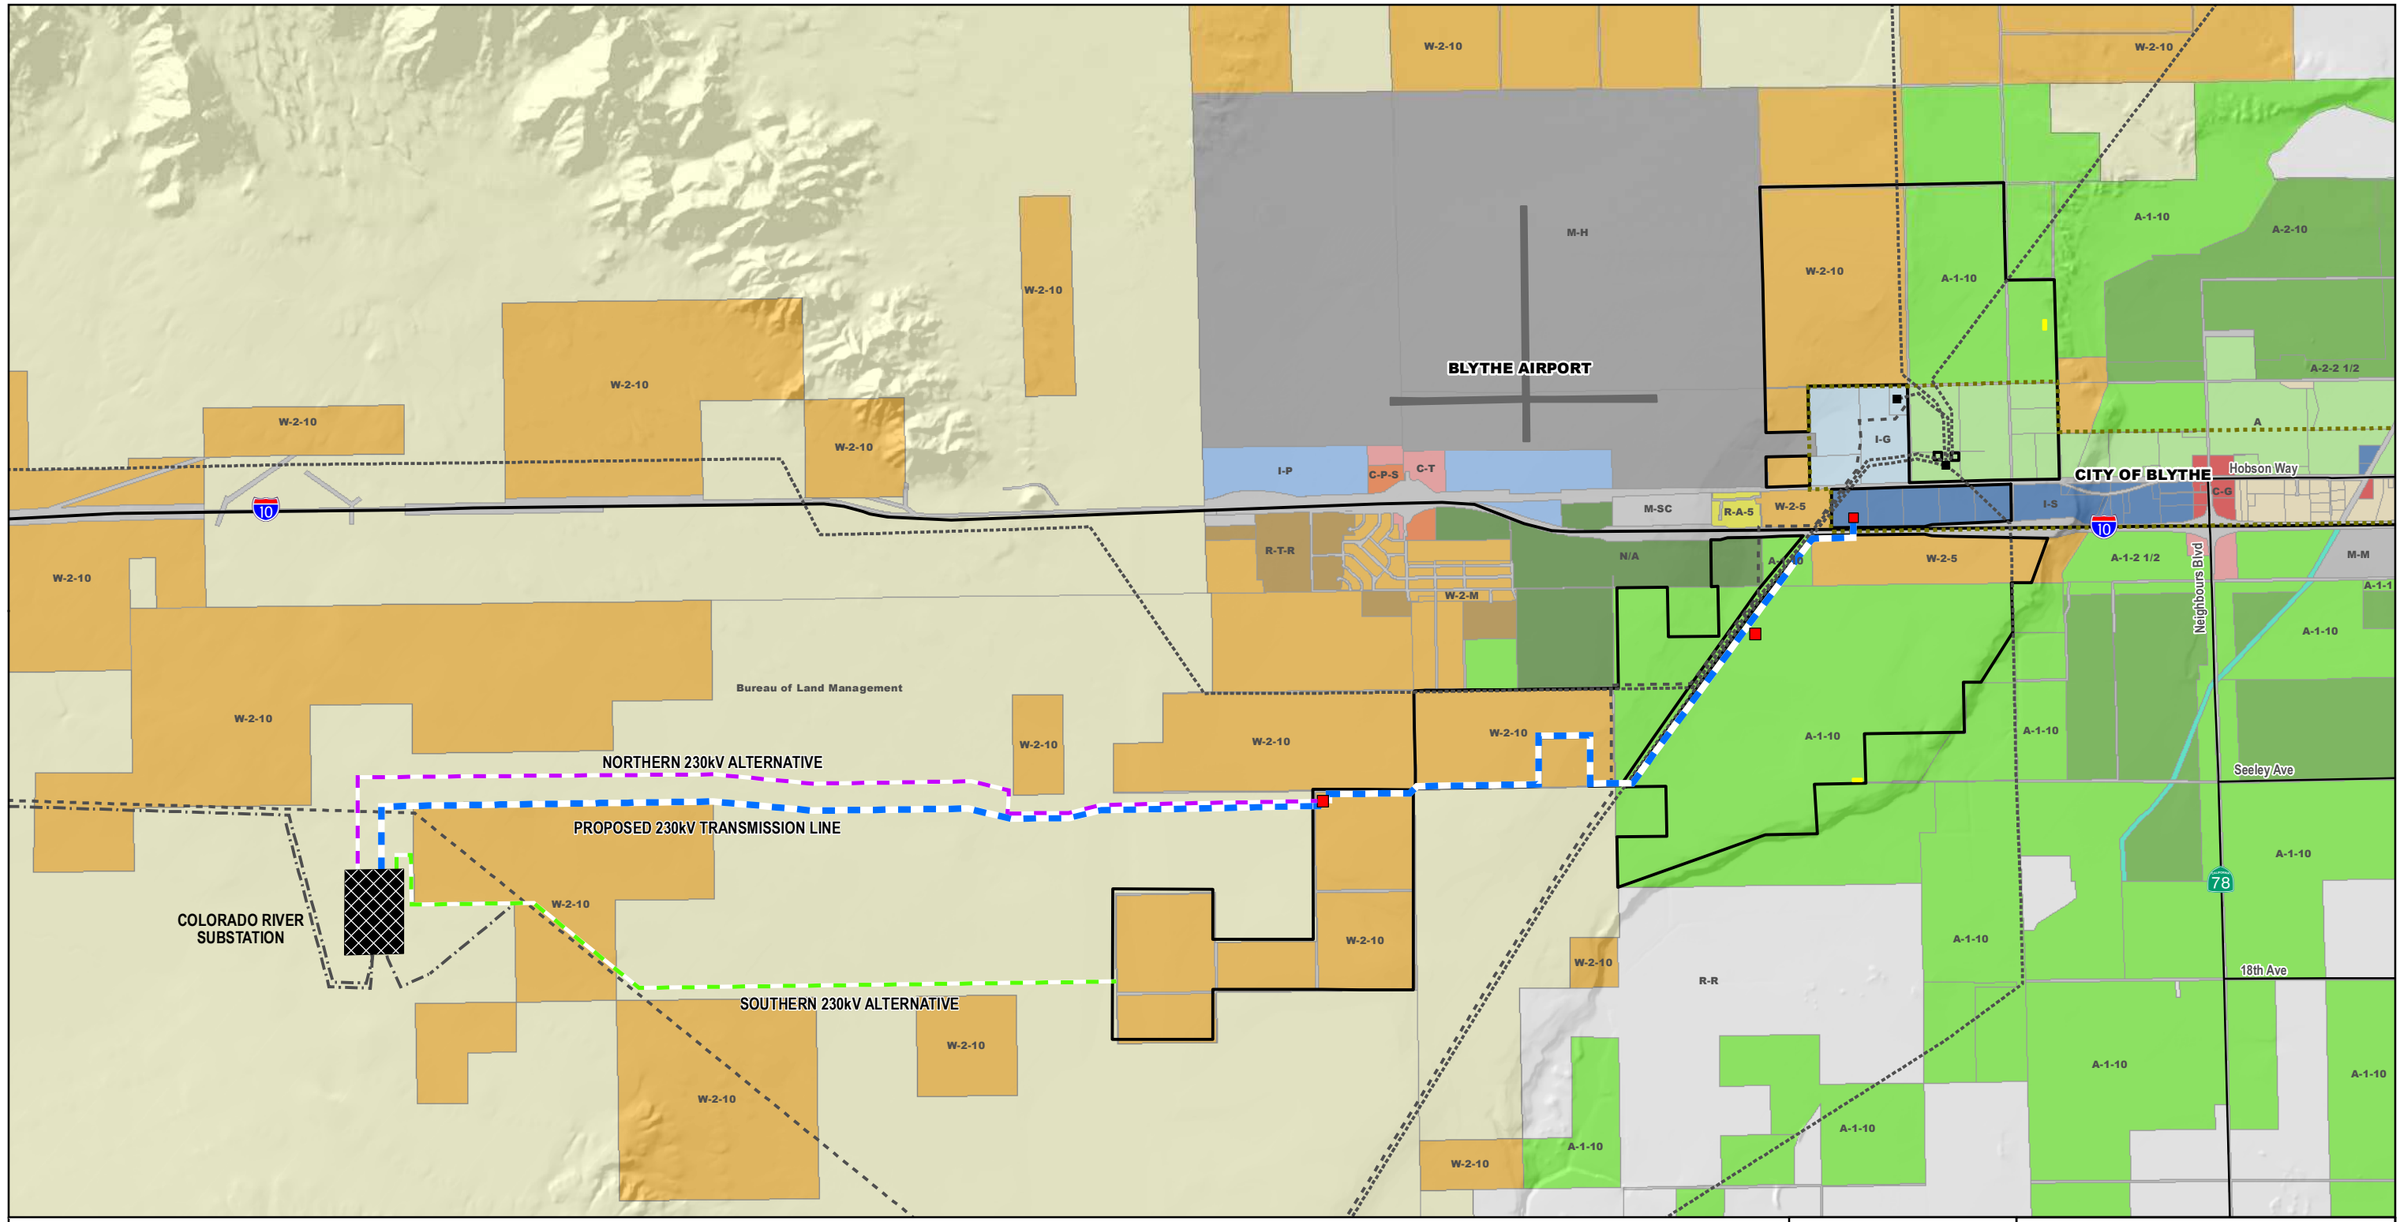
1.2.1 Federal Purpose and Need

In accordance with the Federal Land Policy and Management Act (FLPMA) (Section 103(c), 43 United States Code [U.S.C.] §1702(c)), public lands are to be managed for multiple uses that take into account the needs of future generations for renewable and non-renewable resources. The Secretary of the Interior is authorized to grant ROWs on public lands for systems for generation, transmission, and distribution of

electric energy (Section 501(a)(4), 43 U.S.C. §1761(a)(4)). The purpose and need for the proposed action is to respond, in a manner that takes into account BLM's multiple use mandate, to a FLPMA ROW application submitted by the Applicant to construct, operate, maintain, and decommission a gen-tie line on public lands administered by the BLM, which would serve a solar energy generation facility and associated infrastructure, in compliance with FLPMA, BLM ROW regulations, other applicable federal laws and policies, and the management objectives referenced below.

The proposed action would, if approved, assist the BLM in addressing the following management objectives:

- Executive Order 13212, dated May 18, 2001, which mandates that agencies act expediently and in a manner consistent with applicable laws to increase the "production and transmission of energy in a safe and environmentally sound manner."
- Department of the Interior Secretarial Order 3285A1, dated March 11, 2009 and amended on February 22, 2010, which "establishes the development of renewable energy as a priority for the Department of the Interior."
- BLM Instruction Memorandum (IM) 2011-061, dated February 7, 2011, which prioritizes the development of solar facilities on, inter alia, "[l]ands specifically identified for solar or wind energy development in BLM land use plans; [p]reviously disturbed sites or areas adjacent to previously disturbed or developed sites; [l]ocations that minimize construction of new roads and/or transmission lines; [and l]ands adjacent to designated transmission corridors…"
- President Obama's Climate Action Plan, dated June 2013, which set a goal to double renewable electric generation by 2020. "In 2012 the President set a goal to issue permits for 10 gigawatts of renewables on public lands by the end of the year. The Department of the Interior achieved this goal ahead of schedule and the President has directed it to permit an additional 10 gigawatts by 2020."



For NEPA purposes, the purpose and need statement must describe the BLM's purpose and need for action, not the applicant's interests and objectives (BLM NEPA Handbook (H-1790-1), Section 6.2). The applicant's interests and objectives, including any constraints or flexibility with respect to their proposal, help inform the BLM's decision and cannot be ignored in the NEPA process (BLM IM 2011-059).

Decisions to be Made by BLM

The BLM will decide whether to deny the proposed ROW, grant the ROW, or grant the ROW with modifications. The BLM may include any terms, conditions, and stipulations it determines to be in the public interest, which may include modifying the proposed use or changing the route or location of the proposed facilities (43 CFR Part 2805.10(a)(1)). The decisions to be made by the BLM will not require a land use plan amendment because such an amendment has previously occurred upon the Department's issuance of the Western Solar Plan in October 2012 (see section 1.1.6).

1.2.2 Decisions to be Made by County of Riverside

This Draft EIR/EA will be used by the County, in conjunction with other information developed in the County's formal administrative record for the Project, when considering whether to approve the Conditional Use Permit (CUP) and Public Use Permit (PUP) for the construction, operation, maintenance, and decommissioning of the proposed Project on lands subject to County jurisdiction. Pursuant to CEQA requirements, the County will determine the adequacy of the Final EIR and, if determined adequate, will certify the document as complying with CEQA.

The Energy Production and Utility Corridors Element of the CDCA Plan (1998) indicates that the width of joint use corridors may vary from two to five miles (these two distance standards describe the width of the planning corridor). Although BLM's GIS data reflect only a two-mile wide corridor standard for Corridor K (shown in dark blue), the CDCA Plan itself (pages 93-94) provides for a five-mile wide corridor standard "where there are so many facilities and merging corridors that a five-mile width is needed to ensure sufficient space for system integrity and flexibility." This figure shows the five-mile wide corridor extending three miles south of the dark blue area to avoid BLM lands classified for "Limited Use," the FAA Navigation Tower, and restricted land uses near the Blythe Airport.

POWER ENGINEERS RENEWABLE RESOURCES GROUP

THIS PAGE INTENTIONALLY LEFT BLANK

1.2.3 County and Applicant's Project Objectives

The County and Project Applicant have set forth the following objectives for the proposed Project:

- Construct a solar energy facility in order to help meet State and federal renewable energy standards and goals.
- Assist with greenhouse gas (GHG) reduction objectives to the maximum extent possible.
- Locate the Project facilities as near as possible to electrical transmission facilities with anticipated capacity and reserved California Independent System Operator interconnection position.
- Site the Project in an area with excellent solar energy resource, in order to maximize energy productivity from the PV panels.
- To the extent feasible, site the Project on previously disturbed land with compatible topography in a manner that minimizes environmental impacts.
- Use a proven and available solar PV technology to provide cleanly generated electricity at a competitive price for California electric ratepayers.
- Eventual decommissioning of the 485 MW solar PV electrical generating facility and associated infrastructure at the end of the energy sales contract term, if the energy buyer is not available for extension or another energy buyer does not emerge.

California's Renewable Energy Standards and Goals

California's Renewable Portfolio Standard (RPS) required California's investor-owned electric utilities to obtain 20 percent of the electricity that they supply from renewable sources by 2010. Executive Order S-14-08 mandated that "all retail sellers of electricity shall serve 33 percent of their load with renewable energy by 2020." State government agencies have been directed to take all appropriate actions to implement this target in all regulatory proceedings, including siting, permitting, and procurement for renewable energy power plants and transmission lines. California's three large investor-owned utilities (Pacific Gas and Electric, San Diego Gas and Electric, and Southern California Edison) collectively served 19.6 percent of their 2012 retail electricity sales with renewable power (CPUC 2013).

California policy has mandated significant increases in renewable energy generation, including utility scale solar facilities like the proposed Project, and requires that California utilities meet their electrical supply needs from both large central station power sources, and from distributed generation. "Utility scale power plants can take advantage of economies of scale early in the growth of new technologies. In recognition of the important role played by large-scale solar projects, California's Clean Energy Jobs Plan calls for the development of 8,000 megawatts of utility scale renewable energy projects by 2020" (http://www.jerrybrown.org/sites/default/files/6-15%20Clean_Energy%20Plan.pdf).

Greenhouse Gas Reduction

California is committed to a significant and substantial increase in reliance on renewable resources for electrical power, the reduction of fossil-fuel based pollutants, and promoting the green economy, consistent with protection of the environment. The RPS embodies this commitment, but it is evident in other statutes and policies as well, in particular those policies that aim to reduce California's contribution of approximately 6.2 percent of the total United States GHG.

Former Governor Arnold Schwarzenegger issued Executive Order S-03-05 on climate change to advance renewable energy and other solutions to lower California's GHG emissions. Further, in enacting the California Global Warming Solutions Act of 2006 (Assembly Bill 32), the Legislature found that global warming poses a serious threat to California's economic well-being, public health, natural resources, and environment. Aspiring to exercise a global leadership role, Assembly Bill 32 directed the California Air Resources Board (CARB) to develop regulations, market mechanisms, and other actions to reduce California's greenhouse gas emissions, such as carbon dioxide, to 1990 levels by 2020 (see Health and Safety Code, § 38501).

In fulfilling its duties under Assembly Bill 32, CARB determined that electricity generation accounts for approximately 22 percent of carbon dioxide (CO_2) emissions in California due to the burning of fossil fuel energy sources such as coal and natural gas. Renewable energy power plants are urgently needed to address the emissions and enable the State to meet its GHG reduction objectives and RPS standard. The Project is anticipated to produce approximately 1,410,000,000 kilowatt hours (kWh) of electrical energy per year with corresponding operational GHG emissions of approximately 271 metric tons of CO_2 equivalent (CO_2e), or 806 metric tons of CO_2e if the amortized construction and operational emissions are added (refer to the Air Quality Technical Report). In comparison, gas turbine and coal-fired power plants of the same electrical energy output are estimated to produce approximately 371,922 and 1,062,635 metric tons of CO_2e, respectively. The net GHG emission displacement or offset of the Project's solar facility in place of a conventional fossil-fuel combustion power plant is estimated to range from 371,116 to 1,061,829 CO_2e per year.

Proximity to Electrical Transmission Facilities

A major impediment to meeting the RPS is transmission line capacity and availability. California Independent System Operator (CAISO) manages the high-voltage transmission system and controls the process of obtaining rights to interconnect to the statewide grid. To obtain permission to interconnect with transmission facilities, an electric generator must submit an interconnection application to CAISO, which then places the electric generator into the "interconnection queue" and evaluates and apportions the cost of any associated transmission facility upgrades. Accordingly, a key driver in achieving the State's RPS is to locate renewable energy power plants where transmission capacity is expected to be available and sufficient queue position has been reserved by the electric generator, such that interconnection approvals can be granted within the near term.

The Project would be located within five miles of Southern California Edison's Colorado River Substation, a component of the Devers-Palo Verde 2 Transmission Line project, which received its approval from the California Public Utilities Commission (CPUC) in July 2011 (Decision D.11-07-011) and is under construction. The portion of the proposed 230 kV gen-tie line that is outside of the solar facility would also be collocated in a utility corridor with three approved transmission lines (Blythe Solar Power Project 220 kV gen-tie line, Devers-Palo Verde 2 500 kV Transmission Line, and McCoy Solar Energy Project 230 kV gen-tie line). A portion of the proposed gen-tie line within the solar facility would be collocated within the existing Western Area Power Administration's 161 kV transmission line and existing Blythe 230 kV transmission line.

High Potential Solar Resource Area

The Blythe area receives anywhere between 6.0 and 7.0 kilowatt hours per square meter per day ($kWh/m^2/day$) of solar radiation energy, giving it a higher degree of solar radiation than most areas within the United States (NREL 2012). The BLM and Department of Energy prepared a Solar Energy Development Programmatic Environmental Impact Statement identified the Riverside East study area (of which Blythe is a part) as having a high potential for solar resources (BLM and DOE 2012). Also, there are a number of proposed and approved solar projects that may be constructed in close proximity to the Blythe area (refer to the Cumulative Project Map found in Chapter 3, Section 3.3). As such, the Project would be sited in an area with excellent solar energy resources in order to maximize productivity from the PV panels.

Site the Project on Disturbed Land and Minimize Adverse Environmental Impacts

To minimize adverse environmental impacts, such as impacts to biological, cultural, and water resources, the solar Project would be sited on land with flat topography that has been previously disturbed by ongoing agricultural activities. It would also be adjacent to the 520 MW natural gas-fired Blythe Generating Plant and would be located one mile east of the Blythe Airport. The solar facility site is bisected by I-10 and has two existing 161 kV transmission lines traversing the site.

Proven and Available Solar PV Technology

The Project would use proven and available ground mounted, tracked, solar PV technology that provides efficient solar energy at a cost-effective utility scale. Solar PV technology has been commercially used for over 40 years. According to the U.S. Solar Market Insight Report, in 2011, 1,855 MW of photovoltaic solar systems were installed in the United States and the cumulative PV capacity operating in the County now stands at 3,954 MW (Solar Energy Industries Association 2011).

1.3 Joint CEQA/NEPA Document

This Draft EIR/EA was prepared as a joint state/federal environmental document (State Clearinghouse Number 2011111056 and EA Number 0021). This document analyzes the effects of the proposed Project (solar facility site and gen-tie line corridor) and Alternatives.

1.3.1 CEQA Environmental Impact Report

Under CEQA, as amended (Public Resources Code Section 21080(a)), an environmental review document must be prepared, reviewed, and certified by the decision-making body before action is taken on any non-exempt discretionary project proposed to be carried out or approved by a State or local public agency in California. This EIR serves as the environmental review document that evaluates the potential environmental effects associated with implementation of the proposed Project. The County is the lead agency responsible for preparation of this EIR in compliance with CEQA. This EIR has been prepared pursuant to CEQA (California Public Resources Code Section 21000 et seq.) and the CEQA Guidelines (California Code of Regulations, Title 14, Section 15000 et seq.).

The EIR will serve as an informational disclosure document for the County, responsible agencies, and other interested parties. The County will consider the conclusions of the Final EIR, in light of the entire administrative record, before certifying the Final EIR and taking action on the Project. The following are included among the stated purposes of an EIR in the CEQA Guidelines:

- Disclose significant environmental impacts that are expected to result from the construction, operation, and maintenance of the proposed Project;
- Indicate ways in which significant impacts can be avoided or mitigated;
- Identify any unavoidable adverse impacts that cannot be mitigated; and
- Identify feasible alternatives to the Project that would substantially lessen or eliminate significant adverse impacts.

1.3.2 NEPA Environmental Assessment

NEPA requires the preparation of an Environmental Impact Statement (EIS) for all “major Federal actions significantly affecting the quality of the human environment” 42 U.S.C. §4332(2)(C). Where, as here, an agency's regulations do not plainly require the preparation of an EIS for a particular type of project, however, the agency must first prepare an EA to determine whether the action will have a significant effect on the environment and whether an EIS must consequently be prepared. See 40 CFR Part 1501.4. If the agency’s analysis determines that the action, with or without mitigation measures, will not have a significant effect on the environment, then the agency may issue a Finding of No Significant Impact (FONSI) in lieu of preparing an EIS (40 CFR Parts 1501.4 and 1508.9). The FONSI must be accompanied by ‘a convincing statement of reasons’ to explain why a project’s impacts are insignificant.” *Blue Mountains Biodiversity Project*, 161 F.3d 1208, 1212 (9th Cir. 1998), *cert den.*, 1999 U.S. LEXIS 4045 (1999).

Identifying a significant effect on the environment involves consideration of the context and intensity of the proposed action. Agencies consider context (whether it be “society as a whole (human, national), the affected region, the affected interests, [or] the [affected] locality”) because “[s]ignificance varies with the setting of the proposed action.” 40 CFR Part 1508.27(a). To evaluate intensity, agencies consider the

degree to which the effects of the action are highly uncertain, affect public health or safety, are likely to be highly controversial, or involve unique or unknown risks. Whether the geographic area of the action has "unique characteristics," such as "proximity to historic or cultural resources, park lands, prime farmlands, wetlands . . . or ecologically critical areas," whether the Project "may cause loss or destruction of significant scientific, cultural, or historic resources," and the likelihood of cumulative impacts are additionally relevant. Finally, agencies must consider whether the decisions made in an EA might "establish a precedent for future actions with significant effects" 40 CFR Part 1508.27(b)(1)-(10).

Notwithstanding the fact that an EA is intended to be a concise document (40 CFR Part 1508.9), courts have allowed agencies to consider the effect of mitigation measures in determining whether preparation of an EIS is necessary. *Preservation Coalition, Inc. v. Pierce*, 667 F.2d 851, 860 (9th Cir. 1982). A mitigated EA can consequently be rather lengthy, especially when combined with the requirements of an EIR. An agency decides whether or not an EIS is warranted based on the aforementioned factors and whether significant measures are undertaken as needed to mitigate the effects of the action below levels of significance – not the length of the analysis.

The gen-tie line for the proposed solar facility would traverse BLM-managed lands and trigger the need for environmental review with BLM as the NEPA lead agency. In accordance with NEPA (42 U.S.C. § 4321 et seq.); CEQ's NEPA regulations (40 CFR Parts 1500-1508); the Department of the Interior's NEPA regulations, 43 CFR Part 46; the BLM NEPA Handbook, H-1790-1; FLPMA Sections 201, 202, and 206, (43 U.S.C. §§ 1711, 1712, 1716; 43 CFR Part 1600); and the BLM Land Use Planning Handbook, H-1601-1, this joint Draft EIR/EA (1) describes the affected environment relevant to potential impacts of the proposed action, action alternatives, and no action alternative; (2) evaluates the environmental impacts that are expected to result from construction, operation, maintenance, and decommissioning of the proposed gen-tie line and its alternatives in the BLM ROW; (3) evaluates the indirect impacts of a non-federal connected action (the proposed solar facility); and (4) identifies and characterizes cumulative impacts that could result from the proposed action (and its action alternatives) in relation to other ongoing or reasonably foreseeable activities within the surrounding area. Additionally, this Draft EIR/EA presents recommended mitigation measures that, if adopted, would avoid, minimize, or mitigate the direct and indirect environmental impacts identified. The information contained in this Draft EIR/EA will be considered by the BLM in its deliberations regarding approval of the ROW grant, and may also be considered by other federal agencies for use in decision-making to protect, preserve, and enhance the human environment and natural ecosystems.

As previously described, the solar facility must interconnect to the electrical grid via a gen-tie line; without a gen-tie line on BLM-managed lands, the solar facility site would be stranded. There is no private land alternative for a gen-tie line to connect the solar facility to the Colorado River Substation. The solar facility is a non-Federal connected action. Connected actions are those actions that are "closely related" and "should be discussed" in the same NEPA document (40 CFR Part 1508.25(a)(1)). Actions are connected if they automatically trigger other actions that may require an EIS; cannot or will not proceed unless other actions are taken previously or simultaneously; or are interdependent parts of a larger action and depend on the larger action for their justification (40 CFR Part 1508.25(a)(i, ii, iii). If a non-federal connected action and its effects can be prevented by BLM decision-making, then the effects of the non-federal action are properly considered indirect effects of the BLM action and must be analyzed as effects of the BLM action (40 CFR Parts 1508.7 and 1508.25). Because it can be difficult to distinguish between direct and indirect effects, BLM policy does not require NEPA documents to differentiate between the terms (BLM NEPA Handbook (H-1790-1), Section 6.8.2 (2008)). This EA analyzes the direct, indirect, and cumulative effects of the entire Project.

1.4 Draft EIR/EA Format and Content

1.4.1 Volumes I and II

This is a joint Draft EIR/EA document in compliance with both CEQA and NEPA. The document is longer and more complex than would be typical if the document were an EIR or EA only.

The CEQA Guidelines provide that each EIR contain essential elements of discussion. Table 1-3 identifies each CEQA element that must be described in an EIR along with a reference to the corresponding section(s) in the Draft EIR/EA where the elements are discussed.

According to the CEQ NEPA Regulations, an EA must briefly discuss the following: the need for the proposed action; the proposed action and alternatives as required by NEPA Section 102(2)(E), 42 U.S.C. § 4332(2)(E); the environmental impacts of the proposed action and alternatives; and the agencies and persons consulted during preparation of the EA (40 CFR 1508.9(b)). Table 1-1 identifies each NEPA element with a reference to the corresponding section(s) in the Draft EIR/EA where the elements are discussed. The format and content of this Draft EIR/EA are consistent with the BLM NEPA Handbook (H-1790-1) as listed in Table 1-3.

TABLE 1-3 RECOMMENDED EA SECTIONS AND REQUIRED EIR ELEMENTS

DRAFT EIR/EA SECTION	CEQA REQUIRED ELEMENT/CEQA GUIDELINES	RECOMMENDED NEPA EA SECTIONS
Table of Contents	Table of Contents (Section 15122)	n/a
Executive Summary	Summary (Section 15123)	n/a
Chapter 1	Project Description (Section 15124) Regional Map Project Objectives List of Agencies Expected to Use EIR List of Required Permits and Approvals List of Related Review and Consultation Requirements	Introduction Identifying Information Location of Proposal Purpose and Need for Action and Decision to be Made Scoping and Public Involvement Issues
Chapter 2	Project Description (Section 15124) Precise location and boundaries of the Project Project's Characteristics Alternatives to the Proposed Project (Section 15126)	Proposed Action and Alternatives Description of Proposed Action Description of Alternatives Analyzed in Detail Alternatives Considered but not Analyzed in Detail
Chapter 3	Environmental Setting (Section 15125) Effects Found Not to Be Significant (Section 15128)	Affected Environment
Chapter 4	Environmental Impact Analysis (Section 15126) Significant Environmental Effects Significant Environmental Effects that Cannot Be Avoided Mitigation Measures Cumulative Impacts (Section 15130) Alternatives (15126.6)	Environmental Effects Direct and Indirect Effects Cumulative Effects Residual Effects Identify and analyze mitigation measures, if any
Chapter 5	Long-Term Implications of the Proposed Project (Section 15126.2) Significant Irreversible Environmental Changes Growth-Inducing Impacts	n/a

Chapter 7	References (Section 15129)	n/a

n/a = not applicable

The contents of this Draft EIR/EA are organized in the following manner:

Volume I

- **Executive Summary**—The Executive Summary is provided to afford the casual reader an opportunity to understand the entire Project and its implications. The Executive Summary includes: a brief description of the Project Applicant; lead agency and responsible agency data; a narrative summary of each significant effect with proposed mitigation measures and alternatives that would

reduce that effect; areas of interest known to the lead agencies; and issues to be resolved including the choice among alternatives and whether or how to mitigate the significant effects.

- **Chapter 1**. **Introduction—**The Introduction briefly describes the purpose and need, and Project objectives; location and characteristics of the Project and Alternatives; purpose of NEPA and CEQA and the Draft EIR/EA; and the format and content of the Draft EIR/EA. The Introduction also identifies agencies expected to use the Draft EIR/EA; permits and other discretionary actions required for the Project; related review and consultation requirements; and contact persons for the Draft EIR/EA.
- **Chapter 2**. **Alternatives Including the Proposed Project—**This chapter provides detailed descriptions of the proposed Project and Alternatives. Construction details, operational aspects, and relevant background information are also included.
- **Chapter 3**. **Affected Environment—**This chapter of the Draft EIR/EA describes the existing environmental setting for the Project and the surrounding study area. It also identifies the regulatory framework for each environmental resource topic. Please see Section 1.5 below for a list of the resource topics covered in this Draft EIR/EA.

Volume II

- **Chapter 4. Environmental Consequences Including Cumulative Impacts—**This chapter describes the environmental consequences (direct and indirect impacts) associated with implementation of the proposed Project and Alternatives. It analyzes the potential significant impacts and provides mitigation measures that reduce the magnitude of significant impacts. Residual impacts (impact after mitigation) are also discussed. A discussion of past, present, and reasonably foreseeable future projects and their combined impact with the proposed Project and Alternatives is also included. Please see Section 1.5 below for a list of the resource topics covered in this Draft EIR/EA.
- **Chapter 5. Other CEQA Considerations—**Analyses of significant irreversible environmental changes, growth-inducing impacts, and unavoidable significant environmental impacts (under CEQA) are provided.
- **Chapter 6. Coordination and Consultation—**Organizations and persons consulted during preparation of the Draft EIR/EA. This Chapter identifies persons involved in the preparation of the document.
- **Chapter 7. References**

1.4.2 Volumes III and IV: Technical Appendices

The technical reports that were prepared for the environmental review of the proposed Project are listed below and are provided on the attached CD of this Draft EIR/EA. These reports are referenced at the beginning of each environmental issue area and within the relevant environmental analysis sections of this document. In addition, the Project-specific technical reports included in the appendix and other documents and reference sources that have been used in preparation of this Draft EIR/EA are listed in Chapter 7 (References). The baseline physical conditions as analyzed in these reports are the conditions that existed at the time of the issuance of the Notice of Preparation (NOP) for the Draft EIR/EA (CEQA Guidelines Section 15125(a)) in November 2011. For analytical purposes, the NEPA analysis also uses the November 2011 baseline data.

- Air Quality and Global Climate Change Report
- Biological Technical Report
- 230 kV Transmission Line Alternatives, Habitat Assessment Report
- Western Burrowing Owl Survey Report
- Bird and Bat Conservation Plan
- Review of Federal Waters
- Archeological Resource and Built Environment Survey
- Archeological Resource and Built Environment Survey, Transmission Line Alternative Supplemental Report
- Limited Geotechnical Reconnaissance Evaluation
- Water Supply Assessment

- Blythe Mesa CUP 03685 Wash Feature Summary of Findings
- Paleontological Resource Survey Report
- Traffic Impact Study
- Glare Study

1.5 Scope of the Draft EIR/EA and Known Areas of Interest

1.5.1 CEQA Scoping

Scoping was conducted for this Project to identify the scope of the environmental analysis. An NOP of a Draft EIR/EA for the Project was issued by the County on November 16, 2011. Copies of the NOP were provided to the Office of Planning and Research (State Clearinghouse) for issuance to State agencies. Seventy-five copies of the NOP were distributed to federal, State, and local agencies, responsible and trustee agencies, local governments, private organizations, Native American tribes, and other interested parties. A Scoping Session Notice was sent to 120 property owners within 2,400 feet of the Project boundary. The comment period for the NOP began on November 16, 2011, and ended on December 21, 2011. In compliance with California Code of Regulations (CCR) Title 14, Section 15082(c) (CEQA Guidelines), Riverside County conducted the first public scoping meeting on December 12, 2011. The purpose was to inform the public about the Project; describe the purpose and need of the Project; provide information regarding the environmental review process; and gather public input regarding the scope and content of the Draft EIR/EA. A total of ten comments were received during scoping, all from agencies (one of the ten comments was a courtesy notice from the State Clearinghouse to comment in a timely manner). The comment letters in response to the NOP raised the issue topics listed below. The Scoping Report that contains the comment letters can be found in Appendix A.

- Air Quality
- Public Services and Utilities
- Socioeconomics
- Hazardous Materials/Soils
- Cultural Resources

1.5.2 Water Resources BLM Scoping

On October 4, 2012, the BLM conducted a scoping meeting in Blythe, California. The BLM and Applicant presented information about the Project, alternatives, environmental review process, and potential impacts. A question and answer session was held after the presentation. At the conclusion of the question and answer session, the open house continued and staff members were available to answer questions and gather input. A total of ten individuals attended the meeting. A Public Meeting announcement was mailed to 139 recipients, which included agencies, Native American tribes, organizations, and interested individuals. A newspaper advertisement in the *Palo Verde Valley Times* was published on September 28, 2012, that announced the public meeting date, time, and location.

In addition to the oral comments received at the BLM scoping meeting on October 4, 2012, a total of three comments were received. One comment was made by a concerned citizen on a public comment card. The other two were both from the same individual from a Native American organization. All three copies of the original comments may be found in Appendix A. The issue topics raised by the commenters included:

- Public Services and Utilities
- Socioeconomics
- Cultural Resources
- Hazards

1.5.3 Areas of Interest

The following environmental resources had a potential to be affected by activities related to the proposed Project and Alternatives and are evaluated in this Draft EIR/EA:

- Aesthetics, Visual Resources, and Reflection
- Agriculture
- Air Quality
- Biological Resources
- Cultural Resources
- Geology and Soils
- Greenhouse Gas Emissions
- Hazards and Hazardous Materials
- Hydrology and Water Quality
- Land Use and Planning
- Noise
- Paleontological Resources
- Population, Housing, Public Services, Utilities, and Socioeconomics
- Recreation
- Traffic and Transportation

The following environmental resources are either not present or not impacted by the proposed Project or its alternative, and therefore not discussed in detail in this Draft EIR/EA:

- Forestry
- Mineral Resources
- Livestock Grazing
- Wild Horses and Burros

The Project area and surrounding area do not house any forestry or mineral resources. Accordingly, impacts to these resources are clearly unlikely to occur.

1.6 Agencies Relying on the Draft EIR/EA; Anticipated Permits and Approvals

The table below provides a list of the anticipated federal, State, and local permits and approvals that would be required for the proposed Project and the agencies that are anticipated to rely on the Draft EIR/EA. Other relevant laws, regulations, plans, and policies applicable to the proposed Project are summarized in the resource- and issue-specific sections in Chapter 3. Please refer to Chapter 6, Coordination and Consultation, for a detailed discussion on consultations and persons consulted for the proposed Project and Alternatives.

TABLE 1-4 ANTICIPATED PERMITS AND APPROVALS

ACCEPTING AUTHORITY/ APPROVING AGENCY	PERMIT/APPROVAL	TRIGGERING ACTION	STATUTORY REFERENCE
Federal			
BLM	Grant of ROW and Temporary Use Permit	Proposed gen-tie line construction and operation would occur, in part, on lands under BLM management	Federal Land Policy and Management Act of 1976 (PL 94-579), 43 U.S.C. §§1761-1771; 43 CFR Part 2800. National Environmental Policy Act of 1969 as amended (PL 91-190), 42 U.S.C. §4332, and related statutes
United States Army Corps of Engineers	Nationwide Permit 12	Proposed gen-tie line construction and operation would occur, in part, within waters of the United States	Clean Water Act, Section 404
State of California			
California Department of Fish and Wildlife	Lake or Streambed Alteration Agreement	Proposed construction and operation may potentially impact sensitive biological resources	California Fish and Game Code, Section 1601
State Water Resources Control Board – California Water Quality Control Boards for Colorado River Region	The Applicant must demonstrate compliance with General Discharge Permits for Storm Water Associated with Construction Activity	Proposed construction may involve storm water discharges to surface Waters of the State	Clean Water Act, Section 401
California Department of Transportation, District 8	Encroachment Permit	Proposed construction and operations would occur within and across a California highway ROW	The California Streets and Highways Code, Sections 660 to 734
County of Riverside			
County of Riverside	Conditional Use Permit Public Use Permit Development Agreement	Proposed construction and operation of the Project is located within County jurisdiction	County of Riverside Zoning Ordinance (Ordinance No. 348; CEQA, California Public Resources Code, Sec. 21000 et seq.
	Rezoning, Designation of Agricultural Preserve, Williamson Act Contract Cancellation of Williamson Act Contract and agricultural preserve	Actions taken to encourage agricultural production until all or portions of the site are developed as solar facilities	California Government Code sections 51200 et seq. ; California Government Code section 51282
City of Blythe			
City of Blythe	Conditional Use Permit	Proposed construction and operation of the Project is located within the City limits	City of Blythe, Code of Ordinances, Title 17, Zoning

1.6.1 Related State and Local Review and Consultation Requirements

Ancillary permits, including encroachment permits, grading and construction permits, and certificates of occupancy, are anticipated from the County and the City. These permits and approvals are local ministerial actions that are parallel to or follow CEQA compliance. Other State and local agencies or regulatory entities that could exercise authority over specific elements of the proposed Project include:

- Riverside County Airport Land Use Commission (ALUC): On April 12, 2012, the ALUC reviewed the proposed solar facility layout, transmission components, glint and glare analysis, and ancillary facilities and found the Project consistent with the 2004 Blythe Airport Land Use Compatibility Plan subject to a number of conditions.

- California Department of Transportation, District 8: An encroachment permit would be needed for any Project construction and operations that occur within or across a California highway ROW.

- California Department of Fish and Wildlife (CDFW): Informal consultation has occurred with the CDFW, Inland Desert Region, concerning the scope of biological resource studies and species of interest relative to the proposed Project on private lands.

- Mojave Desert Air Quality Management District (MDAQMD): Permits regulating air pollutant emissions during Project construction, operation, maintenance, and decommissioning are anticipated to be issued by the MDAQMD upon demonstration that the Project will comply with local air regulations.

- Palo Verde Irrigation District (PVID)/County Service Area #22: The Applicant has consulted with the PVID regarding the availability of water supplies to serve the proposed Project, including preparation of Water Supply Assessment pursuant to State law. The Applicant has consulted with and received a will-serve letter from the potable water purveyor, County Service Area #22.

- Native American Heritage Commission (NAHC): In April 2011, prior to the commencement of archeological field surveys of the Project area, the Applicant submitted a letter to the NAHC. The letter requested a list of Native American tribes that should be contacted for information about cultural resources that may occur on or in close proximity to the proposed Project area, as well a Sacred Lands File search. Information requests were submitted to the listed Tribes via United States mail.

- California Independent System Operator (CAISO): The Applicant has applied for and been granted a reservation by CAISO for a secured interconnection queue position sufficient for the size of the Project at the Colorado River Substation. This is a necessary element of being able to transmit generated power to the statewide electric grid.

Additional legislative enactments may be sought from Riverside County by the Applicant, but these would not change the physical aspects of the Project or its impacts. The Project is being pursued pursuant to land use amendments recently adopted by Riverside County. These include General Plan Amendment 1080, which added Land Use Policy LU-15.15, stating: “Permit and encourage, in an environmentally and fiscally responsible manner, the development of renewable energy resources and related infrastructure, including but not limited to, the development of solar power plants in the County of Riverside.” In connection with GPA 1080, Riverside also enacted Ordinance No. 348.4705, which amended the zoning code to allow a solar power plant on a lot 10 acres or larger in certain zoning districts,[2] upon issuance of a use permit.

1.6.2 Related Federal Review and Consultation Requirements

In addition to complying with NEPA, the BLM will comply with other federal regulations and authorizations and conduct necessary consultations regarding the resources potentially affected by the proposed Project. Such consultations include but are not limited to:

[2] The zoning districts are: General Commercial (C-1/C-P), Commercial Tourist (C-T), Scenic Highway Commercial (C-P-S), Rural Commercial (C-R), Industrial Park (I-P), Manufacturing Servicing Commercial (M-SC), Medium Manufacturing (M-M), Heavy Manufacturing (M-H), Mineral Resources (M-R), Mineral Resource and Related Manufacturing (M-R-A), Light Agriculture (A-1), Light Agriculture with Poultry (A-P), Heavy Agriculture (A-2), Agriculture-Dairy (A-D), Controlled Development (W-2) , Regulated Development Areas (R-D), Natural Assets (N-A), Waterways and Watercourses (W-1), and Wind Energy Resource Zone (W-E).

- United States Fish and Wildlife Service (USFWS): The USFWS has jurisdiction to protect threatened and endangered species under the Endangered Species Act (ESA) (16 U.S.C. § 1531 et seq.). Under Section 7 of the ESA, the BLM is obligated to conduct informal and, if necessary, formal consultation with the USFWS relative to federal actions that may adversely affect a federally listed species. BLM conducted informal consultation, which resulted in the USFWS issuing a determination letter that the Project would not likely adversely affect federally listed desert tortoise (see Appendix M of this Draft EIR/EA). Therefore, an ESA Section 7 formal consultation is not required.

- Section 106 of the National Historic Preservation Act (NHPA), as amended, 16 U.S.C. §470f, (36 CFR Part 800), requires federal agencies to take into account the effects of a proposed undertaking on historic properties and to afford the Advisory Council on Historic Preservation (ACHP) a reasonable opportunity to comment (36 CFR Part 800.1(a)). The Section 106 process seeks to accommodate historic preservation concerns with the needs of federal undertakings through consultation among the agency official and other parties with an interest in the effects of the undertaking on historic properties. The goal of consultation is to identify historic properties potentially affected by the undertaking, assess the undertaking's effects, and seek ways to avoid, minimize, or mitigate any adverse effects on historic properties (36 CFR Part 800.1). As required by Section 106, the BLM sent a consultation letter to the ACHP on August 7, 2013, summarizing its determinations of NRHP eligibility for cultural resources within the area of potential effect and its findings of effect.

    - On August 7, 2013, the BLM notified the State Historic Preservation Officer (SHPO) about the Project and requested initiation of formal consultation regarding the undertaking, which follows the procedures of 36 CFR Part 800.2(c)(1)). The letter also summarized the BLM's determinations of eligibility for cultural resources within the area of potential effect and its findings of effect.
    - Tribal Consultation: As part of the Section 106 process of the NHPA (36 CFR Part 800.2(c)(2)), the BLM has consulted directly with Native American tribes regarding properties of cultural or religious significance that may be affected by the proposed action.

- Government-to-Government Consultation: In addition to the requirements of the NHPA and NEPA, the BLM is required to consult with Native American tribes according to *Executive Order 13175, Consultation and Coordination with Indian Tribal Governments*, which directs federal agencies to establish regular and meaningful consultation and collaboration with tribal officials in the development of federal policies that have tribal implications, to strengthen the United States government-to-government relationships with Native American tribes, and to reduce the imposition of unfunded mandates upon Native American tribes. Also, the Presidential *Memorandum for the Heads of Executive Departments and Agencies Regarding Government-to-Government Relations with Native American Tribal Governments,* issued November 5, 2009, directs executive departments and agencies to engage in regular and meaningful consultation and collaboration with tribal officials in the development of federal policies that have tribal implications, and to strengthen the government-to-government relationship between the United States and Native American tribes. Government-to-government consultation between the BLM and tribal governments is an on-going process that will continue even after the Section 106 process for the proposed Project has been completed.

- Federal Aviation Administration (FAA), Objects Affecting Navigable Airspace: In conjunction with ALUC project review, the Applicant submitted tower structure locations and other relevant Project features to the FAA for formal hazard determination under 49 U.S.C. §1501; 13 CFR Part 77, Objects Affecting Navigable Airspace. In April 2012, the FAA conducted aeronautical studies (Aeronautical Study Nos. 2012-AWP-551-OE, 2012-AWP-552-OE, 2012-AWP-562-OE, 2012-AWP-566-OE through 2012-AWP-571-OE, 2012-AWP-573-OE, 2012-AWP-1712-OE through 2012-AWP-1725-OE) and issued "No Hazard to Air Navigation" Determinations for the 230 kV gen-tie line structures (see Appendix N of this Draft EIR/EA). Prior to construction, the Applicant must submit a Notice to Construct (FAA Form 7460-2) and receive authorization from FAA.

- United States Army Corps of Engineers (USACE) Jurisdictional Waters: The USACE has jurisdiction to protect the aquatic ecosystem, including water quality and wetland resources, under Section 404 of

the Clean Water Act (CWA). Under that authority, the USACE regulates the discharge of dredged or fill material into waters of the United States, including wetlands, by reviewing proposed projects to determine whether they may impact such resources and, thereby, are subject to a Section 404 permit. The Applicant has informally consulted with the USACE to assist the agency in making a determination regarding its jurisdiction and the need for a Section 404 permit. The determination is pending.

1.7 Contact Persons

Please contact the following individuals regarding questions and concerns about the Project:

CEQA Lead Agency:
Larry Ross, Principal Planner
Riverside County Planning Department
4080 Lemon Street, 12th Floor
P.O. Box 1409
Riverside, CA 92502-1409

NEPA Lead Agency:
Frank McMenimen, Project Manager
Bureau of Land Management
Palm Spring South Coast Field Office
1201 Bird Center Drive
Palm Springs, CA 92262

CHAPTER 2: ALTERNATIVES INCLUDING THE PROPOSED PROJECT

2.1 Overview

The California Environmental Quality Act (CEQA) and National Environmental Policy Act (NEPA) both require consideration of a reasonable range of alternatives to the proposed Blythe Mesa Solar Project (Project) that would attain most of the basic objectives of the Project or meet the United States Department of the Interior, Bureau of Land Management's (BLM's) purpose and need. CEQA requires that decision-makers adopt mitigation measures or alternatives that would avoid or substantially lessen any of the significant effects of the Project, and the Environmental Impact Report (EIR) must contain sufficient information to allow them to do so. Under NEPA, the analysis of alternatives in an Environmental Assessment (EA) need not be as comprehensive and detailed as the alternatives analysis required for an Environmental Impact Statement (40 Code of Federal Regulations [CFR] Part 1508.9(b)). Chapter 1 describes the purpose and need for the Project and Project objectives. This chapter addresses the development of the range of alternatives considered; provides a detailed description of the proposed Project and alternatives, selected for detailed study, and describes the alternatives considered and eliminated from further analysis.

2.1.1 Overview of Solar Technology

Solar cells, also called photovoltaic (PV) cells, convert sunlight directly into electricity. PV gets its name from the process of converting light (photons) to electricity (voltage), which is called the *PV effect.* PV cells are located on panels, which are mounted at a fixed angle facing south or on a tracking device that follows the sun, allowing them to capture more sunlight than a fixed mount system. Many solar panels on multiple rows combined together and controlled by a single motor create one system called a solar tracker. For large electric utility or industrial applications, hundreds of solar trackers are interconnected to form a large utility-scale PV system.

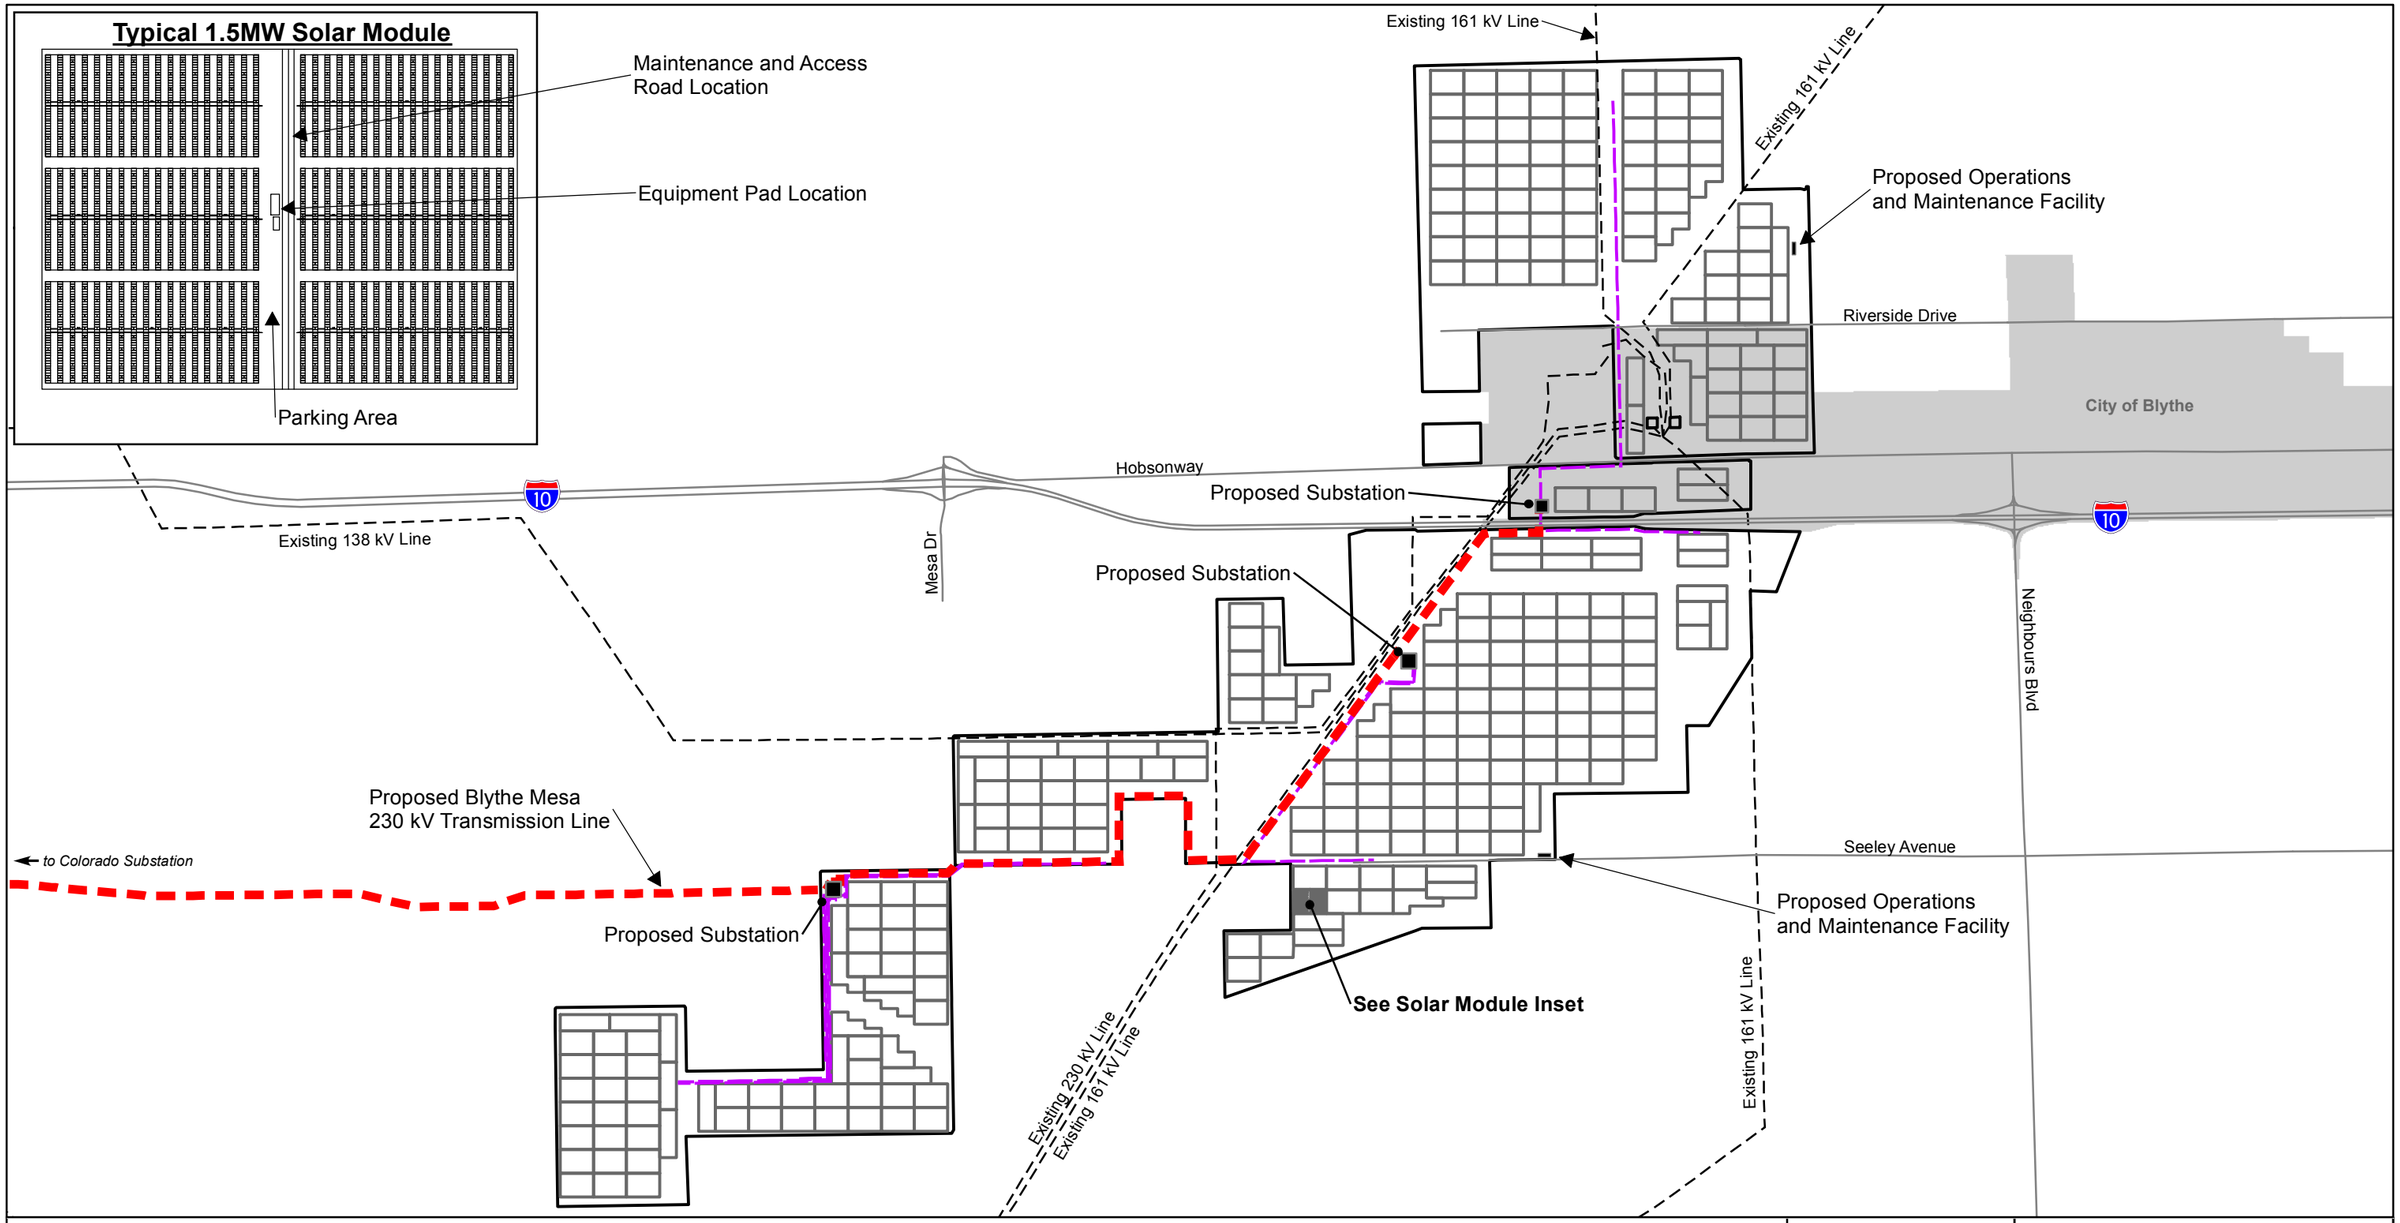
2.1.2 Insolation

Insolation is a measure of solar radiation energy received on a given surface in a given time. It is commonly expressed as an average irradiance in watts per square meter (W/m^2) or kilowatt-hours per square meter per day ($kWh/m^2/day$). The Blythe area receives anywhere between 6.0 and 7.0 $kWh/m^2/day$ of solar radiation energy, giving it a higher degree of solar radiation than most areas within the United States (NREL 2012).

The amount of the sun's heat absorbed by a solar panel is similar to the amount of the sun's heat absorbed by the earth. Solar panels, however, store less heat than the earth. A solar panel is thin—the glass is approximately 3.0 millimeters (0.12 inch) in thickness—lightweight, and surrounded by airflow (because it is mounted above the ground). Therefore, heat dissipates quickly from a solar panel. The normal operating condition temperature for solar panels would be 20 degrees Celsius (°C) or 68 degrees Fahrenheit (°F) above ambient temperature, and so a typical summer day at 40°C (104° F) results in panel temperatures of approximately 60°C (140°F). When accounting for irradiance, wind, and module type, it is expected that the peak module temperatures would be between 35°C and 40°C (95°F and 104°F). Although the panels would be hot to the touch, the temperature below the panels would be nearly the same as ambient temperatures in the ordinary shade.

2.2 Alternative 1: Proposed Project

The Project would consist of the construction, operation, maintenance, and decommissioning of an up to 485 megawatt (MW) alternating current solar PV electrical generating facility and associated infrastructure to provide site access and connection to the statewide electricity transmission grid.



The Project is proposed to be located on approximately 3,660 acres in the Palo Verde Mesa region of Riverside County—approximately 3,587 acres for the solar field and 73 acres for the 230 kilovolt (kV) generation interconnection (gen-tie) line. The power produced by the Project would be conveyed to the local power grid via interconnection to the Southern California Edison (SCE) Colorado River Substation, an approved new substation located south of Interstate 10 (I-10) and approximately four miles west of the Project site. The Project has secured a California Independent System Operator (CAISO) interconnection queue position sufficient for the size of the Project. The Project would produce enough energy to power approximately 180,000 households and progress the goals of the California Renewable Portfolio Standard (RPS) and other similar renewable programs in the state. The Project would also assist in meeting President Obama's Climate Action Plan, which set a goal of issuing an additional 10 gigawatts of renewable electric generation on public lands by 2020.

The proposed Project would consist of the following components (see Figure 2-1):

- **Solar facility site (3,587 total acres)**
    - Solar array field that would utilize single-axis solar PV trackers (295 feet long and 140 feet. wide). Six trackers with 18 north-south oriented rows of PV panels would be configured into 1.5 MW blocks (600 feet long by 470 feet wide).
    - System of interior collection power lines (34.5 kV) located between inverters and substations.
    - Up to three on-site substations (each approximately 90,000 square feet).
    - Up to two operations and maintenance (O&M) buildings (approximately 3,500 square feet each).
    - Associated communication facilities and site infrastructure.
    - Two primary off-site access roads and several interior access roads.
- **Approximately 8.4 miles of 230 kV gen-tie transmission line**
    - Approximately 3.6 miles would be located within the solar facility, which would connect all on-site substations.
    - Approximately 4.8 miles would extend outside of the solar facility and would be placed within a 125-foot-wide right-of-way (ROW) and occupy 73 acres.

The fenced-in solar PV electric generation facility would occupy approximately 3,587 acres on privately owned land (approximately 3,253 acres are within the County of Riverside and approximately 334 acres are within the City of Blythe). The portion of the gen-tie line outside the solar facility site, from the southernmost substation to the Colorado River Substation, would traverse 3.8 miles of BLM-managed lands (approximately 58 acres) and approximately one mile of private land (approximately 15 acres). The term "Project area" is used in this document to refer to the proposed 485 MW solar PV facility and associated infrastructure (3,587 acres), as well as the proposed 230 kV transmission line (gen-tie line) (73 acres).

The BLM's action options would be to deny the proposed ROW grant, grant the ROW, or grant the ROW with modifications. The BLM may include any terms, conditions, and stipulations it determines to be in the public interest, and may include modifying the proposed use or changing the route or location of the proposed facilities (43 CFR Part 2805.10(a)(1)).

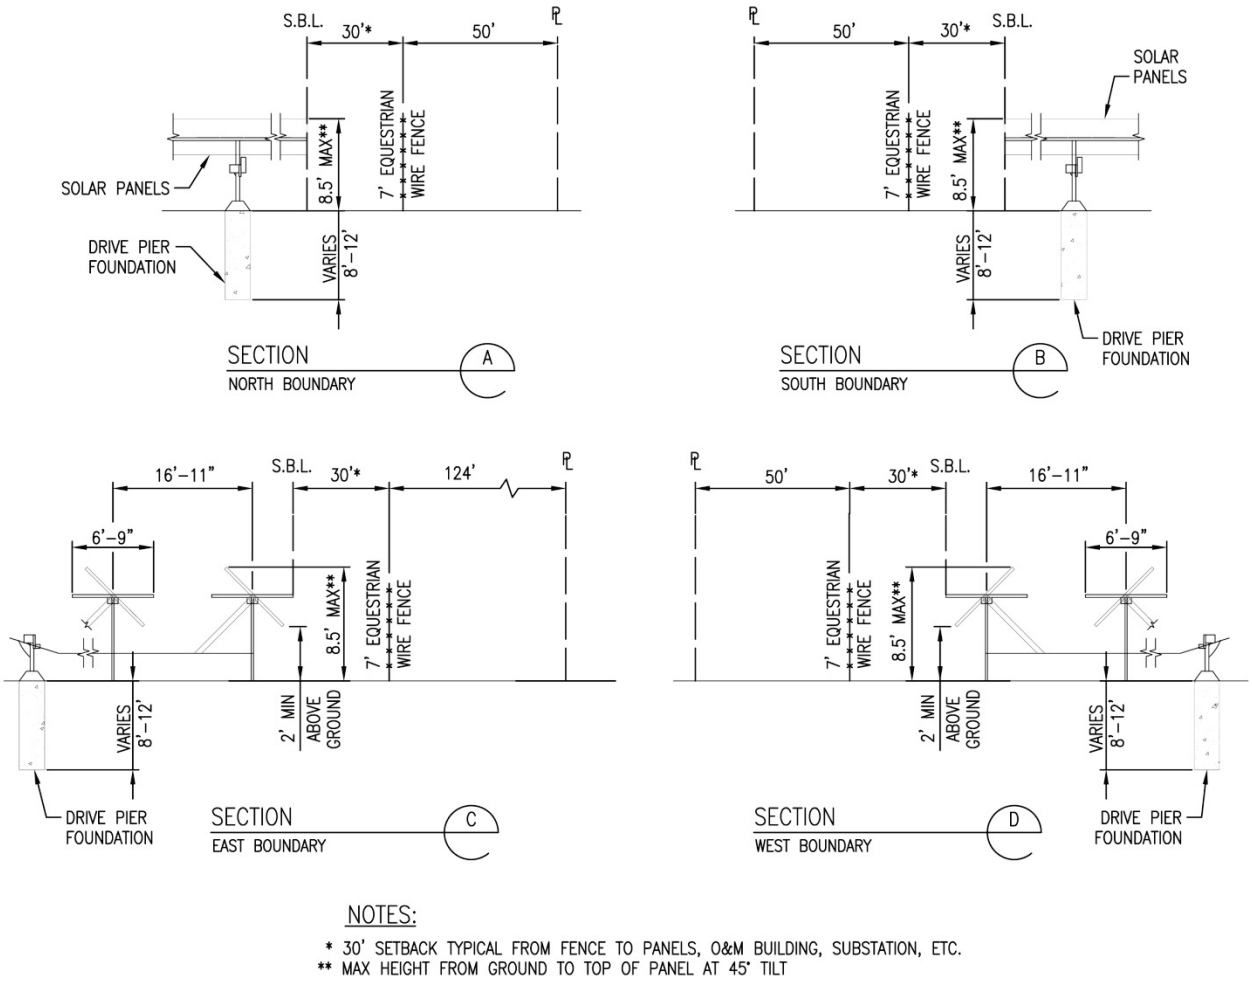
THIS PAGE INTENTIONALLY LEFT BLANK

2.2.1 Project Facilities

Solar Array Field



The Project would utilize single-axis PV trackers with approximately 1,425,600 high-efficiency, monocrystalline, silicon solar panels. The panels would be configured into trackers, and the trackers configured into blocks approximately 660 feet wide and 470 feet long (refer to Figure 2-2). Each block comprises six trackers with 18 north-south oriented rows of PV panels (295 feet long and 140 feet wide) that rotate up to 45 degrees from east to west to track the sun (total number of rows is 35,640), with the center of rotation being approximately four to eight feet above grade (refer to Figure 2-3). Solar panels at an upright position would have a minimum clearance of 24 inches above the highest adjacent ground. Within each tracker, the rows of PV panels would be linked by a steel drive strut (295 feet long), which would be oriented perpendicular to the axis of rotation. Each row would be connected to the drive strut by a torque arm, which acts as a lever, enabling the drive strut to rotate the rows in unison. A small 0.5-horsepower electric drive motor would move the drive strut back and forth and is typically mounted in the center of a block. The drive motor would be placed on a concrete foundation that is approximately 2.5 feet in diameter and a minimum of 1.5 feet above ground level. Torque tubes act as the horizontal support for the PV panels and are in turn supported by micro piles (15 to 20 feet long and having a 4.5-inch outer diameter), which are driven directly into the ground (i.e., no concrete footings are used) and are able to withstand high-wind conditions as required under International Building Code (IBC) occupancy classification U. The metal structural elements would be constructed of corrosion-resistant galvanized steel.

FIGURE 2-2 TYPICAL 1.5 MW SOLAR ARRAY

AR062316

FIGURE 2-3 TRACKER SPECIFICATIONS

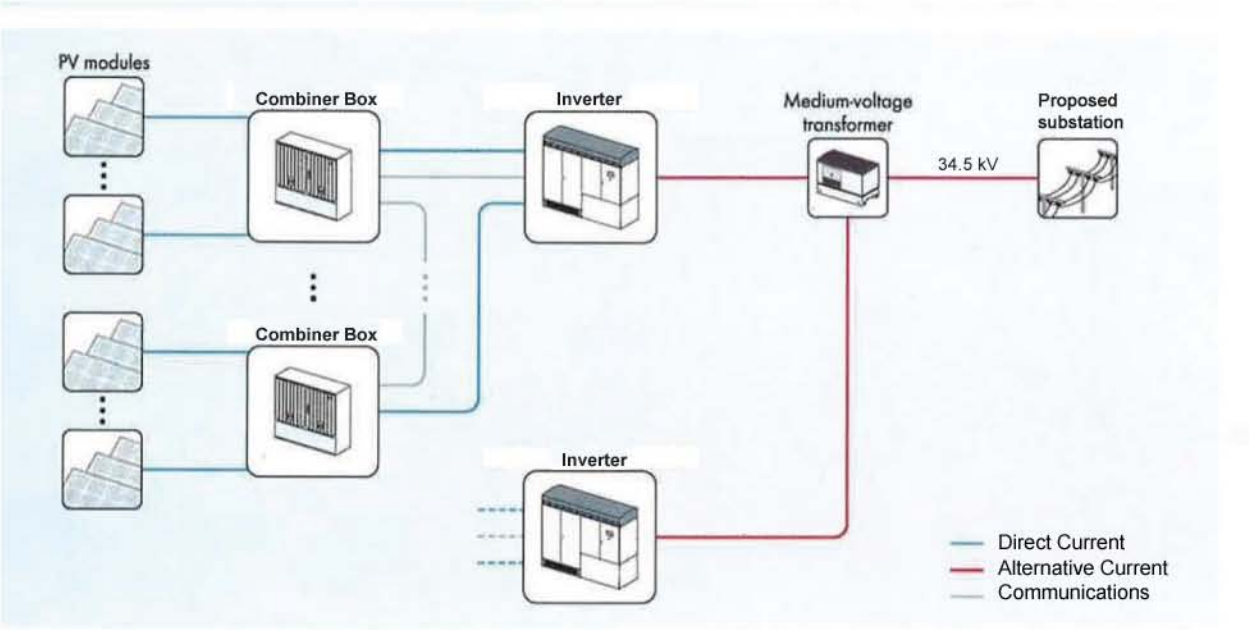
Combiners, Inverters, and Transformers

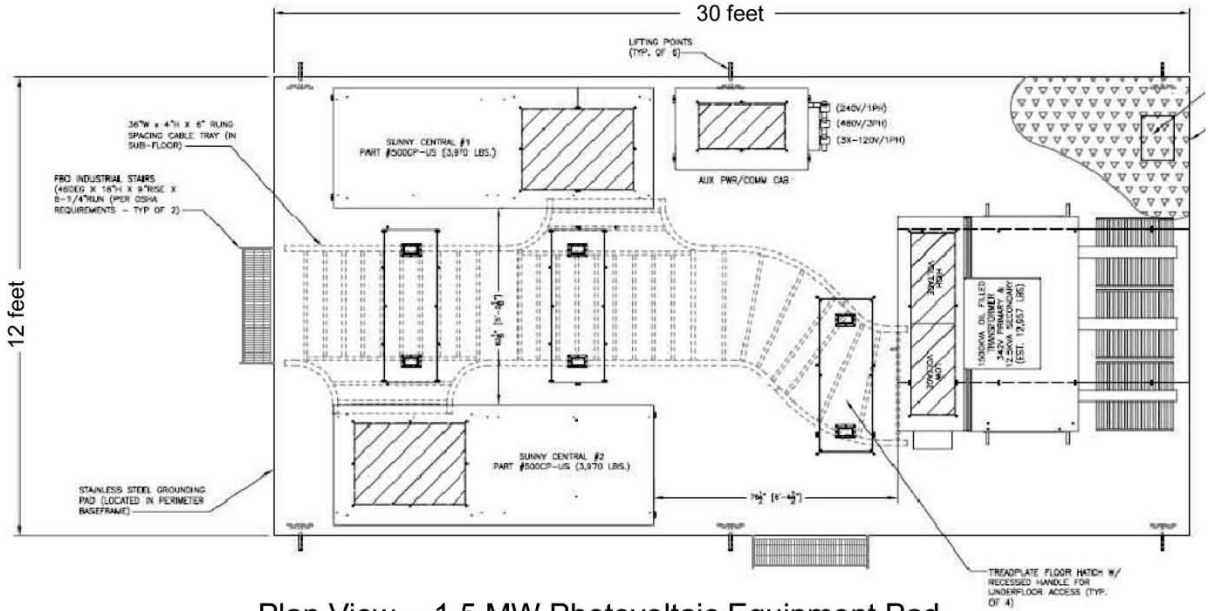
Individual PV panels would be connected together in series to create a "string" to carry direct current (DC) electricity. Multiple DC strings would be brought together into an above-ground combiner box to merge the strings into a single high-current cable and provide overcurrent protection. From the combiner boxes, the cabling would run in raceways and underground to inverters (5.0 feet wide and 10.5 feet tall) mounted on small concrete pads (minimum 0.5 foot above grade) distributed across the site. The inverters would take the DC output from the combiner boxes and convert it to alternating current (AC) electricity. Figure 2-4 illustrates the process from PV panels to the proposed substation.

Installation of the electrical collection system would require excavations to a depth of about three feet for underground electrical circuits.

Next, the AC electricity would be increased to medium voltage (34.5 kV) with a standard "step-up" transformer. The medium-voltage collection lines would begin at the inverter/transformer pads and would be located in trenches about three feet deep until the output from 10 to 15 blocks is gathered and transferred at risers to a system of overhead medium-voltage collection lines for transmission to the substations (Figure 2-5). The medium-voltage collection circuits would be mounted above-ground on poles 35 to 60 feet tall, have an average tower to tower span of approximately 200 feet, and carry 20 to 30 MW of electricity (see Figure 2-6). To the extent possible, the poles would be located along the northern edge of the blocks.

FIGURE 2-4 PV PANELS TO PROPOSED SUBSTATION





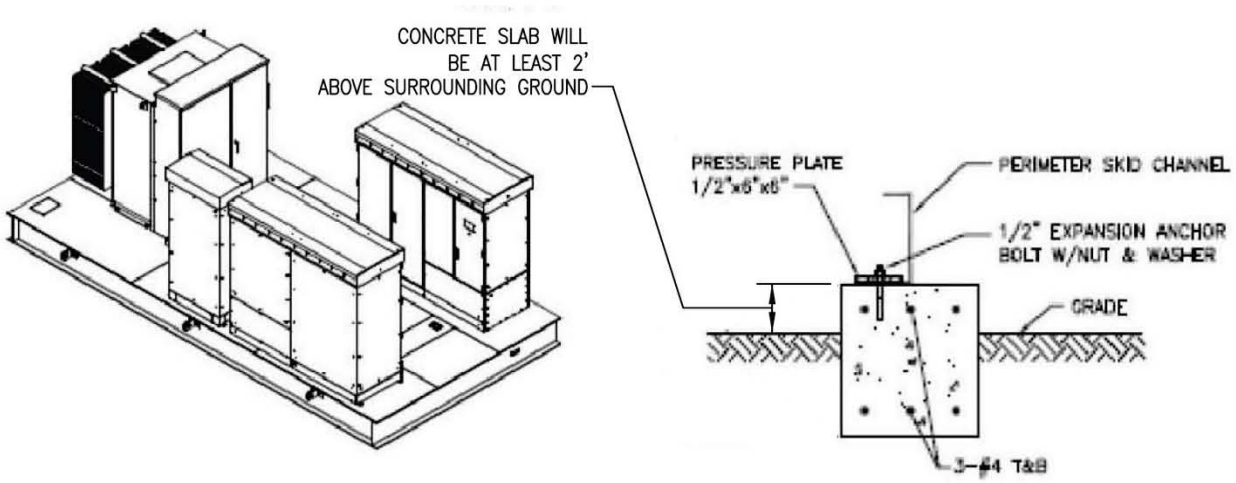


FIGURE 2-5 EQUIPMENT PAD CONTAINING INVERTER AND TRANSFORMER

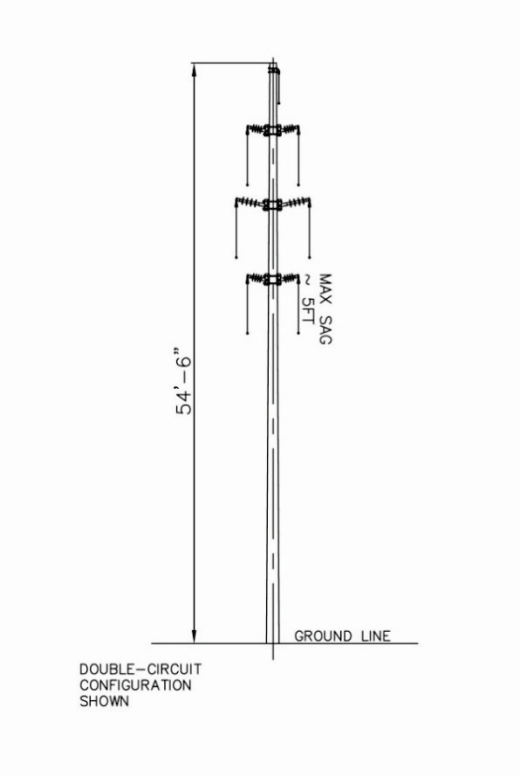

Plan View -- 1.5 MW Photovoltaic Equipment Pad

INVERTER/TRANSFORMER EQUIPMENT PAD

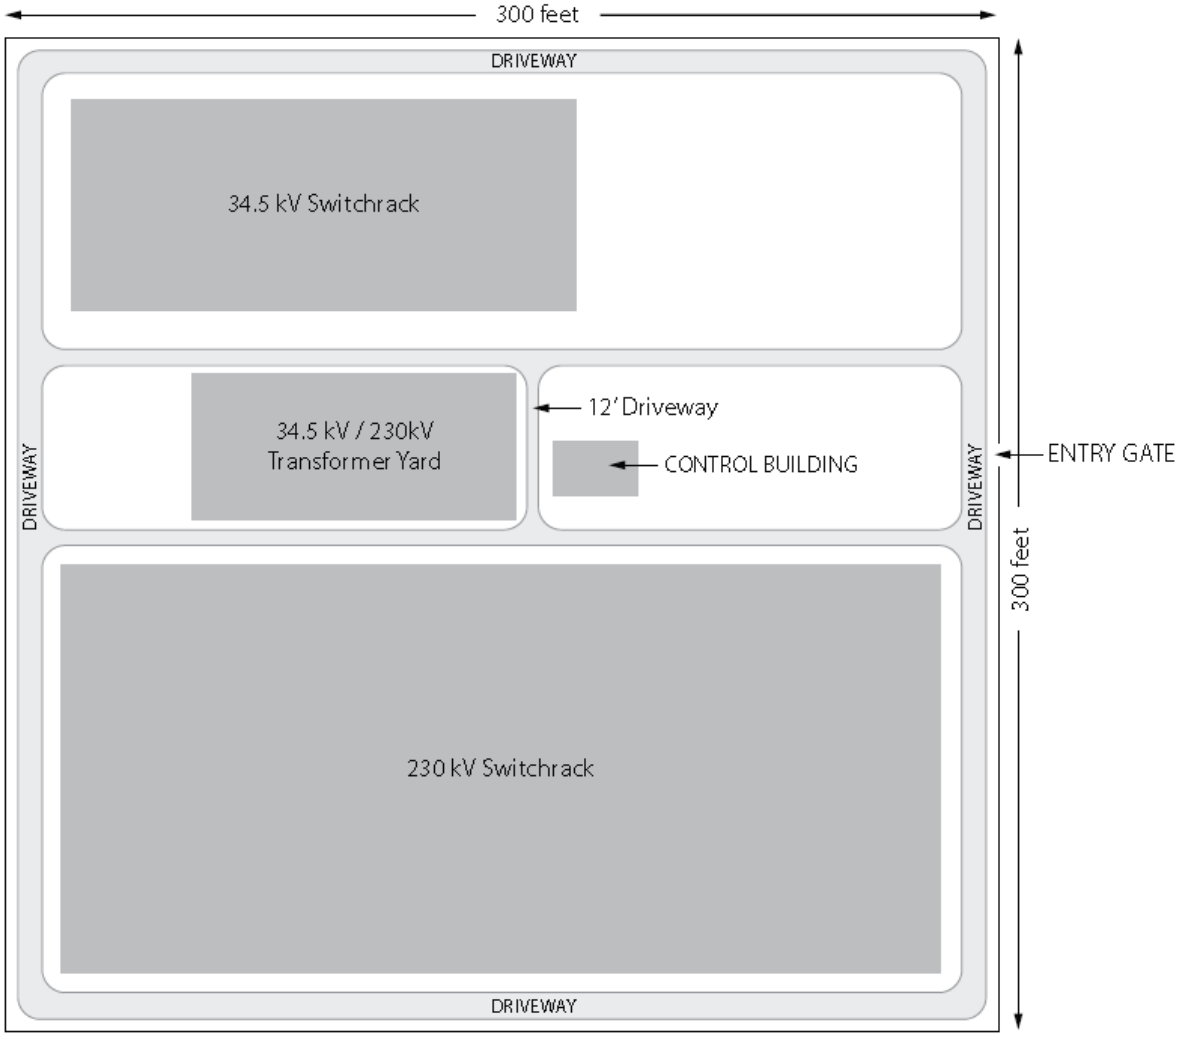

FIGURE 2-6 MEDIUM VOLTAGE OVERHEAD POLES

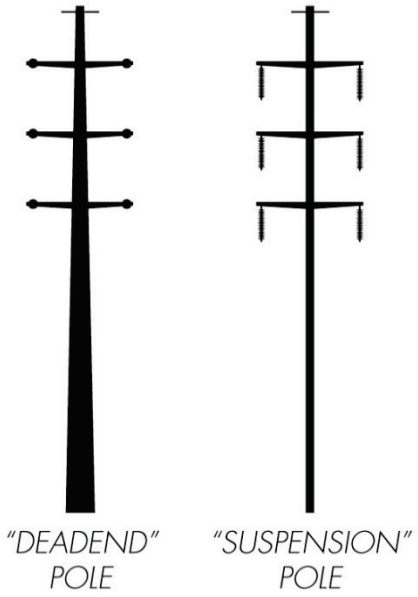
Substation and Switchgear Pads

The three Project substations (each approximately 300 feet long by 300 feet wide) would collect all the medium-voltage circuits and step up the voltage to 230 kV. The internal arrangement for the substations would include a 34.5 kV switchrack and outdoor breaker assemblies, 230 kV outdoor breakers and switches, a 34.5 kV / 230 kV transformer yard, and a control building (see Figure 2-7). The substation foundations would be a minimum of 24-inches above the highest adjacent ground.

FIGURE 2-7 INTERNAL SUBSTATION ARRANGEMENT



Substation and Switchgear Pads

The Applicant proposes to construct an approximately 8.4-mile-long, 230 kV overhead gen-tie line from the proposed on-site substation located just north of I-10 to the Colorado River Substation that is currently under construction. Approximately 3.6 miles of the gen-tie line would be located within the solar facility. From the southernmost substation to the Colorado River Substation, the gen-tie line would extend another 4.8 miles within a 125-foot-wide ROW (3.8 miles would traverse BLM-managed lands and one mile would traverse private land). The gen-tie line would run parallel to and immediately south of the 500 kV Desert Southwest Transmission Line corridor.

The gen-tie line facilities would include a set of double-circuit tubular steel poles (only one circuit would be strung and the other circuit would be vacant) that are 85 to 125 feet tall with an average tower-to-tower span length of 500 to 800 feet (see Figure 2-8). Structure heights and corresponding span lengths meet Federal Aviation Administration (FAA) requirements for the nearby Blythe Airport. The suspension poles would typically be four to six feet in diameter. At angle or dead-end points along the gen-tie path, larger poles would be required that would be approximately six to ten feet in diameter. The poles would be directly embedded in the soil or set in concrete foundations approximately 20 to 30 feet deep. Concrete foundations, if used, would typically extend one foot laterally beyond the base of the poles, adding up to

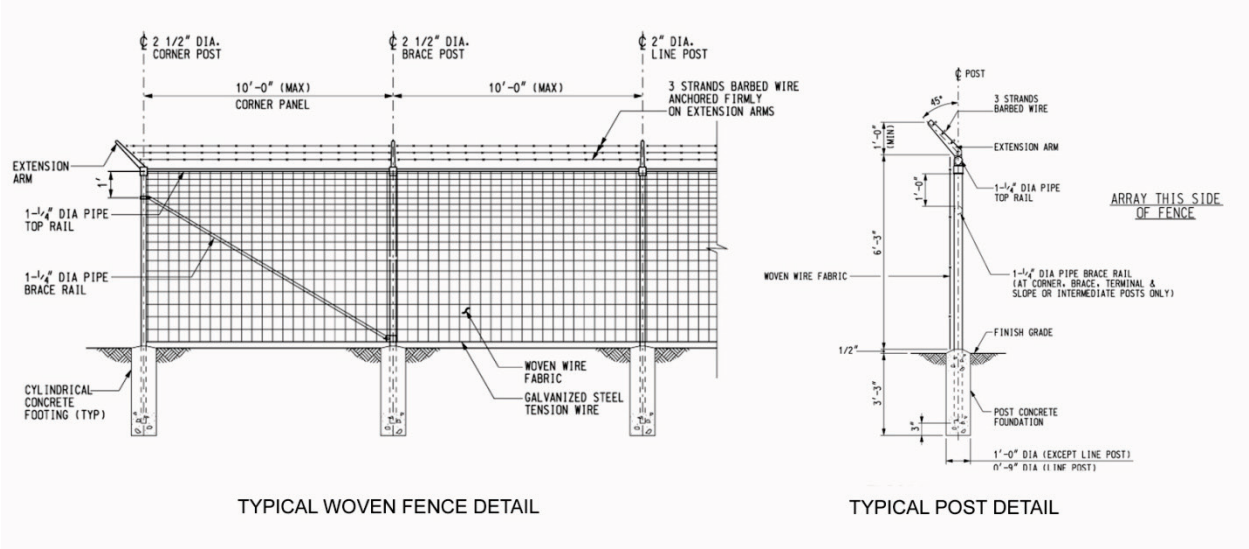
two feet to the overall diameter of the permanent footprint of each pole location. Temporary access roads to each structure would be 12 to 16 feet wide, covered with eight inches of gravel over compacted sub-grade, and located within the proposed ROW.

FIGURE 2-8 GEN-TIE LINE POLES

Operation and Maintenance Buildings

Up to two O&M buildings (approximately 3,500 square feet each, enclosed, and no more than 20 feet tall) would provide work space for maintenance staff and storage space for spare parts. The locations of the buildings are shown in Figure 2-1 with the layout and elevations illustrated in Figures 2-9 and 2-10. The buildings shall be constructed with the finished floor a minimum of 24-inches above the highest adjacent ground. The building would include bathroom facilities serviced by a private septic system and would be designated occupancy classification U. A covered outdoor temporary assembly and storage area (80,000 square feet, 25 feet tall) would be directly adjacent to the O&M building(s).

Access Roads



Two access points to the solar facility are planned on Seeley Avenue and Riverside Drive; both accessible from the Neighbors Boulevard off-ramp from I-10 (see Figure 2-1). The primary access roads would be improved at the entrance to the site for 100 feet and would be 16 to 20 feet wide.

Unpaved access roads within the solar field would be 12 feet wide and constructed approximately every 200 to 400 feet to allow access to and maintenance of the solar panels.

Other Infrastructure

The solar facility would be enclosed with fencing that meets National Electric and Safety Code (NESC) requirements for protective arrangements in electric supply stations, such as a seven-foot-tall, equestrian-type wire fence along the perimeter (see Figure 2-11). This type of fence allows smaller wildlife to enter and exit the solar facility site, as well as allows water to flow through. The fence would typically be set 30 feet from the edge of the solar array.

FIGURE 2-11 FENCE DETAILS

2.2.2 Construction

Site Preparation

Since most of the site has nearly level to gently sloping topography, no mass grading would be required. Some of the parcels where facilities and arrays would be located would require light grubbing for leveling and trenching. Access roads would require minimal grading. After grubbing and light grading, construction of staging areas would occur. On-site pre-assembly of trackers would take place in the assembly area.

The PV system proposed for the site can operate on slopes up to nine percent in all directions. Fine grading would only be required for the development of site access. During construction, it is anticipated that a total of up to approximately 1,354 acre-feet (AF) of water (451 AF per year) would be utilized for soil moisture conditioning and dust control (final use numbers will be further refined pre-construction).

Minor demolition of existing site structures (e.g., storage buildings in citrus grove, three on-site residences) would be required.

Installation of the electrical collection system would require excavations to a depth of about three feet for underground electrical circuits, inverter and switchgear enclosure foundations, and transformer foundations. The O&M building foundations would also be excavated to a depth of about three feet.

THIS PAGE INTENTIONALLY LEFT BLANK

Construction Activities

To ensure study of the maximum intensity of construction impacts, the Project is studied based upon an assumption that there would be continuous construction activity over a period of approximately three years, which represents the shortest reasonable construction period. The Project may in fact be constructed in several phases at several different times over a longer time frame.

For purposes of the Draft EIR/EA, it is assumed that the Project would be constructed in the following phases, which would occur simultaneously on different portions of the site:

- Development of staging areas and assembly areas, and grading of site access roads.
- Construction of arrays including pile installation, assembly of trackers, mounting of PV panels, and trenching and installation of electrical equipment for arrays.
- Construction of electrical transmission facilities including the construction of three substations, the 230 kV gen-tie line, and up to two O&M buildings.

Staging Areas, Assembly Areas, and Access Roads

Construction staging and material lay-down would be distributed across the solar facility evenly to allow for efficient distribution of components to different parts of the Project. One staging and material lay-down area would typically be set up for every 100 acres of the Project site. These lay-down areas would be temporarily fenced and would cover approximately five acres each. Lay-down areas would be converted to solar arrays as work is completed in the general area. Within the solar field, 12-foot-wide access roads would also be constructed approximately every 200 to 400 feet to allow access to and maintenance of the solar panels.

Array Assembly

Tracker assembly may include up to 25 small gas-powered generators to power welding machines to assemble trackers and construct tracker arrays. Support piles up would be driven into the ground to a depth of eight to twelve feet using a vibration technology to reduce noise impacts. Torque tubes, electrical wire trays, and panels would then be installed on the piles. Concrete foundations for the drive motors would be poured in place, and electrical equipment for the array would be set in place. A tracked backhoe would drive piles. No blasting or rock breaking is anticipated or proposed. Small truck-mounted cranes or grade-all forklifts would place trackers on support tiles. Tracker installation would include small all-terrain vehicles to transport materials and workers on access roads and array aisles.

Substations

Construction of the substations would involve site preparation, clearing of the switchrack sites, and installation of substructures and electrical equipment. Each site would first be cleared and graded, and then security-fenced for the duration of substation construction. Underground Service Alert would be contacted to mark the locations of existing buried utilities in the vicinity. Substation materials and equipment would be delivered to, and stored at, the substation site, as required, during construction. The sites would be graded to maintain current drainage patterns as much as possible.

Each substation would be constructed with conventional grading and construction equipment. Grading would establish the desired site grade, and minor excavation would provide concrete footings for the substation equipment. The substation sites would be graveled with crushed rock for grounding and employee safety purposes.

O&M Buildings

The O&M building areas would be surveyed and staked. A concrete slab would be poured to the dimensions of each building. The prefabricated steel building structures would then be assembled. The

exterior finish would be constructed as the mechanical and electrical systems are built inside. Interior finishing would follow, and final fixtures and equipment would be installed.

Gen-tie Line

The gen-tie line construction would involve the following activities: (1) construction of staging areas for trailers, office personnel, equipment, material staging, lay-down, and employee parking; (2) construction of access roads to the structure locations; (3) pole erection; (4) conductor installation; (5) tension and pulling sites of conductors; and (6) installation of overhead ground/fiber optic communications systems.

Construction Sequence, Equipment, and Workforce

For the purposes of the Draft EIR/EA, construction is anticipated to occur over a three-year period with the construction activities described above occurring simultaneously; peak construction would occur over 24 months. The solar field would be developed in six-month phases, with six blocks constructed at a time (each block 100 acres, for a total of 600 acres at a time). Construction of the substations, gen-tie line, switchyard, and up to two O&M buildings would occur as the arrays are being assembled. The timing and workforce used for each construction activity/phase is illustrated in Table 2-1. After the common facilities (e.g., substations, switchyards, O&M building(s)) are completed in the earlier stages, the workforce would be devoted more to array construction in the later stages.

Approximately 500 daily workers would be present on-site during peak construction. Workers would gain primary access to the site using Seeley Avenue and Riverside Drive off of Neighbors Boulevard. Worker construction traffic would consist of approximately 400 daily vehicle roundtrips (300 employees would travel alone, and 200 employees would carpool). It is anticipated that most workers would be drawn from the Blythe/Palo Verde Valley region and the Desert Center region, with a smaller portion drawn from the Imperial Valley or Eastern Riverside County region. Anticipated average daily material deliveries would consist of about 20 truck deliveries per day for 24 months. Workers and delivery trucks would access the site using the Neighbors Boulevard off-ramp from I-10. Typical on-site work hours would be from 7:00 a.m. to 6:00 p.m. During the installation period, construction workers are projected to be on-site five days per week, year-round. Due to weather or other major-type delays, times may shift to start as early as 5:00 a.m. and end as late as 8:00 p.m., as well as continue into the weekends. However, in compliance with Noise Ordinance 847, construction within 0.25-mile from a residence would be prohibited during non-typical work hours. Security would be on-site 24 hours per day.

TABLE 2-1 DURATION AND NUMBER OF WORKERS OF EACH CONSTRUCTION PHASE*

CONSTRUCTION ACTIVITY/PHASE	DURATION	WORKERS
Site Preparation/Clearing/Grading	6 months	20
Staging and Assembly Areas (including access roads)	6 months	20
Construction of Solar Array, Substations, O&M Building(s)	24 months	200-500
Installation of 230 kV Gen-tie Line and Fiber Optic Cable	12 months	30
Testing	3 months	20
Clean up/restoration	1 month	20

*Construction would occur over a three-year period with construction activities occurring simultaneously.

During construction, a variety of equipment and vehicles would be operating on the site. Table 2-2 provides a list of the types of equipment and vehicles expected to be involved in each construction phase.

TABLE 2-2 CONSTRUCTION EQUIPMENT BY CONSTRUCTION PHASE

2.2.3 Operation and Maintenance

Operation and Maintenance Activities

After the construction phase, the O&M building(s) would serve the Project's approximately 12 permanent full-time employees, which would include one plant manager, five engineers/technicians, and six security staff. Project facilities would be monitored during operating (daylight) hours, even though the Project facilities would be capable of automatic start up, shutdown, self-diagnosis, and fault detection.

The Project would require the use of a water supply to maintain the facility. The solar panels may be cleaned up to two times per year, if necessary to optimize output. Water would also be used to provide fire protection, maintain vegetation, and serve the up to two O&M buildings. No chemicals would be used during cleaning of the solar panels. It is estimated that operational non-potable water requirements would be approximately up to 345 AF/year (with a significant portion going to dust control), as well as less than one AF/year of groundwater for potable use in the up to two O&M buildings (final use numbers will be further refined pre-construction). The Project would coordinate with Gila Farm Land, LLC (landowner) and the Palo Verde Irrigation District to secure water service and supply during operation.

No heavy equipment would be used during normal operation. O&M vehicles would include trucks (pickup and flatbed), forklifts, and loaders for routine and unscheduled maintenance and water trucks for solar panel washing. Large heavy-haul transport equipment may be brought to the solar facility infrequently for equipment repair or replacement.

Maintenance schedules would be developed to arrange periodic maintenance and equipment replacement in accordance with manufacturer recommendations for the life-term of the Project. Solar panels are warranted for 25 years or longer and are expected to have a life of 30 or more years, with a degradation rate of 0.5% per year. Moving parts, such as motors and tracking module drive equipment, motorized circuit breakers and disconnects, and inverter ventilation equipment, would be serviced on a regular basis, and unscheduled maintenance would be performed as necessary.

The solar facility would be secured 24 hours per day by on-site private security personnel and remote security services with motion-detection cameras.

Fire Safety

Solar arrays and PV modules are fire-resistant, as they are constructed largely out of steel, glass, aluminum, or components housed within steel enclosures. As the tops and sides of the panels are constructed from glass and aluminum, PV modules are not vulnerable to ignition from firebrands from wildland fires. In a wildfire situation, the panels would be rotated and stowed in a panel-up noon time position. The rotation of the tracker rows would be controlled remotely via a wireless local area network. All trackers could be rotated simultaneously in a hazard situation. During construction, standard defensible space requirements would be maintained surrounding any welding or digging operations. Fire safety and suppression measures, such as smoke detectors and extinguishers, would be installed and available at the O&M facilities, per code. Interior access roads within the solar facility would be 12 feet wide, which allows sufficient access for fire trucks.

A Fire Management and Protection Plan and Emergency Action Plan would be prepared in coordination with the Riverside County Fire Department or other emergency response organizations to identify the fire hazards and response scenarios that may be involved with operating the solar facility. This would include information on response to accidents involving downed power lines or accidents involving damage to solar arrays and facilities.

Interconnection with Statewide Grid

Power produced by the Project would be conveyed to the statewide electricity grid via a new 230 kV gen-tie line from the Project facilities to the Colorado River Substation approximately 4.5 miles west of the solar facility. The Project has secured an interconnection queue position sufficient for the size of the Project at the Colorado River Substation and has made the necessary reservation deposits to CAISO.

Decommissioning and Repowering

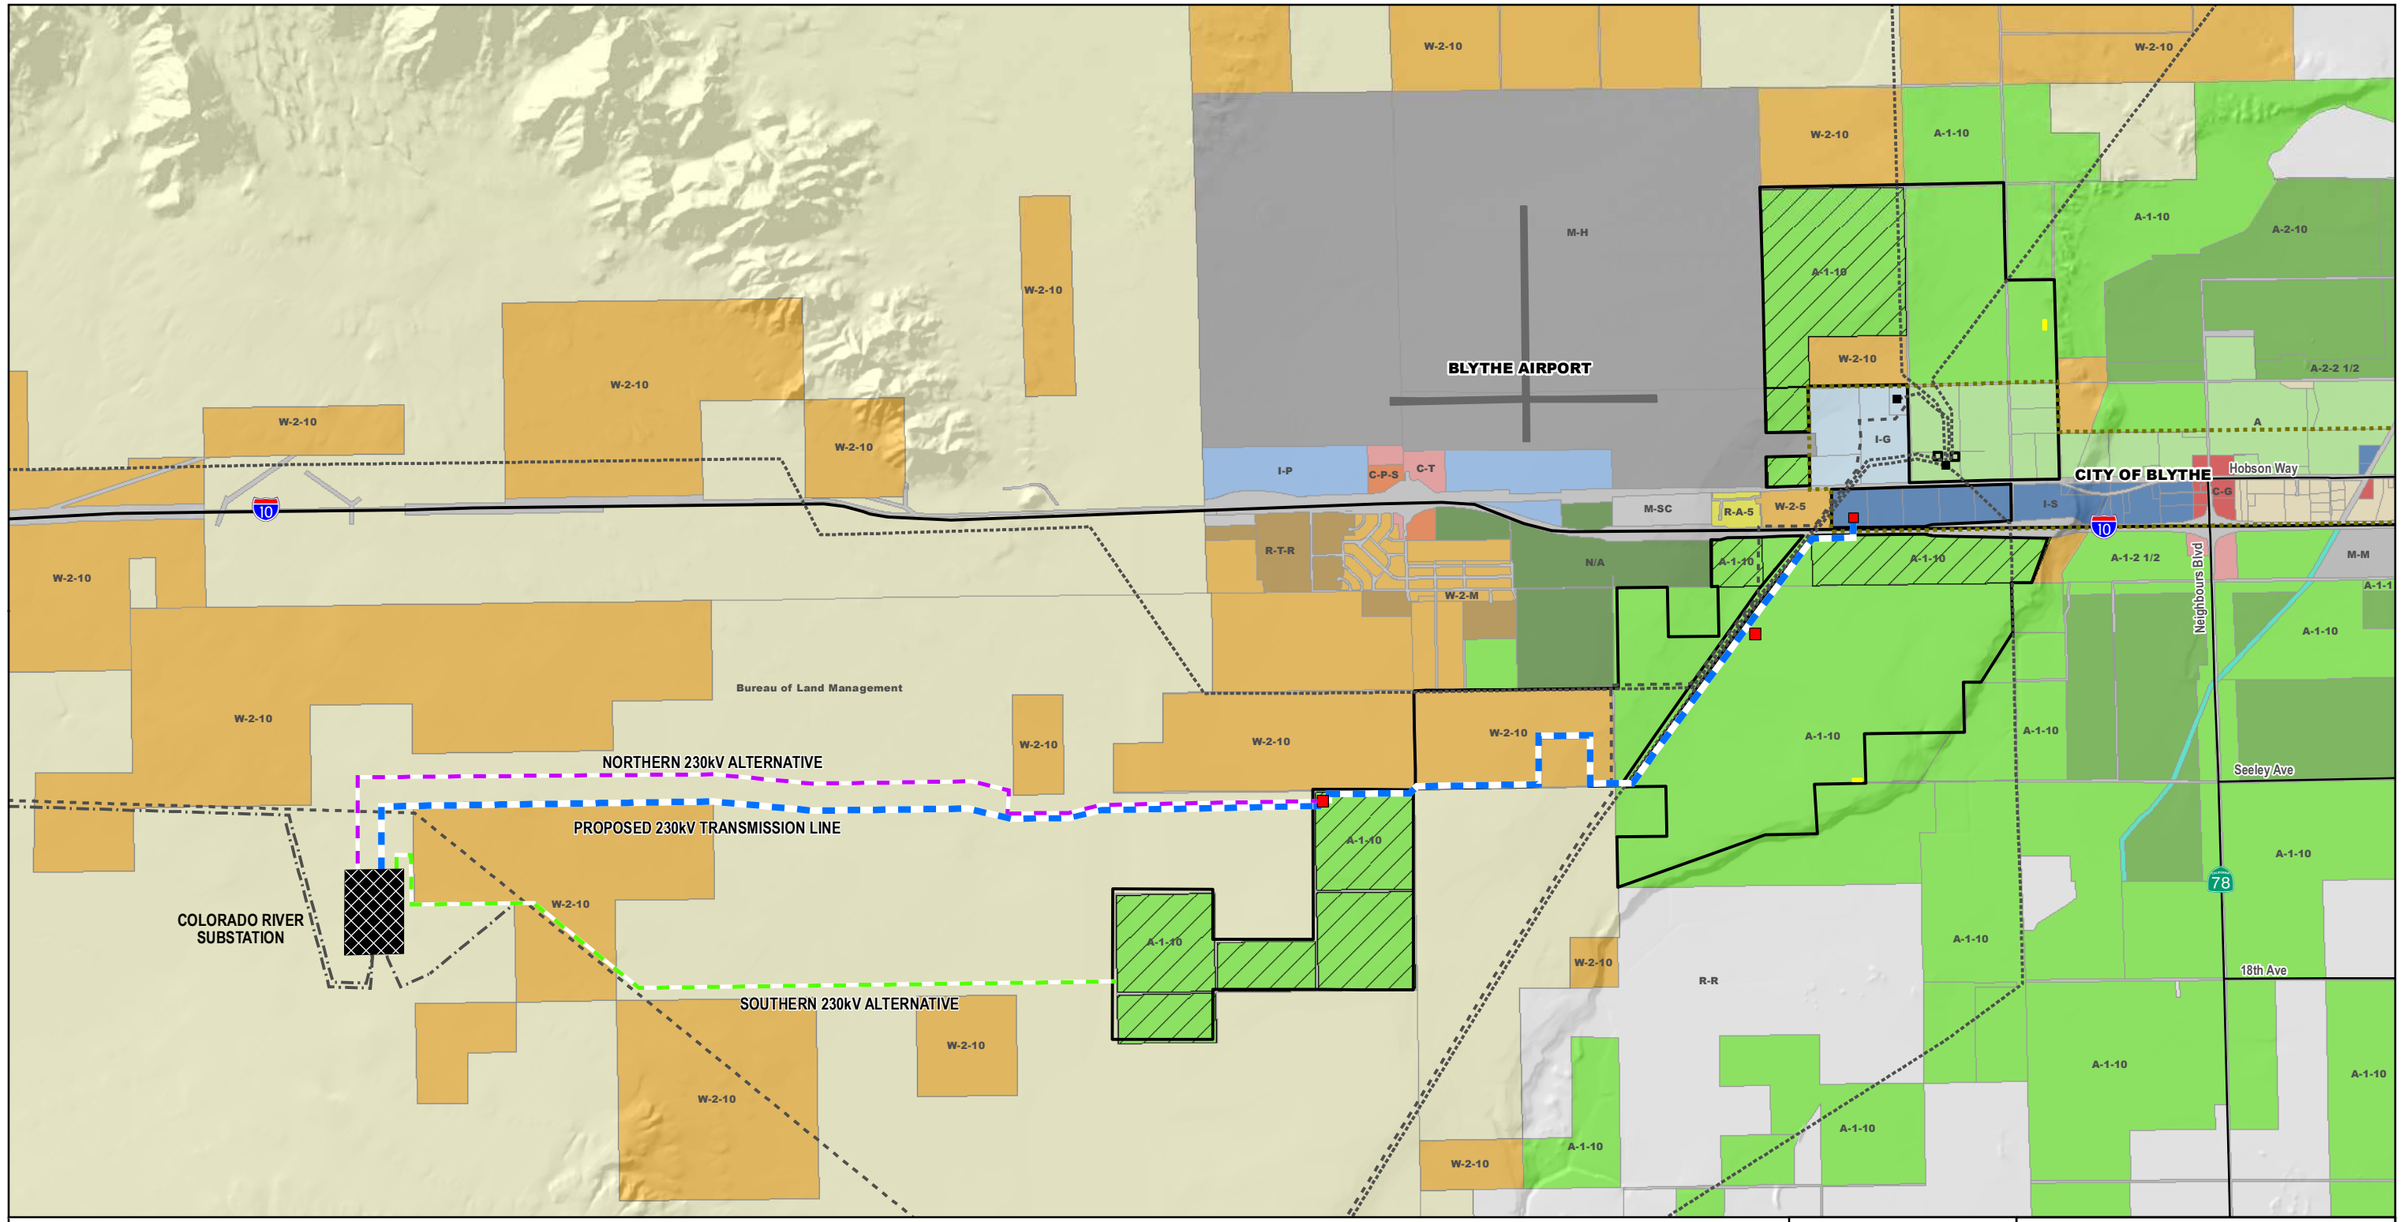
At the end of the energy sales contract term, if the energy buyer is not available for extension or another energy buyer does not emerge, the solar arrays and gen-tie line could be decommissioned and dismantled. Accordingly, this Draft EIR/EA analyzes the impacts of potential decommissioning and dismantling. If the Project continues to operate, the impacts described in this Draft EIR/EA as the impacts of operation and maintenance would continue indefinitely.

Decommissioning activities would require similar equipment and workforce as construction, but would be less intense. The following activities would be involved:

- Dismantling and removal of all above ground equipment (solar panels, track units, transformers, inverters, substations, O&M building(s), switchyard, etc.)
- Excavation and removal of all above-ground cables
- Removal of solar panel posts
- Removal of roads (both gravel and paved, including the aggregate base)
- Break-up and removal of concrete pads and foundations
- Removal of septic system and leach field
- Dismantling of 34.5 kV distribution lines
- Dismantling of 230 kV gen-tie line
- Scarification of compacted areas

The panels could be sold into a secondary solar PV panel market. It is expected that a robust market for used PV panels will exist in the future because the panels can be used in various configurations and at various scales. Electricity demand is expected to continue to rise and electricity prices are projected to continue their steady increase. Demand for solar energy is rapidly accelerating and is expected to grow for decades to come.

The module's component materials lack toxic metals such as mercury, lead, cadmium telluride, or gallium, and the majority of the components of the solar installation are made of materials that can be readily recycled. A Waste Recycling Plan will be developed for the Project, which will identify: materials that will be generated by construction and development; projected amount of materials; measures and methods that will be taken to recycle, reuse, and or reduce the amount of materials; facilities and haulers; and the target recycling or reduction rate. If the panels can no longer be used in a solar array, the silicon can be recovered, the aluminum resold, and the glass recycled. Other components of the solar installation, such as the tracker structures and mechanical assemblies, can be recycled, as they are made from galvanized steel. Equipment such as drive controllers, inverters, transformers, and switchgear can be either reused or their components recycled. The equipment pads are made from concrete, which can be crushed and recycled. Underground conduit and wire can be removed by uncovering trenches and backfilling when done. The electrical wiring is made from copper and/or aluminum and can be reused or recycled, as well. Following decommissioning and dismantling of the solar facility, the Project site would be made available for reversion to agricultural use.



Interim Agricultural-Related Actions

The initial use of the Project site to be permitted under the conditional use permit will be active agricultural production. The Project proposes a unique approach to encouraging continued agricultural use of the site pending construction of the solar plant. The Project proposes (a) to rezone approximately 1,249 acres from W-2-5 (controlled development areas) and N-A to A-1-10 (light Agriculture) (refer to Figure 2-12). This will make zoning on these parcels consistent with the zoning on the rest of the solar facility site (refer to Figure 1-3, *Existing Zoning*, in Chapter 1). Approximately 1,485 acres, all south of I-10 and representing the land not planned to be developed immediately, would be placed in an agricultural preserve and put in a Williamson Act contract (refer to Figure 2-13). These actions are intended to help ensure the continued economic viability of agricultural production until construction of solar facilities. Because these actions would facilitate continued agricultural uses of existing agricultural lands, they would not cause new significant impacts and therefore are not addressed in detail in this Draft EIR/EA. However, as a result of the interim actions, the Project includes potential cancellation of the Williamson Act Contract and agricultural preserve, which is addressed in the Agricultural Resources section of this Draft EIR/EA.

2.2.4 Best Management Practices

For the purposes of this Draft EIR/EA, the Best Management Practices (BMPs) listed in Table 2-3 below would reduce the environmental impacts associated with the proposed Project. Although BMPs lessen potential impacts by avoiding, minimizing, or reducing/eliminating impacts, BMPs are distinguished from mitigation measures in this Draft EIR/EA because BMPs are: 1) requirements of existing policies, practices, and measures required by law, regulation, or local policy; 2) ongoing, regularly occurring practices; and 3) not specific to this proposed Project. In other words, the BMPs identified in this Draft EIR/EA are inherently part of the proposed Project and are not additional mitigation measures proposed as a result of the CEQA significance findings. The BMPs listed are measures that would lessen environmental impacts and are referenced throughout Chapter 4 of this Draft EIR/EA.

THIS PAGE INTENTIONALLY LEFT BLANK

TABLE 2-3 BEST MANAGEMENT PRACTICES

BMP	DESCRIPTION
BMP-1	**Drainage, Erosion, and Sedimentation Control Plan**. As part of the County of Riverside's Conditional Use Permit (CUP) requirements, a Drainage, Erosion, and Sedimentation Control Plan would be developed for the Project. The plan would address the drainage, erosion, and sediment control requirements to support all activities associated with construction, operation, maintenance, and decommissioning of the Project. For example, any stockpiles created would be kept on-site, with an upslope barrier in place to divert runoff. Stockpiles would be sprayed with water, covered with tarpaulins, and/or treated with appropriate dust suppressants, especially in preparation for high wind or storm conditions. Certified weed-free straw bale barriers would be installed to control sediment in runoff water; straw bale barriers would be installed only where sediment-laden water can pond, thus allowing the sediment to settle out. Topsoil from the site would be stripped, stockpiled, and stabilized before excavating earth for facility construction. Topsoil would be segregated and spread on freshly disturbed areas to reduce color contrast and aid rapid revegetation.
BMP-2	**Stormwater Pollution Prevention Plan.** In compliance with requirements of the National Pollutant Discharge Elimination System (NPDES) permit, a Stormwater Pollution Prevention Plan (SWPPP) would be developed and prepared for the Project to ensure that protection of water quality and soil resources is consistent with County and State regulations. The plan would identify site surface water runoff patterns and include measures that prevent excessive and unnatural soil deposition and erosion throughout and downslope of the Project site and Project-related construction areas, and would also include measures for non-stormwater discharge and waste management. The SWPPP would cover all activities associated with the construction of the Project, including clearing, grading, and other ground disturbance such as stockpiling or excavation erosion control. The plan would prevent off-site migration of contaminated stormwater, changes in pre-Project storm hydrographs, or increased soil erosion.
BMP-3	**Fugitive Dust Abatement Plan.** As required by the Mojave Desert Air Quality Management District Rule 403, a Fugitive Dust Abatement Plan would be prepared to address fugitive dust emissions during Project construction, operation, maintenance, and decommissioning. The plan would include measures to minimize fugitive dust emissions from wrecking, excavation, grading, clearing of land, and solid waste disposal operations, and would take every reasonable precaution to prevent visible particulate matter from being deposited upon public roadways as a direct result of operations. During construction, all unpaved roads, disturbed areas (e.g., areas of scraping, excavation, backfilling, grading, and compacting), and loose materials generated during Project construction activities would be watered as frequently as necessary to minimize fugitive dust generation. However, the amount of water will be minimized each time to prevent temporarily ponding water that may occur as a result of the fugitive dust plan. In water-deprived locations, water spraying would be limited to active disturbance areas only, and non-water-based dust control measures would be implemented in areas with intermittent use or use that is not heavy, such as stockpiles or access roads. Alternatively, chemical dust suppressants or durable polymeric soil stabilizers could be used. The dust suppression measures would consider the sensitivity of wildlife to the windborne dispersal of fugitive dust containing dust suppressants and the potential impact on future reclamation.
BMP-4	**Fire Management and Protection Plan.** As required by existing law (Title 8 California Code of Regulations [CCR] Section 3221), a Fire Management and Protection Plan would be developed in consultation with the Riverside County Fire Department to identify potential hazards and accident scenarios that would exist at the facility during construction, operation, maintenance, and decommissioning of the Project. The Plan would include the identification of the following: potential fire hazards and ignition sources; proper handling and storage of potential fire hazards; control of potential ignition sources; persons responsible for equipment and systems maintenance; location of portable fire extinguishers; automatic sprinkler fire suppression system; water-spray fire system; coordination with local fire department; and recordkeeping requirements.

BMP	DESCRIPTION
BMP-5	**Emergency Action Plan.** As required by Title 8 CCR Section 3220, the Project would develop a site-specific operations phase Emergency Action Plan. The operations Emergency Action Plan would address potential emergency situations requiring emergency response and/or planned evacuation. The plan would describe accident scenarios, evacuation routes, alarm systems, points of contact, assembly areas, responsibilities, and other actions to be taken in the event of an emergency. In particular, the plan would describe arrangements with local emergency response agencies.
BMP-6	**Lighting Plan.** A lighting plan would be prepared that documents how lighting will be designed and installed to minimize night-sky impacts during facility construction and operations. Lighting for facilities will not exceed the minimum number of lights and brightness required for safety and security and will not cause excessive reflected glare. Light fixtures will not spill light beyond the Project boundary. Where feasible, vehicle-mounted lights will be used for night maintenance activities. Wherever feasible, consistent with safety and security, lighting will be kept off when not in use. The lighting plan will include a process for promptly addressing complaints about lighting.
BMP-7	**Trash Abatement Plan**. A Trash Abatement Plan shall be developed that focuses on containing trash and food in closed and secure sealable containers, with lids that latch, and removing them periodically to reduce their attractiveness to opportunistic species, such as common ravens, coyotes, and feral dogs, that could serve as predators of native wildlife and special-status animals. The Plan would also establish a regular litter pick-up procedure within and around the perimeter of the Project site, and removal of construction-related trash containers from the Project site when construction is complete.
BMP-8	**Cleanup and Restoration.** Upon completion of construction activities, all unused materials and equipment shall be removed from the Project site. All construction equipment and refuse including, but not limited to, wrapping material, cables, cords, wire, boxes, rope, broken equipment parts, twine, strapping, buckets, and metal or plastic containers shall be removed from the site and disposed of properly after completion of construction. Any unused or leftover hazardous products shall be properly disposed of off-site.
BMP-9	**Hazardous materials.** As required by the Clean Air Act, Section 401 of the Clean Water Act, the Toxic Substance Control Act, and the Hazardous Materials Transportation Act, all vehicles and equipment must be in proper working condition to ensure that there is no potential for fugitive emissions or accidental release of motor oil, fuel, antifreeze, hydraulic fluid, grease, or other hazardous materials. Equipment must be checked for leaks prior to operation and repaired as necessary. Refueling of equipment must take place on existing paved roads, where possible, and not within or adjacent to drainages. Hazardous spills must be cleaned up immediately. Contaminated soil would be disposed of at an approved off-site landfill, and spills reported to the permitting agencies. Service/maintenance vehicles should carry appropriate equipment and materials to isolate and remediate leaks or spills, and an on-site spill containment kit for fueling, maintenance, and construction will be available. Cleaning of construction vehicles at commercial car washes should be considered rather than washing vehicles on the Project site so that dirt, grease, and detergents are treated effectively at existing facilities designed to handle those types of wastes.

BMP	DESCRIPTION
BMP-10	**Integrated Weed Management Plan.** In compliance with the Federal Noxious Weed Act and the Plant Protection Act, a Project-specific integrated weed management plan for the control of noxious weeds and invasive plant species would be prepared. The plan would identify presence, location, and abundance of weed species in the Project area and surrounding area adjacent to the Project, as well as identify suppression and containment measures to prevent the spread of weed species and introduction of weed species. Prevention techniques would include: limiting disturbance areas during construction to the minimum required to perform work; limiting ingress and egress to defined routes; maintaining vehicle wash and inspection stations; and closely monitoring the types of materials brought on-site to minimize the potential for weed introduction. During operations, noxious and invasive weed management will be incorporated as a part of mandatory site training for groundskeepers and maintenance personnel. Training will include weed identification and the impacts on agriculture, wildlife, and fire frequencies. Training will also cover the importance of preventing the spread of noxious weeds and of controlling the proliferation of existing weeds.
BMP-11	**Project structures, gen-tie line, and building surfaces.** Project facilities would be sited to ensure that there is adequate space (i.e., setbacks of no less than 100 feet) between solar facilities and natural washes. These setbacks would preserve and maintain the natural washes' hydrological functions. The color and finish of Project structure and building surfaces that are visible to the public will be designed to ensure minimal visual intrusion, contrast, and glare. Grouped structures will be painted the same color to reduce visual complexity and color contrast. Solar panel backs will be color-treated to reduce visual contrast with the landscape setting. Materials, coatings, or paints having little or no reflectivity will be used wherever possible. The visual color contrast of graveled surfaces will be reduced with approved color treatment practices.
BMP-12	**Gen-tie lines.** Gen-tie line support structures and other facility structures shall be designed to discourage their use by raptors for perching or nesting (e.g., by use of anti-perching devices). This design would also reduce the potential for increased predation of special-status species, such as the desert tortoise. Mechanisms to visually warn birds (permanent markers or bird flight diverters) shall be placed on gen-tie lines at regular intervals to prevent birds from colliding with the lines (APLIC 2006 and USFWS 2010). To the extent practicable, the use of guy wires shall be avoided because they pose a collision hazard for birds and bats. Necessary guy wires shall be clearly marked with bird flight diverters to reduce the probability of collision. Shield wires shall be marked with devices that have been scientifically tested and found to significantly reduce the potential for bird collisions. Gen-tie lines shall utilize non-specular conductors and non-reflective coatings on insulators.
BMP-13	**Ground and surface disturbance.** Construction boundaries would be clearly delineated to minimize areas of ground and surface disturbance. Ground-disturbing activities shall be minimized, especially during the rainy season. To the maximum extent possible, construction-related activities (such as vehicle and foot traffic) would avoid areas with intact biological soil crusts. For cases in which impacts cannot be avoided, soil crusts would be salvaged and restored on the basis of recommendations by the County of Riverside and BLM once construction has been completed. Existing rocks, vegetation, and drainage patterns shall be preserved to the maximum extent possible. No paint or permanent discoloring agents shall be applied to rocks or vegetation (to indicate surveyor construction activity limits or for any other purpose). All stakes and flagging shall be removed from the construction area and disposed of in an approved facility. Where feasible, brush-beating, mowing, or use of protective surface matting rather than removing vegetation shall be employed. Clearing and disturbing of sensitive areas (e.g., steep slopes and natural drainages) and other areas shall be avoided outside the construction zone. Surface disturbance would be minimized by utilizing undulating surface disturbance edges; stripping, salvaging, and replacing topsoil; using contoured grading; controlling erosion; using dust suppression techniques; and restoring exposed soils to their original contour and vegetation.

BMP	DESCRIPTION
BMP-14	**Travel and traffic.** Vehicular traffic on-site shall be confined to existing or designated travel routes and designated work areas. Access to the construction site and staging areas shall be limited to authorized vehicles and only through the designated roads. The extent of habitat disturbance during construction shall be reduced by keeping vehicles on access roads and minimizing foot and vehicle traffic through undisturbed areas. To the extent practical, travel shall be limited to stabilized roads. Road maintenance activities shall avoid blading existing forbs and grasses in ditches and adjacent to roads. Abandoned roads and roads no longer needed shall be subsoiled to increase infiltration and reduce soil compaction, then recontoured and revegetated. Construction traffic shall avoid unpaved surfaces to the extent practical (to reduce the risk of compaction) and reduce speed to lessen fugitive dust emissions. On unpaved or unstabilized surfaces within the construction site, speed limits (e.g., 20 miles per hour [mph]) shall be posted with visible signs and enforced to minimize airborne fugitive dust. Project vehicle speeds shall be limited in areas occupied by special-status animal species. Traffic shall stop to allow wildlife to cross roads. Shuttle vans or carpooling shall be used to reduce the amount of traffic on access roads. Workers shall be trained to comply with the speed limit, use good engineering practices, minimize the drop height of materials, and minimize the number and extent of disturbed areas. The Project developer shall enforce these requirements.
BMP-15	**New access roads and parking lots.** New access roads shall be designed and constructed to the appropriate road design standards, such as those described in BLM Manual 9113 or County standards, whichever is applicable. New access roads shall be designed to follow natural land contours in the Project area and avoid existing desert washes. The specifications and codes developed by the United States Department of Transportation (DOT) and County of Riverside Transportation Department are also to be taken into account. Primary access roads and parking lots shall be surfaced with aggregate that is hard enough that vehicles cannot crush it and thus cause dust or compacted soil conditions. Paving may also be used on access roads and parking lots. Alternatively, chemical dust suppressants or durable polymeric soil stabilizers would be used on these locations.
BMP-16	**Diesel engines.** All diesel engines used in the facility would be fueled only with ultra-low sulfur diesel with a sulfur content of 15 parts per million (ppm) or less. The Project would require use of construction diesel engines with a rating of 50 horsepower (hp) or higher that meet, at a minimum, the Tier 2 California Emission Standards for Off-Road Compression Ignition Engines, as specified in the California Code of Regulations, Title 13, Section 2423(b)(1), unless such engines are not available. Equipment meeting Tier 3 standards shall be used as feasible. If a Tier 2 engine is not available for off-road equipment larger than 100 hp, an engine equipped with retrofit controls to reduce exhaust emissions of nitrogen oxides (NO_x) and diesel particulate matter to no more than Tier 2 levels, may be used; however documentation discussing attempts to utilize Tier 3 vehicles must be provided to the County. Regulatory agencies may determine that use of such devices is not practical when: There is no available retrofit control device verified by either the California Air Resources Board (CARB) or the United States Environmental Protection Agency (EPA) to control engines in question to Tier 2 equivalent emission levels and the retrofitted or Tier 1 engines use the highest level of available control technology. The construction equipment is intended to be on-site for five days or less. It can be demonstrated there is a good faith effort to comply with the recommendation and that compliance is not practical. The idling time of diesel equipment would be limited to no more than 10 minutes, unless idling must be maintained for proper operation (e.g., drilling, hoisting, and trenching).

BMP	DESCRIPTION
BMP-17	**High wind conditions.** In compliance with Mojave Desert Air Quality Management District (MDAQMD) Rule 403 criteria, all soil-disturbing activities and travel on unpaved roads must be suspended during periods of high winds, with the exception of those trips necessary to maintain the facility and prevent property damage. A 25 mph wind speed has been determined on the basis of soil properties identified during site characterization. Monitoring of the wind speed would be required at the site during construction, operation, maintenance, and decommissioning.
BMP-18	**Noise.** The Project would minimize construction- and operation-related noise levels to minimize impacts to wildlife and nearby residents.
BMP-19	**Plants and wildlife.** In compliance with the California Fish and Game Code while on the Project property, workers or visitors would be prohibited from: feeding wildlife; moving live, injured, or dead wildlife off roads, ROWs, or the Project site; bringing domestic pets to the Project site; collecting native plants; and harassing wildlife. Areas where wildlife could hide or be trapped (e.g., open trenches, sheds, pits, uncovered basins, and laydown areas) would be covered. If the trenches or excavations cannot be covered, a ramp that will sufficiently allow wildlife to escape shall be placed into the trench or excavated area, or exclusion fencing (i.e., silt fencing) shall be installed around the trench or excavation to prevent entrapment of wildlife. Open trenched, or other excavations that could entrap wildlife, shall be inspected by the qualified biologists daily and immediately before backfilling. For example, an uncovered pipe that has been placed in a trench should be capped at the end of each workday to prevent animals from entering the pipe. If a special-status species is discovered inside a component, that component must not be moved, or, if necessary, moved only to remove the animal from the path of activity, until the animal has escaped. As open trenches could impede the seasonal movements of large game animals and alter their distribution, they would be backfilled as quickly as possible. Open trenches could also entrap smaller animals; therefore, escape ramps would be installed along open trench segments at distances identified in the applicable land use plan or by the best available information and science. If traffic is being unreasonably delayed by wildlife in roads, personnel would contact the Project biologist, who will take any necessary action. Any vehicle-wildlife collisions would be immediately reported to the Project biologist. Observations of potential wildlife problems, including wildlife mortality, would be immediately reported to the BLM or other appropriate agency authorized officer.
BMP-20	**Waste Recycling Plan**. Prior to issuance of a grading and building permit, a Waste Recycling Plan shall be submitted to the Riverside County Water Management Department for approval. The plan shall identify: materials (i.e., cardboard, concrete, asphalt, wood) that will be generated by construction and development; projected amounts of materials; measures/methods that will be taken to recycle, reuse, and/or reduce the amount of materials; the facilities and/or haulers; and the target recycling or reduction rate. During Project construction, the construction site shall have, at a minimum, two bins: one for waste disposal and the other for recycling of construction and demolition materials. An accurate record keeping system of recycling construction and demolition recyclable materials and solid waste disposal shall also be established.

2.3 Alternatives Analyzed in Detail

2.3.1 CEQA and NEPA Requirements for Alternatives

CEQA and NEPA both require consideration of a reasonable range of alternatives to the proposed Project that have the potential to feasibly attain most of the basic objectives of the Project or meet the federal purpose and need. In addition, CEQA requires the consideration of how to avoid or substantially lessen any of the significant or adverse effects caused by the Project. The CEQA and NEPA requirements for the identification of project alternatives are described below.

CEQA Guidelines (Section 15126.6) state the following:

(a) An EIR [Environmental Impact Report] shall describe a range of reasonable alternatives to the project, which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project, and evaluate the comparative merits of the alternatives.

(b) The discussion of alternatives shall focus on alternatives to the project or its location which are capable of avoiding or substantially lessening any significant effects of the project, even if these alternatives would impede to some degree the attainment of the project objectives, or would be more costly.

(c) The EIR should briefly describe the rationale for selecting the alternatives to be discussed. The EIR should also identify any alternatives that were considered by the lead agency but were rejected as infeasible during the scoping process and briefly explain the reasons underlying the lead agency's determination. Among the factors that may be used to eliminate alternatives from detailed consideration in an EIR are: (i) failure to meet most of the basic project objectives, (ii) infeasibility, or (iii) inability to avoid significant environmental impacts.

(d) The EIR shall include sufficient information about each alternative to allow meaningful evaluation, analysis, and comparison with the proposed project.

(e) The EIR shall include the evaluation of the "No project" alternative.

(f) The alternatives shall be limited to ones that would avoid or substantially lessen any of the significant effects of the project. Of those alternatives, the EIR need examine in detail only the ones that the lead agency determines could feasibly attain most of the basic objectives of the project. The range of feasible alternatives shall be selected and discussed in a manner to foster meaningful public participation and informed decision making.

Under NEPA, a federal agency undertaking a "major Federal action" significantly affecting "the quality of the human environment" must prepare an EIS. 42 United States Code [U.S.C.] § 4332(2)(C). As an initial matter, however, an agency can prepare a less detailed EA to assess the need for an EIS (40 CFR Part 1501.4(b)). Based on the conclusions in the EA, the reviewing agency may determine that in lieu of an EIS, it should issue a finding of no significant impact ("FONSI")." *Id.* § 1501.4(e). The Council on Environmental Quality (CEQ) regulations (40 CFR Part 1508.9(b)) further require that an EA shall include brief discussions of the need for the proposal; of alternatives as required by Section 102(2)(E); of the environmental impacts of the proposed action and alternatives; and a listing of agencies and persons consulted. Additionally, BLM NEPA Handbook H-1790-1 Section 8.3.4.2, *Alternatives in an EA,* provides guidance on developing a range of alternatives to permit a reasoned choice among alternatives that meet the purpose and need for the action.

The federal and State lead agencies identified the alternatives below to be carried forward and analyzed in this Draft EIR/EA. Figure 1-1 illustrates the proposed Project and alternative 230 kV gen-tie line alignments.

To provide for a direct comparison to the Project, each action alternative incorporates the Best Management Practices applicable to the Project, and the interim agricultural-related actions that are

proposed by the Project, resulting in potential Williamson Act Contract and future agricultural preserve and Williamson Act Contract cancellation before construction would occur. Also, each of the action alternatives proposes a similarly condensed construction schedule, to ensure that the most intense level of construction-related impacts is studied.

2.3.2 Alternative 2: No Project/No Action Alternative

The No Project/No Action Alternative must be evaluated under CEQA and NEPA. Under the No Project/No Action Alternative, the construction of a solar generating facility and associated infrastructure would not occur. This alternative discusses existing conditions as well as what would be reasonably expected to occur in the foreseeable future if the Project was not approved and did not take place. The construction of a new gen-tie line and the addition of solar array facilities would not occur. Other transmission lines would likely be constructed in or near the transmission corridor. Current, ongoing operation and maintenance activities associated with the agricultural use of the Project site would continue.

2.3.3 Alternative 3: Northern Alternative 230 kV Gen-tie Line

Similar to Alternative 1 (proposed Project), Alternative 3 would include the interim agricultural-related actions, and the construction, operation, maintenance, and potential decommissioning of an up to 485 MW solar PV electrical generating facility and associated infrastructure. It would occupy a total of 3,665 acres and would utilize the same solar facility site as the proposed Project. The fenced-in solar PV electric generation facility would occupy approximately 3,587 acres on privately-owned land under the jurisdiction of the County, and approximately 334 acres located within the City of Blythe. The primary difference between Alternatives 1 and 3 is the location of the 230 kV gen-tie line that extends outside of the solar facility site to the Colorado River Substation; the same 230 kV gen-tie alignment within the solar facility site would be utilized for both Alternatives 1 and 3. Both Alternatives 1 and 3 would be located within the Riverside East SEZ; however, Alternative 3 would be located to the north and within a 125-foot ROW entirely on BLM-managed lands. Under this alternative, the total length of the 230 kV gen-tie line both on-site and off-site would be 8.8 miles; 3.6 miles would be located on private lands within the solar facility site boundary and 5.2 miles would be located entirely off-site on BLM-managed lands. The BLM portion of the ROW would total 78 acres. Similar to Alternative 1, at the end of the energy sales contract term of Alternative 3, if the utility buyer is not available for extension or another energy buyer does not emerge, the solar arrays and gen-tie line could be decommissioned and dismantled. Following decommissioning and dismantling of the solar facility, the Alternative 3 site would be made available for reversion to agricultural use.

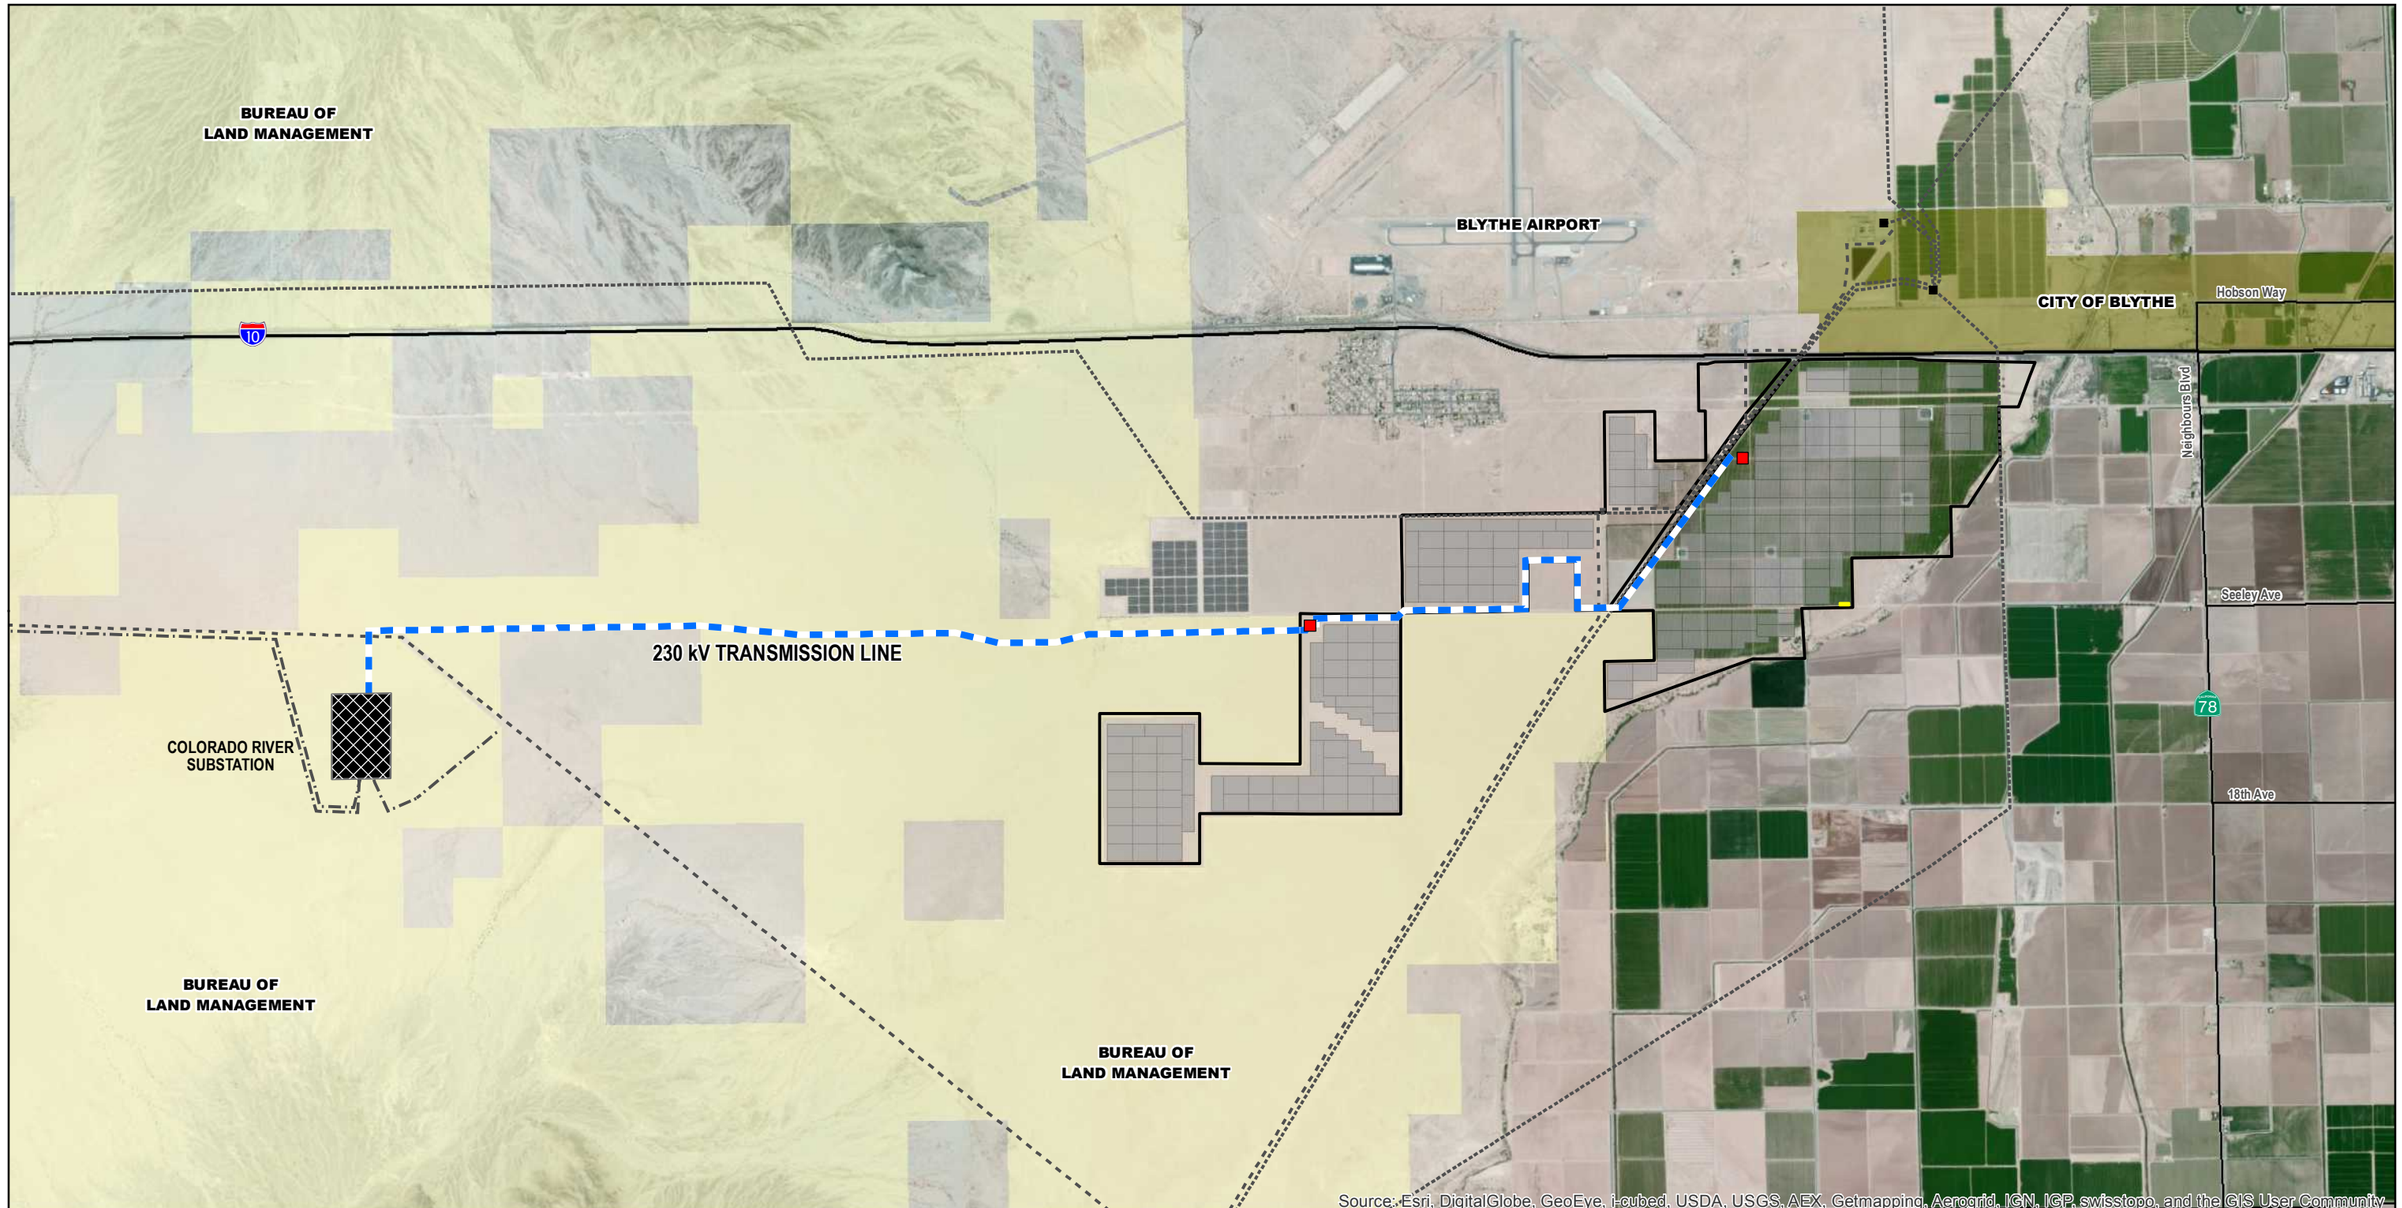
2.3.4 Alternative 4: Southern Alternative 230 kV Gen-tie Line

Also similar to Alternative 1, Alternative 4 would include the interim agricultural-related actions, and the construction, operation, maintenance, and potential decommissioning of an up to 485 MW solar PV electrical generating facility and associated infrastructure. Alternative 4 would occupy a total of 3,647 acres and would utilize the same solar facility site location as the proposed Project. The fenced-in solar PV electric generation facility would occupy approximately 3,587 acres on privately-owned land under the jurisdiction of the County, and approximately 334 acres located within the City of Blythe. The primary difference between Alternatives 1 and 4 is the location of the 230 kV gen-tie line that extends between the solar facility site and the Colorado River Substation. Under Alternative 4, the gen-tie line would exit the southwestern portion of the solar facility site and extend approximately four miles west to the Colorado River Substation within a 125-foot ROW. To facilitate this alignment, an additional 10,000 feet of 230 kV gen-tie line would need to be built on the solar facility site extending south from the proposed substation 3 and angling west to the site boundary. As illustrated on Figure 1-1, Project Area, the gen-tie line would continue westerly off-site across 3.4 miles of BLM-managed lands and 0.6 mile of private lands before reaching the Colorado River Substation. Under this alternative, the total length of the 230 kV gen-tie line both on-site and off-site would be 9.5 miles; 5.5 miles would be located on private lands within the array site boundary and 4.0 miles would be located off-site. The total area of the ROW off-site would be about 60 acres (50 acres of BLM-managed land and 10 acres of private land). Similar to Alternative 1, at the

end of the energy sales contract term of Alternative 4, if the utility buyer is not available for extension or another energy buyer does not emerge, the solar arrays and gen-tie line could be decommissioned and dismantled. Following decommissioning and dismantling of the solar facility, the Alternative 4 site would be made available for reversion to agricultural use.

2.3.5 Alternative 5: Reduced Acreage Alternative

Similar to Alternative 1, Alternative 5 would include the interim agricultural-related actions, and the construction, operation, maintenance, and potential decommissioning of a solar PV electrical generating facility and associated infrastructure; however, Alternative 5 would eliminate development north of I-10 (see Figure 2-14). In comparison to the proposed Project, Alternative 5 would reduce electrical generation from a maximum of 485 MW to a maximum of 315 MW. The alternating current solar PV facility would be located on a footprint of approximately 2,476 acres, reduced from 3,660 acres. The Reduced Acreage Alternative would include approximately 2,403 acres for the solar facility and 73 acres for the 230 kV gen-tie line. Components of the Reduced Acreage Alternative that differ from the proposed Project would include the following:



- **Solar facility site (2,403 total acres)**
  - Up to two on-site substations (each approximately 90,000 square feet)
  - One O&M building (approximately 3,500 square feet)
  - One primary off-site access roads and several interior access roads
- **Approximately 7.8 miles of 230 kV gen-tie transmission line**
  - Approximately three miles would be located within the solar facility, which would connect all on-site substations
  - Approximately 4.8 miles would extend outside of the solar facility and would be placed within a 125-foot-wide ROW and occupy 73 acres

The fenced-in solar PV electric generation facility would occupy approximately 2,403 acres on privately owned land (all within the County of Riverside). Similar to the proposed Project, the portion of the gen-tie line outside the solar facility site, from the southernmost substation to the Colorado River Substation, would traverse 3.8 miles of BLM-managed lands (approximately 58 acres) and approximately one mile of private land (approximately 15 acres). Similar to Alternative 1, at the end of the energy sales contract term of Alternative 5, if the utility buyer is not available for extension or another energy buyer does not emerge, the solar arrays and gen-tie line could be decommissioned and dismantled. Following decommissioning and dismantling of the solar facility, the Alternative 5 site would be made available for reversion to agricultural use.

Reduced Acreage Alternative Project Facilities

230 kV Gen-tie Lines

The Reduced Acreage Alternative would no longer extend a 230 kV overhead gen-tie line from an on-site substation located north of I-10, as this alternative would eliminate all development north of I-10. Therefore, the approximately 8.4-mile-long line associated with the proposed Project would be reduced under this alternative. The Reduced Acreage Alternative would construct an approximately 7.8-mile-long 230 kV overhead gen-tie line from the proposed on-site substation located south of I-10 to the Colorado River Substation, which is currently under construction. Approximately three miles of the gen-tie line would be located within the solar facility. Similar to the proposed Project, the Reduced Acreage Alternative 230 kV gen-tie line would also extend another 4.8 miles within a 125-foot-wide ROW from the southernmost substation to the Colorado River Substation (3.8 miles would traverse BLM-managed

lands and one mile would traverse private land). The gen-tie line would run parallel to and immediately south of the 500 kV Desert Southwest Transmission Line corridor. The gen-tie line poles and foundations associated with the Reduced Acreage Alternative would be identical to those of the proposed Project.

Access Road

Under the Reduced Acreage Alternative, one access point to the solar facility is planned on Seeley Avenue, accessible from the Neighbours Boulevard off-ramp from I-10 (see Figure 2-14). The primary access road would be improved at the entrance to the site for 100 feet and would be 16 to 20 feet wide. Similar to the proposed Project, unpaved access roads within the solar field would be 12 feet wide and constructed approximately every 200 to 400 feet to allow access and maintenance of the solar panels.

Construction

Site Preparation

Site preparation under the Reduced Acreage Alternative would be similar to the proposed Project, only it would exclude the area north of I-10. During Alternative 1 construction, it is anticipated that up to approximately 1,354 AF of water would be utilized for soil moisture conditioning and dust control over the entire construction period (451 AF per year). Under Alternative 5, it is anticipated that water demand will be less, as there would be a reduced solar development footprint and less associated construction. Similar to the proposed Project, Alternative 5 would require minor demolition of existing site structures (e.g., storage buildings in citrus grove, three on-site residences).

Construction Activities

The Reduced Acreage Alternative would be constructed in similar fashion and in the same phases as the proposed Project (simultaneously on different portions of the site), with the difference of one less substation and O&M building.

Construction Sequence, Equipment, and Workforce

Construction for the Reduced Acreage Alternative is anticipated to be similar to the proposed Project; however, under this alternative, construction would require a reduced workforce. The solar field would be developed in six-month phases, with six blocks constructed at a time (each block 100 acres, for a total of 600 acres at a time). Approximately 400 daily workers (compared to 500 under the proposed Project) would be present on-site during peak construction. Workers would gain primary access to the site using Seeley Avenue off of Neighbours Boulevard. Worker construction traffic would consist of approximately 400 daily vehicle roundtrips (240 employees [compared to 300 under the proposed Project] would travel alone, and approximately 160 employees [compared to 200 under the proposed Project] would carpool). Anticipated average daily material deliveries would consist of about 20 truck deliveries per day for 24 months.

TABLE 2-4 DURATION AND NUMBER OF WORKERS OF EACH CONSTRUCTION PHASE: ALTERNATIVE 5

CONSTRUCTION ACTIVITY/PHASE	DURATION	WORKERS
Site Preparation/Clearing/Grading	6 months	15
Staging and Assembly Areas (including access roads)	6 months	15
Construction of Solar Array, Substations, O&M Building	24 months	200-400
Installation of 230 kV Gen-tie Line and Fiber Optic Cable	12 months	30
Testing	3 months	20
Clean up/restoration	1 month	20

*Construction would occur over a three-year period with construction activities occurring simultaneously.

During construction of the Reduced Acreage Alternative, a similar variety of equipment and vehicles as the proposed Project would be operating on the site. Table 2-2 provided a list of the types of equipment and vehicles expected to be involved in each construction phase.

Table 2-5 lists the estimated disturbance that would occur from the proposed Project and Alternatives. The table separates the disturbance by Project component—solar facility site and gen-tie line corridor. The temporary disturbance within the solar facility site would include: the construction of the solar arrays; fencing; on-site substations; O&M building; main access road; distribution line construction areas; gen-tie line pole construction areas, gen-tie maintenance road; pulling and tensioning sites; sleeving and miscellaneous stringing operations; and guard structure. Permanent disturbance, which is assumed for the life of the Project, within the solar facility site would include the solar arrays; fencing; on-site substation; O&M building; distribution line pole foundations; gen-tie line pole foundations, and gen-tie maintenance road. The temporary disturbance for the gen-tie line corridor includes: the gen-tie line construction areas; gen-tie line poles; pulling and tensioning sites; and sleeving and miscellaneous stringing operations. The permanent disturbance for the gen-tie line corridor includes the gen-tie line pole foundations, and access and spur roads. Table 2-6, Alternatives Comparison Summary, lists the total temporary and permanent disturbance from the proposed Project and Alternatives.

Operation

Operation and Maintenance Activities

Implementation of the Reduced Acreage Alternative would result in the same operation and maintenance activities as the proposed Project. After the construction phase, however, the O&M building would serve the Project's approximately seven permanent full-time employees. It is estimated that operational non-potable water requirements would be less than the estimates for the proposed Project, as well as less than one AF/year of groundwater for potable use in the one O&M building.

Interconnection with Statewide Grid

Power produced by the Reduced Acreage Alternative would also be conveyed to the statewide electricity grid via a new 230 kV gen-tie line from the Project facilities to the Colorado River Substation approximately 4.5 miles west of the solar facility.

Decommissioning and Repowering

At the end of the energy sales contract term, if the energy buyer is not available for extension or another energy buyer does not emerge, the solar arrays and gen-tie line could be decommissioned and dismantled under Alternative 5, similar to the proposed Project. Accordingly, this Draft EIR/EA analyzes the impacts of potential decommissioning and dismantling. If the Reduced Acreage Alternative continues to operate, the impacts described in this Draft EIR/EA as the impacts of operation would continue indefinitely. Similar to the proposed Project, decommissioning activities would require similar equipment and workforce as construction, but would be less intense.

TABLE 2-5 DISTURBANCE ESTIMATES

DISTURBANCE DESCRIPTION	DISTURBANCE DIMENSIONS	AVERAGE DISTURBANCE	ALTERNATIVE 1	ALTERNATIVE 3	ALTERNATIVE 4	ALTERNATIVE 5
Solar Facility Site						
1.5 MW solar array (panels, trackers, equipment pad, access roads between solar arrays)	660 ft X 470 ft	7.12 acres/1.5 MW array	310 solar arrays 2,207 acres	310 solar arrays 2,207 acres	310 solar arrays 2,207 acres	210 solar arrays 1,495 acres
perimeter fence/maintenance road	20 ft wide	2.42 acres/mile	34.8 miles 84.2 acres	34.8 miles 84.2 acres	34.8 miles 84.2 acres	21.6 miles 52.3 acres
on-site substations	300 ft X 300 ft each	2.07 acres each	3 substations 6.21 acres	3 substations 6.21 acres	3 substations 6.21 acres	2 substations 4.14 acres

2.4 Alternatives Comparison Summary

The following sections offer a comparison of the potential environmental impacts associated with the five Project Alternatives (the proposed Project three other action Alternatives, and the No Project/No Action Alternative), which are summarized in Table 2-6. The solar facility site and interior components (solar panels, substations, O&M buildings, and 34.5 kV distribution lines) are the same for Alternatives 1, 3, and 4 and would result in the same associated impacts. The distinctions among these alternatives focus on the impacts of distinct gen-tie lines. The analysis also considers a reduced solar facility project, which would rely on the same gen-tie line as in Alternative 1 (proposed Project).

2.4.1 Action Alternative Resource Summary (Alternatives 1, 3, 4, and 5)

Among the action alternatives, the proposed gen-tie line for the Reduced Acreage Alternative (Alternative 5) is the shortest at 7.8 miles and traverses the least amount of BLM-managed lands (approximately 3.8 miles). Alternative 4's gen-tie line is the longest at 9.5 miles. Alternative 5 would occupy the least acreage of the action alternatives: 2,476 acres (1,184 acres less than Alternative 1; 1,189 acres less than Alternative 3; and 1,171 acres less than Alternative 4). Alternative 1, Alternative 3, and Alternative 5's gen-tie lines would parallel approved and existing transmission lines and access roads. The gen-tie line would require a maintenance road; however, because of the flat desert landscape no grading would be required. Trucks would access the gen-tie lines poles by crushing over existing vegetation. Alternative 1 and Alternative 5 would require 4.8 miles of new gen-tie line maintenance roads. Alternative 3 would require 5.2 miles of maintenance roads. Alternative 4's gen-tie line would parallel an existing transmission line for approximately one mile; however, approximately three miles would not parallel existing transmission lines and would require approximately three miles of new access roads.

Alternative 5's total gen-tie line length is the shortest of the action alternatives. Alternative 5 would have marginally less annual air emissions and lower impact to vegetation communities such as areas of disturbed creosote bush scrub, bajada community, irrigated alfalfa, non-irrigated wheat. The remaining direct and indirect impacts to vegetation communities under Alternative 5 would be similar to the proposed Project analyzed under Alternative 1. Alternative 1 and Alternative 5's gen-tie line would cross 22.9 acres of Desert Riparian Woodland Wash, the same as Alternative 3 but more than Alternative 4 (11.4 acres). No records or survey results indicated the presence of State- or federal-listed plants or wildlife on Alternative 1, Alternative 3, or Alternative 5. However, based on recent survey records, the desert tortoise has a high potential to occur on the Alternative 4 gen-tie line corridor.

Action Alternatives 1 and 3, and 5 would have no cultural resources eligible for listing on the National Register of Historic Places (NRHP) or the California Register of Historical Resources (CRHR). Alternative 4 contains two archaeological sites along the gen-tie line that are unevaluated and avoided by Project design. Alternatives 1, 3, and 4 all contain portions of Site 33-018837, the Blythe Army Air Base (BAAB), but the BLM and County agree that the elements of BAAB within the Project area of potential effects (APE) no longer retain integrity and are not themselves eligible to the NRHP or CRHR. As development under Alternative 5 would occur south of I-10, cultural resources found north of I-10, including BAAB, as analyzed under Alternative 1, would be avoided under Alternative 5 construction. None of the gen-tie alternatives contain eligible cultural resources except possibly the Alternative 4 gen-tie line, which contains two unevaluated archaeological sites that would be avoided by Project design.

None of the action Alternatives would use groundwater during construction; rather, they would utilize water provided by the Palo Verde Irrigation District. An ephemeral stream would bisect the solar facility site for Alternative 1, Alternative 3, and Alternative 5 and the gen-tie lines for these Alternatives would also cross one ephemeral stream; an ephemeral stream would bisect Alternative 4 and its gen-tie line would cross one ephemeral stream twice.

TABLE 2-6 ALTERNATIVES COMPARISON SUMMARY

ISSUES OR CONCERNS		ALTERNATIVE 1 PROPOSED ACTION	ALTERNATIVE 2 NO PROJECT/NO ACTION	ALTERNATIVE 3 NORTHERN ALTERNATIVE 230 KV GEN-TIE LINE	ALTERNATIVE 4 SOUTHERN ALTERNATIVE 230 KV GEN-TIE LINE	ALTERNATIVE 5 REDUCED ACREAGE ALTERNATIVE
Total acreage of the solar facility site	*Private*	3,587acres	0	3,587acres	3,587 acres	2,476 acres

THIS PAGE INTENTIONALLY LEFT BLANK

All the action Alternatives would promote General Plan and Area Plan policies favoring solar development. The County and City would continue to promote agricultural uses in conformity with the Agricultural Preservation Policy of the Palo Verde Valley Area Plan and the City of Blythe Open Space Guiding Policies 1 and 9, but the Project and the other action Alternatives would cease agricultural use of the Project Site once construction begins.

2.4.2 No Project/No Action Alternative (Alternative 2)

Under the No Project/No Action Alternative, ongoing activities would continue, but new impacts associated with the implementation of the No Project/No Action Alternative are not anticipated. Relative to Alternatives 1, 3, 4, and 5, all impacts associated with the construction, operation, maintenance, and decommissioning of the Blythe Mesa Solar Project would be avoided. As such, there would be no effects related to greenhouse gas (GHG) emissions beyond those that already occur on the Project site as a result of existing agricultural operations (zero net increase in GHG emissions). However, the beneficial impacts of the proposed Project associated with providing renewable energy in accordance with the State's adopted RPS and President Obama's Climate Action Plan would also not occur under this Alternative. That is, under the No Project Alternative, renewable energy would not be available to offset the use of energy from other sources, including fossil fuels. Consequently, the No Project Alternative would not achieve the GHG reduction associated with the proposed Project, which was estimated to range from 371,116 to 1,061,829 metric tons of carbon dioxide equivalent (CO_2e) per year.

2.5 Alternatives Considered and Eliminated from Further Analysis

CEQA and NEPA require an EIR/EA to consider a reasonable range of alternatives to the Project that have the potential to feasibly attain most of the basic objectives of the Project (see list below) or meet the federal purpose and need. In addition, CEQA requires the consideration of how to avoid or substantially lessen any adverse effects of the proposed Project. The proposed Project has the potential to have significant adverse effects on Agriculture, Biological Resources, Cultural and Paleontological Resources, Geology and Soils, Hydrology and Water Quality, Noise, and Traffic and Transportation, but would be reduced to less than significant levels with implementation of mitigation measures.

The Applicant's objectives for the Project are as follows:

- Construct a solar energy facility in order to help meet State and federal renewable energy standards and goals.
- Assist with GHG reduction objectives to the maximum extent possible.
- Locate the Project facilities as near as possible to electrical transmission facilities with anticipated capacity and reserved CAISO interconnection position.
- Site the Project in an area with excellent solar energy resource, in order to maximize energy productivity from the PV panels.
- To the extent feasible, site the Project on previously disturbed land with compatible topography in a manner that minimizes environmental impacts.
- Use a proven and available solar PV technology to provide cleanly generated electricity at a competitive price for California electric ratepayers.
- Eventual decommissioning of the 485 MW solar PV electrical generating facility and associated infrastructure at the end of the energy sales contract term, if the energy buyer is not available for extension or another energy buyer does not emerge.

Alternatives to the proposed Project were identified through the scoping process, informational public meetings, and preliminary studies. A number of alternatives to the proposed Project were identified. Some of these alternatives did not have the potential to meet most of the Project objectives, to meet the federal purpose and need, or to avoid or minimize adverse environmental effects, or were considered infeasible through additional study and evaluation. The sections below provide a brief description of each alternative, the alternative's ability to meet the screening criteria, and the rationale for elimination of the alternative from full analysis in this Draft EIR/EA. The alternatives considered but eliminated from further analysis included:

- Solar Power Tower Technology
- Distributed Solar Photovoltaic Alternative
- Conservation and Energy Demand Reduction
- Alternative Site on BLM-managed Land
- Palo Verde Valley Floor Alternative

2.5.1 Solar Power Tower Technology

The solar power tower technology uses a flat mirror "heliostat" system that tracks the sun and focuses solar energy on a central receiver at the top of a high tower. The focused energy is used to produce steam and run a center power generator. The transfer fluid is super-heated before being pumped to heat exchangers that transfer the heat to boil water and run a conventional steam turbine to produce electricity. Although concentrated, solar power systems can store heated fluids to deliver electricity even when the sun is not shining. In areas of high solar insolation potential (i.e., desert environments), the land required to develop a concentrated solar energy power tower facility is comparable to that required for a PV project—approximately five acres per MW of installed capacity (NREL 2012).

Project Objectives

A solar power tower system has the potential to meet most of the Project objectives, depending on whether its location is in conformity with guiding principles of local General Plans.

A solar power tower system, if located at least partially on public lands under BLM management, could also meet the BLM's purpose and need.

Feasibility

Concentrated solar power tower systems are typically not compatible with airports (FAA Solar Guide). Blythe Airport's Runway 26 is approximately 2,900 feet from the Project boundary. The proximity of the Project area to the airport could result in significant impacts due to glint and glare caused by heliostats associated with development of a concentrated solar power tower system, which could cause temporary flash blindness to pilots on arrival or departure or to Air Traffic Control Personnel; electromagnetic interference with on- and off-airport radar systems; and thermal plumes emitted in the airport environs by steam turbine generator cooling systems. In addition, approximately 3,300 acres of the solar facility site would be located within the Blythe Airport Influence Area (Airport Compatibility Zones B1, C, D, and E). According to FAA Regulations, Part 77, Section 77.23 (a)(2), objects greater than 200 feet tall from the ground surface, or 200 feet above the elevation of the airport (whichever is higher) that are within three nautical miles (3.45 linear miles) of an airport could be considered an obstruction to aviation activities (refer to Sections 3.2.8 and 4.2.8, *Hazards and Hazardous Materials*, for a detailed discussion regarding the Airport Operations and regulatory information regarding the Riverside County Airport Land Use Compatibility Plan). A concentrated solar power tower which could be up to 750 feet tall and located within the Blythe Airport Influence Area would penetrate the navigable airspace and obstruct aviation activities; therefore, the Solar Power Tower Technology Alternative would be infeasible.

Environmental Advantages

The footprint required for a solar power tower facility would be equivalent to that of a PV solar system; therefore, the impacts relating to land disturbance would be similar to that of the proposed Project.

Environmental Disadvantages

The environmental disadvantages would occur to visual resources, land use, and water supply/quality. The solar power towers are generally taller than a PV system; therefore, it would be seen from greater distances. Solar power tower systems typically use conventional steam plants to generate electricity, which typically consume water for cooling. In arid settings, such as the Palo Verde Mesa, any increase in

water demand would strain available water resources. Solar power tower facilities would also adversely impact the operations at the Blythe Airport and the Airport Land Use Commission compatibility requirements.

Alternative Conclusions

The use of a solar power tower technology appears to have the ability to meet most of the basic Project Objectives and would have similar impacts as the proposed Project with respect to biology, cultural resources, paleontology, and geology. However, use of this technology would result in comparatively greater impacts to the Blythe Airport's operations. This alternative would be more visible than the proposed Project due to the height of the power tower and creation of cooling system vapor plumes, and the alternative would not avoid impacts to agricultural resources. Therefore, a solar power tower system alternative was not considered further.

2.5.2 Distributed Solar Photovoltaic Alternative

There is no single accepted definition of distributed solar technology. The California Energy Commission's (CEC) 2011 *Integrated Energy Policy Report* defines distributed generation resources as "(1) fuels and technologies accepted as renewable for purposes of the Renewables Portfolio Standard; (2) sized up to 20 MW; and (3) located within the low-voltage distribution grid or supplying power directly to a consumer." Distributed solar facilities vary in size from several kilowatts to tens of megawatts but do not require transmission to get to the areas in which the generated power is used.

A distributed solar alternative would consist of PV panels that would absorb solar radiation and convert it directly to electricity. Under this Alternative, the PV panels would be installed on residential, commercial, or industrial building rooftops or in other disturbed areas like parking lots or disturbed areas adjacent to existing structures such as substations. To create a viable alternative to the proposed Project, there would have to be sufficient newly installed panels to generate up to 485 MW of capacity. According to the 2012 CEC renewable energy acreage calculator, it would take approximately 3,464 acres to construct a 485 MW Distributed Solar Photovoltaic Alternative (0.4 MW/acre), nearly the size of the proposed Project.

Rooftop PV systems and parking lot systems exist in small areas throughout California. Larger distributed solar PV installations are becoming more common. Examples of different distributed PV systems are:

- Nellis Air Force Base, Nevada: Over 72,000 solar panels, generating 14 MW of energy, were constructed in 2007 by SunPower Corp. on 140 acres of Nellis Air Force Base land (Whitney 2007). Energy generated is used at the base.
- SCE, Ontario, CA and Redlands, CA: SCE's newest solar PV installations have a combined peak generating capacity of 12.5 MW. The Ontario installations involved four solar stations on 1.8 million square feet of leased warehouse roofs owned by ProLogis. The 32,950 solar PV panels are capable of generating 5.5 MW. In Redlands, SCE built three installations, with 34,600 panels spread over 1.5 million square feet of ProLogis warehouse roofs, which can generate 7 MW of power (allvoices 2011).
- Metrolink Industry Station, City of Industry, CA; Metrolink's Industry Station was outfitted with approximately 8,000 PV solar panels covering 940 parking spaces that is capable of generating two MW (Velasco 2012).
- FedEx, Oakland, CA: The FedEx Express hub at Oakland International Airport has 5,769 solar PV panels installed on 81,000 square feet that produce approximately 904 kW (SunPower 2014).

Project Objectives

A distributed solar technology alternative, if constructed at 485 MW, has the potential to meet some of the Project objectives. However, this solar power would be distributed throughout California and thus not subject to the same local planning policies. The distributed solar technology would not necessarily meet the objective to locate the facility in areas of high solar resource, because the distributed technology

would be located throughout the state. An implemented distributed generation system would not achieve RPS as efficiently, since scattered, individual solar installations are likely to be less efficient in producing energy because they do not enjoy economies of scale and are less likely to be subjected to rigorous, regular maintenance. Additionally, while 485 MW of rooftop solar has the potential to meet some the Project objectives, contributions from all commercially available renewable technologies are needed to meet California's RPS requirements and to achieve the statewide RPS target for 2020. To meet the 33 percent by 2020 RPS target, CEC staff estimates that the state will need renewable generation in the range of 35,000 to 47,000 gigawatt hours in addition to generation expected from existing facilities (CEC 2011). To meet this goal, Governor Brown's Clean Energy Job Plan calls for adding 20,000 MW of new renewable capacity by 2020 (including 8,000 MW of large-scale wind, solar and geothermal and 12,000 MW of distributed generation).

Distributed solar projects would be located on rooftops and ancillary existing facilities. Consequently, few, if any, of such projects would be located on BLM-managed property. A distributed solar technology alternative could not meet the federal purpose and need to consider the ROW application for the Project in a manner that takes account of the BLM's multiple use mandate for BLM-managed land, and takes account of management objectives to take actions that increase the production and transmission of energy in a safe and environmentally sound manner, to approve non-hydropower renewable energy projects on public lands, and to treat development of renewable energy as a priority for the Department of the Interior.

Feasibility

The rate of PV manufacturing and installation is expected to continue to grow very quickly. In 2011, 311 MW of customer-sited solar was installed, a growth of 60 percent from 2010 (CPUC 2013). Through April 2012, 97 MW of new distributed solar was installed through the California Solar Initiative (CPUC 2012). The addition of a further 485 MW to eliminate the need for the proposed Project cannot be guaranteed. This would require an even more aggressive deployment of PV than the California Solar Initiative program currently employs. As discussed in *Renewable Power in California: Status and Issues* (CEC 2011), challenges to an accelerated implementation of distributed solar PV include:

- **Widely varying codes, standards, and fees.** Local governments with jurisdiction over these projects have widely varying codes, standards, and fees that are a challenge for developers trying to meet permitting requirements.
- **Environmental requirements and permitting.** Distributed generation projects must comply with a number of environmental requirements including permits and approvals from multiple local entities like fire departments, building and electric code officials, and local air districts. Many local jurisdictions do not have energy elements in their general plans or zoning ordinances to provide guidance to renewable development, and developers must request general plan amendments and/or rezoning of developable parcels.
- **Interconnection.** Physical interconnection to the local distribution system may be complicated, depending on the electricity infrastructure in each community. Upgrades to the distribution system can require local permits.
- **Integration of distributed generation.** California utilities need to balance maintaining system reliability and dealing with aging distribution infrastructure. There are issues with integration of large amounts of renewable distributed generation into the distribution system, which brings power from substations to consumers. The increasing amounts of distributed PV solar power generated may exceed load at different times of the day and flow backwards into the circuit or substation. The distribution system needs to be modernized and use technologies that easily allow for two-way flow of electricity as well as improved communication technologies.

Environmental Advantages

Installation of 485 MW of distributed solar PV could require approximately the same acreage as the proposed Project; however, distributed solar PV is assumed to be located on already existing structures or disturbed areas, so little to no new ground disturbance would be required, and there would be few associated biological and cultural impacts. This alternative would also avoid impacts to agricultural resources and air quality impacts resulting from construction activities.

Environmental Disadvantages

None of the environmental impacts of the proposed Project would occur with the Distributed Solar Photovoltaic Alternative. However, the individualized nature of the solar panel installations would compare unfavorably to a utility scale solar project in terms of ability to regulate visual impacts, ability to regulate use of materials containing hazardous substances, control over potential decommissioning, dismantling and disposal of solar panels, and the applicability and enforceability of other environmentally protective mitigation measures and laws.

Alternative Conclusions

Although there is potential to achieve 485 MW of distributed solar energy, the limited number of existing facilities makes it unlikely to be feasible or present environmental benefits. The proposed Project would utilize single-axis PV trackers with high efficiency, monocrystalline, silicon solar panels. The panel design minimizes shading, and by grouping trackers close together, the technology requires 20 percent less land than conventional crystalline fixed tilt systems and 60 percent less land than thin film systems. Rooftop systems typically consist of less efficient fixed-tilt systems that may not be oriented optimally towards the sun, meaning that developers would need to obtain more surface area for the Project if constructed on a rooftop instead of on the ground. The transaction costs of obtaining multiple rooftops, the complexity of mobilizing construction crews across multiple projects including the transporting and deployment of construction materials in a less efficient manner, and the need to develop the agreements to secure the same amount of PV-produced electricity can make this type of alternative infeasible.

To the extent that distributed generation projects might have fewer impacts on certain resources because they do not utilize substations and transmission facilities, the discussion here illustrates that distributed generation projects cannot meet one of the fundamental objectives of a utility-scale solar project: to provide renewable energy to utility off-takers and their customers. Rooftop systems that are not connected to the utility side of the electric grid only generate power for on-site consumption. At the same time, the difficulties in supplying a comparable amount of megawatts of clean energy to the public through the utility sector has its own set of impacts due to failure to offset the impacts of counterpart fossil fuel energy sources.

There are a number of challenges associated with the implementation of a distributed solar technology, which include widely varying codes, standards, and fees; environmental requirements and permitting concerns; interconnection of distributed generation; inefficiencies; and integration of distributed generation into the electrical grid. As a result, this technology was eliminated from detailed analysis as an alternative to the proposed Project.

2.5.3 Conservation and Energy Demand Reduction

Conservation and demand reduction consist of a variety of approaches for the reduction of electricity use, including energy efficiency and conservation, building and appliance standards, and load management and fuel substitution.

Project Objectives

The alternative would not meet the objectives of constructing a solar energy facility to meet renewable energy standards and goals. It would assist with GHG reduction objectives. However, this alternative likely would not meet the projected demand for energy. This alternative would not help BLM achieve its management objectives or multiple use mandate.

Feasibility

Energy efficiency in general is feasible and would assist with GHG reduction. However, energy efficiency alone would not meet State and federal renewable energy standards and goals. The CEC's 2011 *Integrated Energy Policy Report* takes energy efficiency and conservation into account when determining the RPS assumptions and goals, and concludes that additional sources of renewable energy are required in addition to implementation of conservation measures.

Environmental Advantages

All impacts of the proposed Project would be avoided.

Environmental Disadvantages

Impacts are unknown. Because this alternative would not meet demands, and if no additional power generation facilities were built, it is likely that demand would remain unsatisfied. It is not possible to predict, reasonably, neither what consequences would result from the unmet demand nor where those consequences would occur.

Alternative Conclusions

This alternative is not technically feasible as a replacement for the proposed Project, because California utilities are required to achieve aggressive energy efficiency goals. Additional energy efficiency beyond that occurring in the baseline condition may be technically possible, but it is speculative to assume that energy efficiency alone would achieve the necessary GHG reduction goals. With population growth and increasing demand for energy, conservation and demand management alone is not sufficient to address all of California's energy needs. Therefore, this alternative would not meet Project objectives pertaining to renewable energy goals.

2.5.4 Alternative Site on BLM-managed Lands

Similar to the proposed Project, an Alternative Site on BLM-managed Lands would involve the construction, operation, maintenance, and decommissioning of a 485 MW solar facility and 230 kV gen-tie line. This alternative would be located within the Developable Areas within the Riverside East Solar Energy Zone (SEZ) that was identified by the BLM and Department of Energy (BLM and DOE 2012). Wilderness areas and areas of critical environmental concern (ACECs) were precluded from solar development. Additionally, to achieve the Project objectives, the Alternative Site on BLM-managed Lands would need to be located approximately 20 miles from the Colorado River Substation. It is also assumed that this alternative would require a BLM ROW grant to allow for the construction and operation of solar facilities within BLM-managed lands.

Project Objectives

The construction and operation of a solar facility on an Alternative Site on BLM-managed Lands has the potential to meet the basic Project Objectives. It also has the potential to meet BLM's purpose and need.

Feasibility

Most of the land that would be located in close proximity to the Colorado River Substation and within the Developable Areas of the Riverside East SEZ are in use or proposed for other solar energy projects (see Figure 4.1-1) or within a mountainous area that is not ideal for solar development. It is very unlikely that there would be enough acreage within BLM's Developable Area of the Riverside East SEZ to support a 485 MW solar facility in close proximity to the Colorado River Substation.

Environmental Advantages

This Alternative would avoid adverse impacts to agricultural resources that would result from the implementation of the proposed Project. An Alternative Site would likely be sited farther away from Palo Verde Valley residents and avoid potential less-than-significant impacts to their views.

Environmental Disadvantages

An Alternative Site on BLM-managed Lands would likely be sited closer to wilderness areas and in areas that are generally more natural in appearance compared to lands in the proposed Project; therefore, this Alternative would increase the visual contrast in the area and impacts to visual resources. Also, most of the BLM-managed lands in these areas are undisturbed and would likely experience more severe impacts to biological and cultural resources than the proposed Project, which is located on previously disturbed land. BLM-managed land would likely require more extensive grading because the land has not been previously disturbed, and construction of more or longer access roadways. These activities are likely to result in greater air quality, biological, and cultural impacts.

Alternative Conclusions

The Alternative Site on BLM-managed Lands would avoid impacts to agricultural resources; however, it may not be feasible to find an Alternative Site on BLM-managed Lands, because most of the land within the Developable Areas of the Riverside East SEZ is in use, proposed for other solar energy projects, or within mountainous areas. This alternative would likely have impacts similar to those of the proposed Project for many resource elements, such as air quality and traffic. However, it is likely to have more severe biological, cultural, and visual resource impacts, as it would likely be located on undisturbed lands. This alternative would also be sited closer to wilderness areas and ACECs, which border the developable SEZ areas. The Alternative Site on BLM-managed Lands would not present significant environmental advantages over the proposed Project.

2.5.5 Palo Verde Valley Floor Alternative

Similar to the proposed Project, the Palo Verde Valley Floor Alternative would involve the construction, operation, maintenance, and decommissioning of a 485 MW solar facility and 230 kV gen-tie line. The solar facility would be situated on private lands within the Palo Verde Valley (between the Palo Verde Mesa to the west and the Colorado River to the east), instead of the Palo Verde Mesa, as well as on BLM-managed lands. It is also assumed that this alternative would require a BLM ROW grant for the 230 kV gen-tie line and CUP approvals to allow for the construction and operation of solar facilities.

Project Objectives

The alternative has the potential to meet the Project objectives of constructing a solar energy facility to meet renewable energy standards and goals, which would assist with GHG reduction objectives. If this Alternative were sited at least partially on BLM-managed lands, it would have the potential to meet the federal purpose and need.

Feasibility

Among the factors that may be taken into account when addressing the feasibility of alternatives (as described in CEQA Guidelines Section 15126.6(f)(l)) are environmental impacts, site suitability, economic viability, availability of infrastructure, general plan inconsistency, regulatory limitations, jurisdictional boundaries, and whether the proponent could reasonably acquire, control, or otherwise have access to the alternative site.

While it would be feasible to construct a solar facility and gen-tie lines on the Palo Verde Valley Floor, the possibility of finding a contiguous area sufficient for siting a 485 MW facility is unlikely. To have the potential to meet most of the Project objectives, an alternative site would need to be of sufficient size to accommodate the 485 MW solar facility. There are no suitable sites that are available or within the control of the Project Applicant. Given the size of the proposed Project, the Project objectives, and the need to arrange a suitable assemblage of parcels, it is impractical and infeasible to propose the Project on an alternative site within Palo Verde Valley Floor and still proceed within a reasonably similar timeframe.

In addition, the Palo Verde Valley Floor contains large areas of land classified as Prime Farmland, Farmland of Statewide Importance, and Unique Farmland. Purchasing and converting these prime farmlands, to nonagricultural use would increase the timeframe, effort, and cost of obtaining site control. This alternative has effects that cannot be reasonably ascertained, and its implementation is speculative. Therefore, an alternative site on the Palo Verde Valley Floor has been eliminated from further consideration because it is not considered to be potentially feasible.

Environmental Advantages

In comparison with the Palo Verde Valley Floor Alternative, the proposed Project would be located on the larger contiguous area of designated Prime Farmland. By contrast, the Palo Verde Valley Floor has a mixture of Prime Farmland, Farmland of Statewide Importance, and Unique Farmland. Impacts to agricultural resources would be transferred from the Palo Verde Mesa to the Palo Verde Valley Floor with implementation of the Palo Verde Valley Floor Alternative, but agricultural impacts would not be reduced.

Environmental Disadvantages

The Palo Verde Valley Floor is one of the richest agricultural regions in California. The soils, deposited by the Colorado River, are classified as Prime Farmland, Farmland of Statewide Importance, and Unique Farmland. The proposed Project is located on the Palo Verde Mesa The Palo Verde Irrigation District is committed to keeping the Palo Verde Valley lands in agriculture and is likely to oppose solar energy development (BrightSource 2011). Maintaining viable agricultural land for future generations is also an important aspect of Riverside County's Palo Verde Valley Area Plan.

The Palo Verde Valley Floor Alternative is also farther away from the Colorado River Substation and would require a longer gen-tie line, which would increase the amount of ground disturbance and potential impacts to aesthetics, air quality, biological resources, cultural resources, hydrology and water quality, and traffic and transportation. This alternative would also be closer to more populated areas than the proposed Project, which would further increase impacts to visual resources. The alternative's proximity to the Colorado River has a potential to increase impacts to migratory birds.

Alternative Conclusions

Similar to the proposed Project, the Palo Verde Valley Floor Alternative would also impact agricultural land. This Alternative would also be farther away from the Colorado River Substation, which would increase ground disturbance and impacts to aesthetics, air quality, biological resources, hydrology and water quality, and traffic and transportation. The proximity to the Colorado River could pose adverse impacts related to migratory birds, water resources, and the risk of flooding, which would not result from implementation of the proposed Project. As a result, this alternative was not analyzed in further detail.

CHAPTER 3: AFFECTED ENVIRONMENT

3.1 Introduction

Chapter 3 describes the affected environment and the existing environmental conditions, or "baseline conditions," associated with the construction, operation, and decommissioning of the Blythe Mesa Solar Project (Project) and Alternatives. The baseline conditions are used for comparison to establish the type and extent of the potential environmental effects of the Project. In the following sections, the environmental setting is described within a defined Project area and a regional vicinity context, with a focus on the particular environmental impacts being discussed. The term "Project area" refers to the proposed 485 megawatt (MW) solar photovoltaic (PV) facility and associated infrastructure (3,587 acres), as well as the proposed 230 kilovolt (kV) transmission line (generation interconnection [gen-tie] line) (73 acres). As discussed in Chapter 2, this Draft Environmental Impact Report/Environmental Assessment (Draft EIR/EA) analyzes four Alternatives—the No Project (Alternative 2) and three action Alternatives (the Northern Alternative, the Southern Alternative and the Reduced Acreage Alternative). The proposed solar facility site would be the same for Alternative 1 (proposed Project), Alternative 3 (Northern Alternative), and Alternative 4 (Southern Alternative). Alternative 5's (Reduced Acreage Alternative) solar facility site would occupy the same area as proposed Project; however, it would only include development south of the Interstate 10 (I-10) freeway, which would occupy 2,476 acres instead of 3,600 acres. The main difference between the Alternative 3 and 4 is the location of the 230 kV gen-tie line corridor that extends outside the solar facility site. The Northern Alternative gen-tie line corridor would occupy 95 acres and the Southern Alternative gen-tie line corridor would occupy 60 acres. The proposed Project (Alternative 1) and Alternative 5's gen-tie line corridor would have the same alignment and occupy 73 acres. The environmental setting and impacts analysis for the proposed Project and Alternatives utilizes a study area approach, which may vary based on the resource being evaluated and the predicted locations of direct and indirect effects of the proposed Project.

This chapter also includes a discussion of the regulatory framework for each of the environmental resource topics that present regulations, plans, goals, policies, and standards that may be applicable to the proposed Project and Alternatives. The following environmental topics are addressed in detail in this Draft EIR/EA:

- 3.2.1 Aesthetics, Visual Resources, and Reflection
- 3.2.2 Agriculture
- 3.2.3 Air Quality
- 3.2.4 Biological Resources
- 3.2.5 Cultural Resources
- 3.2.6 Geology and Soils
- 3.2.7 Greenhouse Gas Emissions
- 3.2.8 Hazards and Hazardous Materials
- 3.2.9 Hydrology and Water Quality
- 3.2.10 Land Use and Planning
- 3.2.11 Noise
- 3.2.12 Paleontological Resources
- 3.2.13 Population, Housing, Public Services, Utilities, and Socioeconomics
- 3.2.14 Recreation
- 3.2.15 Traffic and Transportation

The information and data used to prepare this chapter were obtained from several sources including the City of Blythe General Plan, County of Riverside General Plan, and the California Desert Conservation Area (CDCA) Plan. In addition, information was obtained from various U.S. Department of the Interior, Bureau of Land Management (BLM) planning documents, National Environmental Policy Act (NEPA) documents, California Energy Commission (CEC) documents, research publications prepared by various federal and State agencies, and private sources pertaining to key resource conditions found within the

Project area, Alternatives, and surrounding areas. The discussions in this chapter were also informed by the surveys and studies conducted for the Project, as noted throughout this chapter.

3.2 Regional Setting

The Project would be located in eastern Riverside County, approximately five miles west of the city center of Blythe (refer to Figure 1-2, in Chapter 1); portions of the solar array facility would be within the City of Blythe. The proposed Project and Alternatives are situated on the Palo Verde Mesa, which comprises a series of ancient raised river terraces. The topography is relatively flat and slopes toward the southeast; elevations range from 260 to 400 feet above mean sea level (amsl). The following geographic features are located in proximity to the solar facility site and gen-tie lines: the Big Maria Mountains to the northwest; the McCoy Mountains to the west; the Mule Mountains to the southwest; and the Colorado River to the east. These mountain ranges, which trend northwest to southeast, create a natural barrier between the Colorado River and the greater Colorado Desert.

Land uses in the regional area consist of agricultural fields and groves, residences, Blythe Airport, Blythe Energy Center, Blythe Solar Project (owned by NRG), electrical transmission lines, and commercial businesses. Existing open desert lands consist of creosote bush scrub. The proposed solar arrays would be situated primarily within agricultural land, and the gen-tie line within private, disturbed lands and open public lands.

3.2.1 Aesthetics, Visual Resources, and Reflection

Visual resources are the elements of the landscape that contribute to the aesthetic and/or scenic character and quality of the environment. These elements can be either natural or human-made. This section describes the environmental setting and regulatory framework in regards to aesthetics, visual resources, and reflection for the proposed Project and Alternatives. The visual resources inventory describes the existing landscape character and scenic quality of the Project area, identifies sensitive viewpoints and corridors within the visual resources study area, and describes sensitive views in the Project area.

Methodology

The Project area includes private lands for the solar facility and the gen-tie line that would traverse both BLM and private lands. The methodology used to establish baseline environmental conditions includes the inventory of existing visual conditions (visual setting, scenic quality, sensitive viewpoints, visibility and distance zones, key observation points) and incorporation of BLM's policies and guidelines for managing visual resources.

The assessment of aesthetic resources included a review of the proposed Project development plans, regional and local regulatory guidelines, and current land use data. Existing regional landform, vegetation, and water features were reviewed with aerial photography interpretation. Documentation of existing regional physiography was reviewed to determine broad landscape patterns and regionally significant natural features. Land use was determined to identify potential sensitive viewers, viewpoints, and corridors to be evaluated.

A visual resources study area was developed for the Project based on potential for significant impacts. This was based on the scale of the Project and its visual influence on viewers and the landscape. Solar electrical generating facilities may be visible for long distances due to their large scale and contrast with the landscape, particularly from elevated viewpoints that have open views that may encompass an entire facility. Because the Project would be located on flat agricultural land and potential viewers are located at the same elevation as the Project or at a lower elevation, views of the Project would be generally limited to the edges of the solar facility. Because of the low profile of the solar panels, the flat topography, limited development on the mesa on which the Project would be located, and lack of potentially sensitive viewpoints in the mountain ranges around the desert plain, the study area for the solar facility was defined as a 1.0-mile area around the perimeter of the solar facility. For the 230 kV gen-tie line, a 1.5-mile area on

each side (total of a three-mile-wide study corridor) of the centerline was inventoried for visual setting and sensitive viewpoints. The distance threshold for the gen-tie line was based on previous experience with the assessment of visual impacts on transmission lines and previous studies conducted on the visibility of transmission lines in the landscape (Jones and Jones 1976).

Key observation points (KOPs) were selected from the identified sensitive viewpoints and corridors that are representative of views of the Project that would occur during construction, operation, maintenance and decommissioning. Additional viewpoints, such as the residential areas on the Palo Verde Valley floor, were not selected as KOPs because visibility of the Project would be limited. Several mountain ranges with wilderness areas are located around the edges of the desert plain where the Project would be located. However, they do not contain developed trails, parking/trailheads, or other visitor use facilities. See Section 3.2.14, *Recreation*, for a detailed discussion regarding recreational facilities within the Project vicinity. The closest recreational areas to the Project area are the Palo Verde Municipal Golf Course (approximately three miles away) and Midland Long-Term Visitors Areas (approximately seven miles away). These recreational areas would have very distant views of the site that would be difficult to perceive and, therefore, were not selected as KOPs.

BLM Visual Resource Management System

The BLM's Visual Resource Management (VRM) system, as detailed in the 8400 Series Manuals (BLM 1986, 1986a), was also utilized to assess the Project's aesthetic effects. The BLM must consider the scenic values of BLM-administered public lands before allowing uses that may have negative visual impacts. The BLM's VRM system accomplishes this by inventorying scenic values on BLM lands, establishing VRM objectives, and evaluating proposed activities to determine whether they are compatible with the VRM objectives. VRM classes are assigned based on the management decisions made in Resource Management Plans (RMPs). The applicable RMP for the Project is the CDCA Plan. The CDCA Plan does not contain a visual resource element and has not established VRM Classes. Interim VRM Classifications are typically established when a project is proposed and there are no RMP- or Management Framework Plan-approved VRM Classifications. The portion of the Project's gen-tie line corridor that would traverse BLM lands would be in an area of Interim VRM Class III, which was assigned to the area by the McCoy Solar Energy Project Final Environmental Impact Statement (EIS). The objectives of each VRM classification are as follows:

> **VRM Class I**. The objective is to preserve the existing character of the landscape. This class provides for natural ecological changes; however, it does not preclude very limited management activity. The level of change to the characteristic landscape should be very low and must not attract attention.
>
> **VRM Class II**. The objective is to retain the existing character of the landscape. The level of change to the characteristic landscape should be low. Management activities may be seen but should not attract the attention of the casual observer. Any changes must repeat the basic elements of form, line, color, and texture found in the predominant natural features of the characteristic landscape.
>
> **VRM Class III**. The objective is to partially retain the existing character of the landscape. The level of change to the characteristic landscape should be moderate or lower. Management activities may attract attention but should not dominate the view of the casual observer. Changes should repeat the basic elements found in the predominant natural features of the characteristic landscape.
>
> **VRM Class IV**. The objective is to provide for management activities, which require major modification of the existing character of the landscape. The level of change to the characteristic landscape can be high. These management activities may dominate the view and be the major focus of viewer attention. However, every attempt should be made to minimize the impact of these activities through careful location, minimal disturbance, and repeating the basic elements in the predominant natural features of the characteristic landscape.

Environmental Setting

Existing Visual Setting

The Project would be located in the Colorado Desert in the Great Basin section of the Basin and Range Physiographic Province (Fenneman 1931). The topography of the basin is relatively flat with occasional desert washes and slopes toward the southeast; elevations range from 260 to 400 feet amsl. The steeply rising, barren-sloped McCoy Mountains visually dominate the mesa. The mountain ranges, trending northwest to southeast, create a natural barrier between the Colorado River and the greater Colorado Desert. Developed lands in the Project vicinity include agricultural fields (both active and fallow) and groves, residences, the Blythe Airport, the Blythe Energy Center, the Blythe Solar Project, electrical transmission lines, and commercial businesses. I-10, which is a Riverside County Eligible Scenic Corridor, crosses through the study area in an east-west alignment. Undeveloped lands surrounding the Project include open desert and creosote bush scrub. Views of the surrounding mountains provide the most significant scenic vistas and backdrops in the study area. Areas of similar visual character present within the visual resources study area include the following:

I. Open Desert/Fallow Agriculture: These areas are open, sparsely vegetated landscapes that are not developed or actively cultivated for agriculture. Based on the Biological Report vegetation mapping, approximately 24 percent of the solar facility was previously disturbed by agricultural or military activities and six percent remains undisturbed (POWER 2012). The gen-tie line corridors would traverse open desert land mainly comprising desert scrub habitat and disturbed lands associated with existing infrastructure. Several utility lines and maintenance roads run through or parallel the gen-tie line corridors. Additionally, the visual resources study area has been previously disturbed by off-highway vehicle (OHV) use, trash dumping, and historic use for military training during World War II.

II. Cultivated Agriculture: These areas are vegetated, irrigated agricultural areas that include actively cultivated fields and orchards, as well as non-irrigated wheat fields. Based on the Biological Report vegetation mapping, approximately 70 percent of the solar facility area is actively cultivated agricultural land, which includes drip-irrigated citrus orchards, flood-irrigated alfalfa, non-irrigated winter wheat, and abandoned jojoba orchards (POWER 2012).

III. Development: These areas have a wide variety of architectural styles and development patterns, with secondary structures, such as garages and barns, or occasional commercial operations. Along Hobson Way, to the west and east of the Project boundary, are a number of industrial and commercial businesses.

IV. Blythe Airport: The airport landscape includes the runways, associated structures, and open areas within the airport complex. The Project boundary is approximately 0.5 mile from Blythe Airport's Runway 26.

V. Electrical Facilities: Electrical facilities include power plants, substations, and transmission and distribution lines. The Project area surrounds the Blythe Energy Center, a 507 MW natural gas-fired facility, which includes the Buck Substation. The Blythe Substation is located on the solar facility site, just north of Hobson Way. There are a number of high voltage transmission lines (161 kV and 230 kV) that enter and exit the Buck and Blythe substations, which bisect the proposed solar facility site. The Blythe Solar Project, owned and operated by NRG, is an existing 21 MW utility-scale photovoltaic solar array that is approximately 0.5 mile from the proposed solar facility site and adjacent to the 230 kV gen-tie line. The proposed gen-tie line would be collocated with other existing and proposed transmission lines through private and BLM-managed lands. The portion of the Project gen-tie line that would cross BLM lands would be located within the CDCA's Multiple-Use Class M. Multiple-Use Class M allows energy and utility development (BLM 1980). The gen-tie would also be within or adjacent to BLM's designated Utility Corridor K and Section 368 Federal Energy Corridor 30-52, which overlap, and within the Riverside East Solar Energy Zone (SEZ).

Scenic Quality

Scenic quality is a measure of the visual appeal of an area created by the features of the landscape, including both natural landscape features (landform, vegetation, water, color, adjacent scenery, and scarcity) and man-made features (roads, structures, and agriculture). The scenic quality of the landscape was assessed based on the criteria used in the BLM VRM system's Visual Resource Inventory (VRI) scenic quality rating system, described in BLM Manual H-8410-1, Visual Resource Inventory (BLM 1986). Criteria including distinctiveness, contrast, variety, harmony, and balance are assessed and scenic quality classes A, B, or C are assigned. Scenic quality classes are defined as follows:

> **Class A:** Areas have outstanding diversity or interest; characteristic features of landform, water, and vegetation are distinctive or unique in relation to the surrounding region. These areas contain considerable variety in form, line, color, and texture.
>
> **Class B:** Areas have above-average diversity or interest, providing some variety in form, line, color, and texture. The natural features are not considered rare in the surrounding region but provide adequate visual diversity to be considered valuable.
>
> **Class C:** Areas have minimal diversity or interest; representative natural features have limited variation in form, line, color, or texture in the context of the surrounding region. Discordant cultural modifications (e.g., substations, transmission lines, other cultural modifications) can be highly noticeable, which can reduce the inherent value of the natural setting.

While all lands have scenic value, areas with the most variety and most harmonious composition have the greatest scenic value. The scenic quality of the Project area and the visual resources study area was assessed as being Class C, which is common to the region. The flat desert landscape, with its sparse vegetation cover areas, has a low level of variety and distinctiveness and a limited color palette that is common to the region. Agricultural fields and groves add vibrant greens and some visual variety to the landscape. Cultural modifications in the visual resources study area include existing transmission lines and other electrical facilities, the Blythe Energy Center, the Blythe Solar Project, and the Blythe Airport, as well as residential development and commercial facilities associated with the City of Blythe on the west end of the visual resources study area, which reduce the inherent value of the natural setting.

Sensitive Viewpoints Analysis

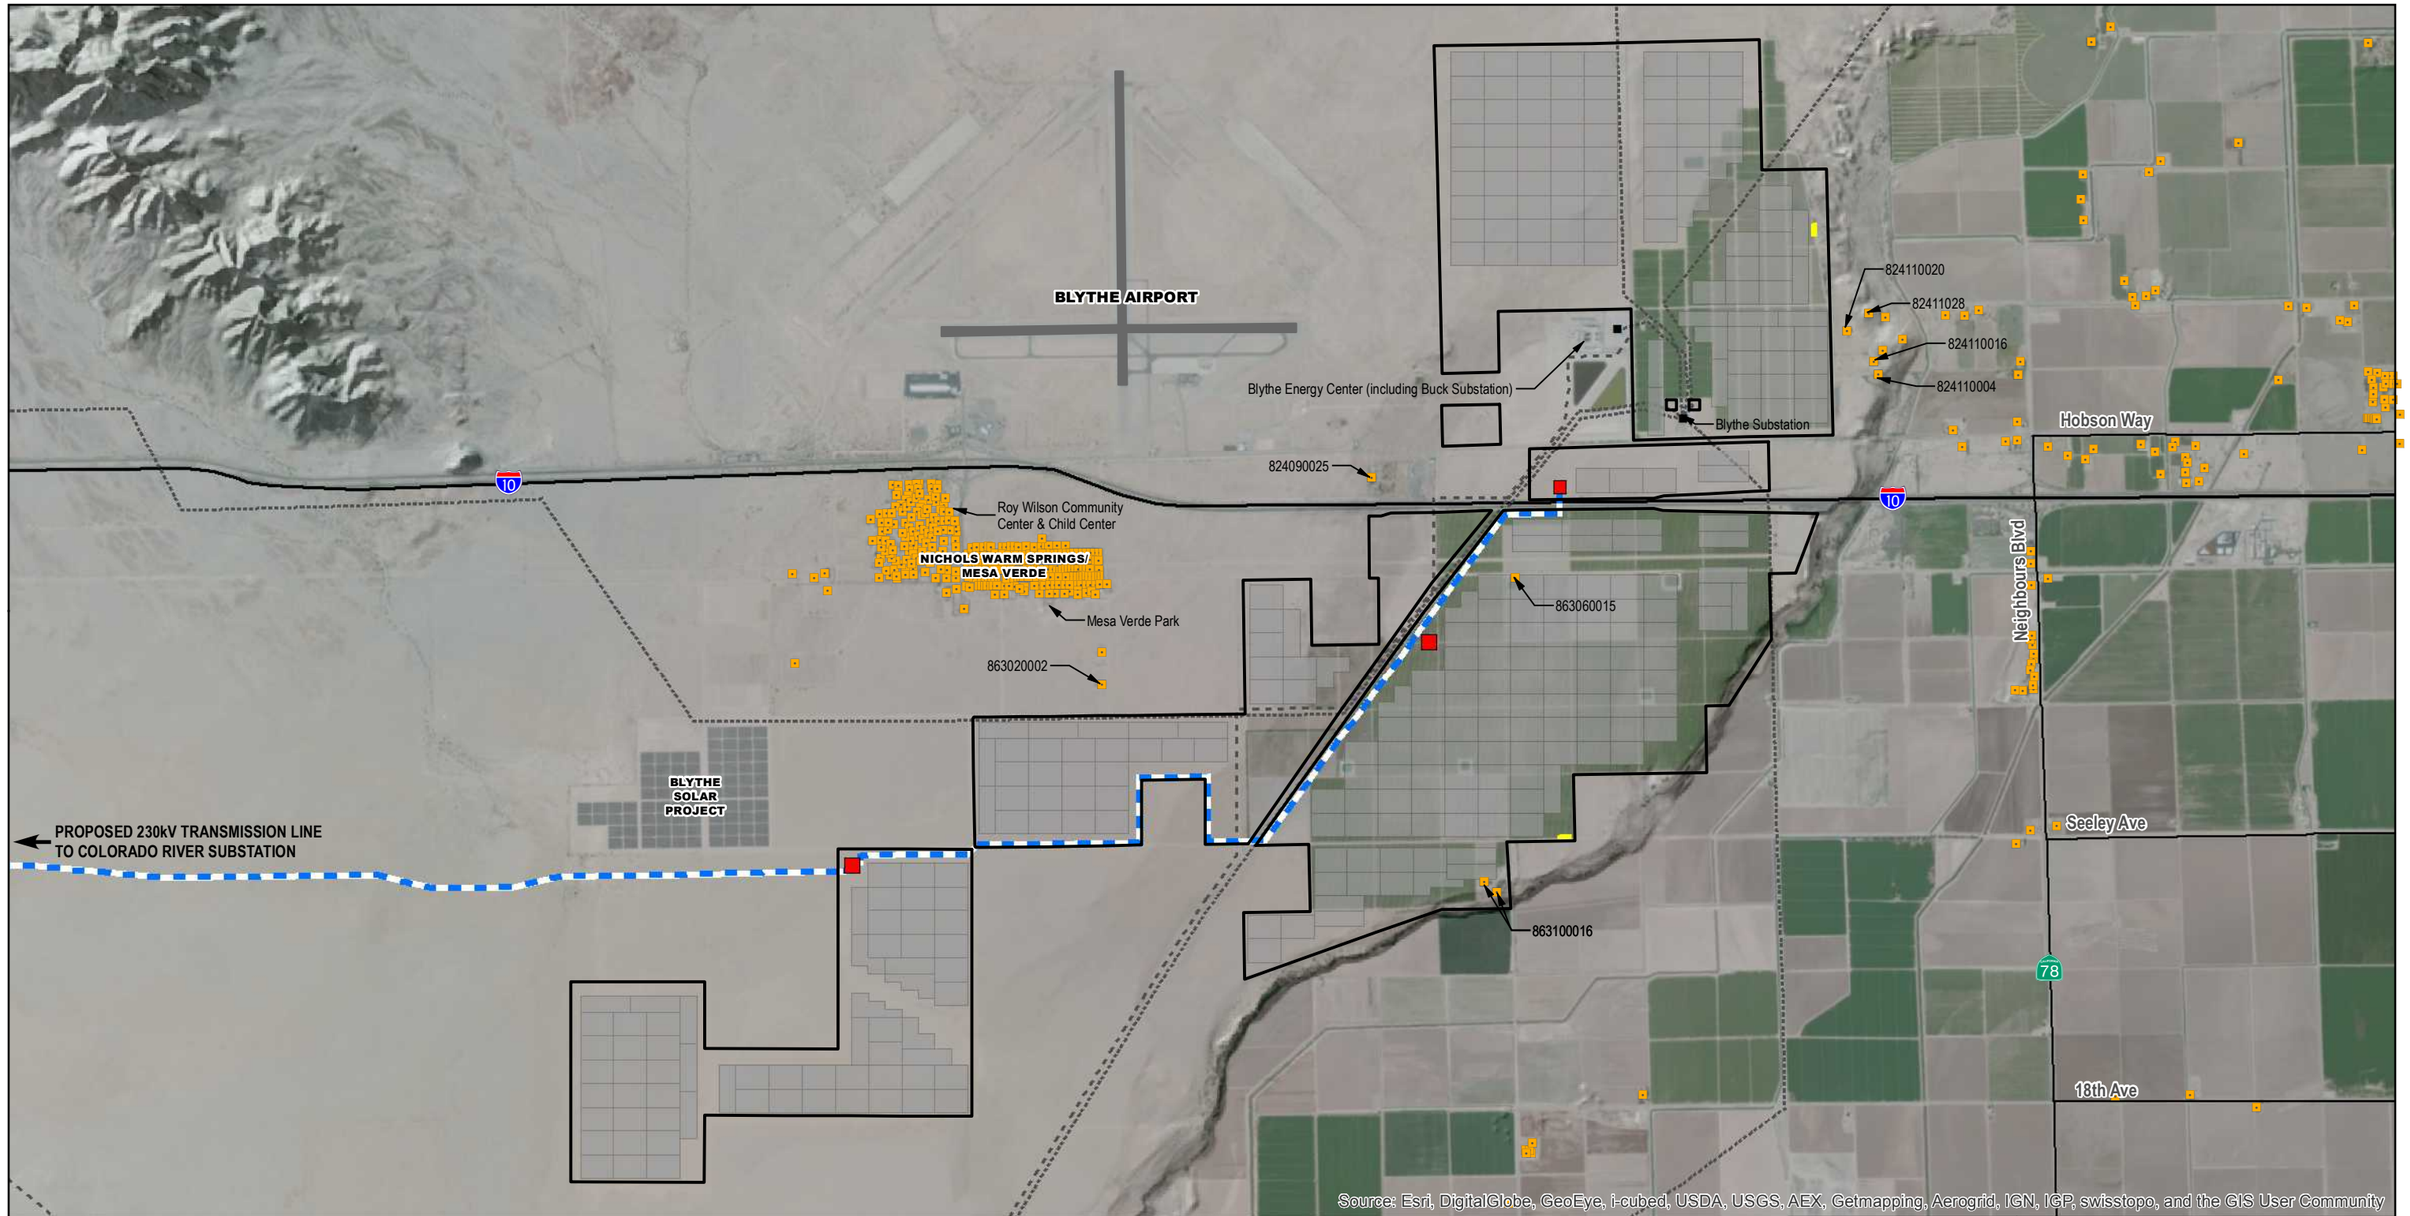
Potentially sensitive viewpoints and corridors within the study area were identified from investigation of agency websites, geographic information system (GIS) shapefiles, aerial photo interpretation, and land use data. Viewpoints and corridors considered include residences, developed recreation areas, and transportation corridors. Viewing context and visual sensitivity level were assessed using the criteria of concern level (expectations for maintaining the existing visual condition), duration of view (static, fixed views or short-duration views), and use volume (number of individual viewers).

Sensitive viewpoints and corridors within the study area that were determined to be highly sensitive to scenery alterations included residences and I-10. Residences generally have a low level of use (relatively few occupants), a high user attitude (high expectations for maintaining existing landscape conditions), and a long duration of view (reoccurring, potentially continuous views). I-10 has a high level of use (many travelers), a high user attitude (expectations for maintaining existing landscape conditions are high because it is a Riverside County Eligible Scenic Corridor), and moderate or intermediate duration views (open highway views).

The Project would be located on the broad and relatively flat Palo Verde Mesa. The majority of residences with views of the solar array are located in the Nicholls Warm Springs/Mesa Verde subdivision south of the Blythe Airport and I-10 (see Figure 3.2.1-1). The residences closest to the Project are located just east of the Project on the mesa. Residences on the Palo Verde Valley floor and outskirts of Blythe are scattered within the eastern half of the visual resources study area. These residences generally do

not have views of the Project due to screening from the 30- to 50-foot bluff that descends to the Palo Verde Valley floor.

Visibility and Distance Zones



Distance zones, or visibility thresholds, for this Project were based on review of distance zones used by the BLM for VRI assessment (BLM 1986) and previous studies in similar geographical, topographical, and environmental settings, and reflect the scale and natural landscape of the objects being viewed. Table 3.2.1-1 provides the visibility thresholds and distance zones used for the Project. Because the components of the solar facility would be much shorter than the 230 kV gen-tie line structures and would become indistinct at a shorter distance, the distance zones for the solar facility are composed of shorter distances than those used for the gen-tie line.

TABLE 3.2.1-1 VISIBILITY THRESHOLDS USED IN VISUAL ANALYSIS

VISIBILITY THRESHOLD	PROJECT COMPONENT	
	Solar Facility	**230 kV Gen-tie Line**
Immediate Foreground	0 to 300 feet	0 to 500 feet
Foreground	300 to 1,500 feet	500 feet to 0.5 mile
Middleground	1,500 feet to 0.5 mile	0.5 mile to 1.5 miles
Background/Seldom Seen	Beyond 0.5 mile	Beyond 1.5 miles

Source: POWER 2012.

Visibility from sensitive viewpoints were generated by GIS using digital terrain data from the U.S. Geological Survey (USGS) and the viewpoints mapped for this study and identified as sensitive (i.e., residences and I-10). Visibility was mapped using ground visibility for the solar facility and a 105-foot uniform height for the centerline of the proposed 230 kV gen-tie line.

THIS PAGE INTENTIONALLY LEFT BLANK

Key Observation Points

The analysis described in this section determined that three KOPs would be sufficient to capture the various types of views of the Project that might be impacted during construction, operation, maintenance, and/or decommissioning. These three KOPs were selected to be representative of the sensitive viewpoints that were identified within the visual resources study area from which the proposed Project would be seen, and were used to evaluate visual impacts.

Photographs were taken at the KOPs with a Canon DSLR Rebel XSI 12-megapixel digital camera fitted with an 18-55 millimeter (mm) zoom lens. The photos were taken with an approximate focal length of 50 mm to represent approximate human viewing conditions. The camera was held at eye-level (approximately five feet from the ground). The date, time of day, global positioning system (GPS) coordinates (latitude/longitude), and weather conditions were documented for each photo location.

The existing visual setting for each KOP is described in the following sections. Figure 3.2.1-2 illustrates the photo locations and views for each KOP's existing condition.

KOP 1: View West from West Riverside Drive

This KOP is located near the residences on the mesa, east of the Project. The view is toward the northwest and encompasses agricultural fields that stretch over the broad, flat landscape of the mesa. See Figure 3.2.1-3 for a photograph of the existing condition. The McCoy Mountains extend across the horizon, with the Big Maria Mountains visible at the northern edge of the view. An existing low voltage distribution line crosses the view in the immediate foreground while additional, higher voltage transmission lines are visible farther away. The Blythe Energy Center is a prominent feature on the southern edge of the view. This view is representative of views from the residences on the mesa and public views along Hobson Way and is a high sensitivity viewpoint. The residences in this area would be the closest residences to the solar facility.

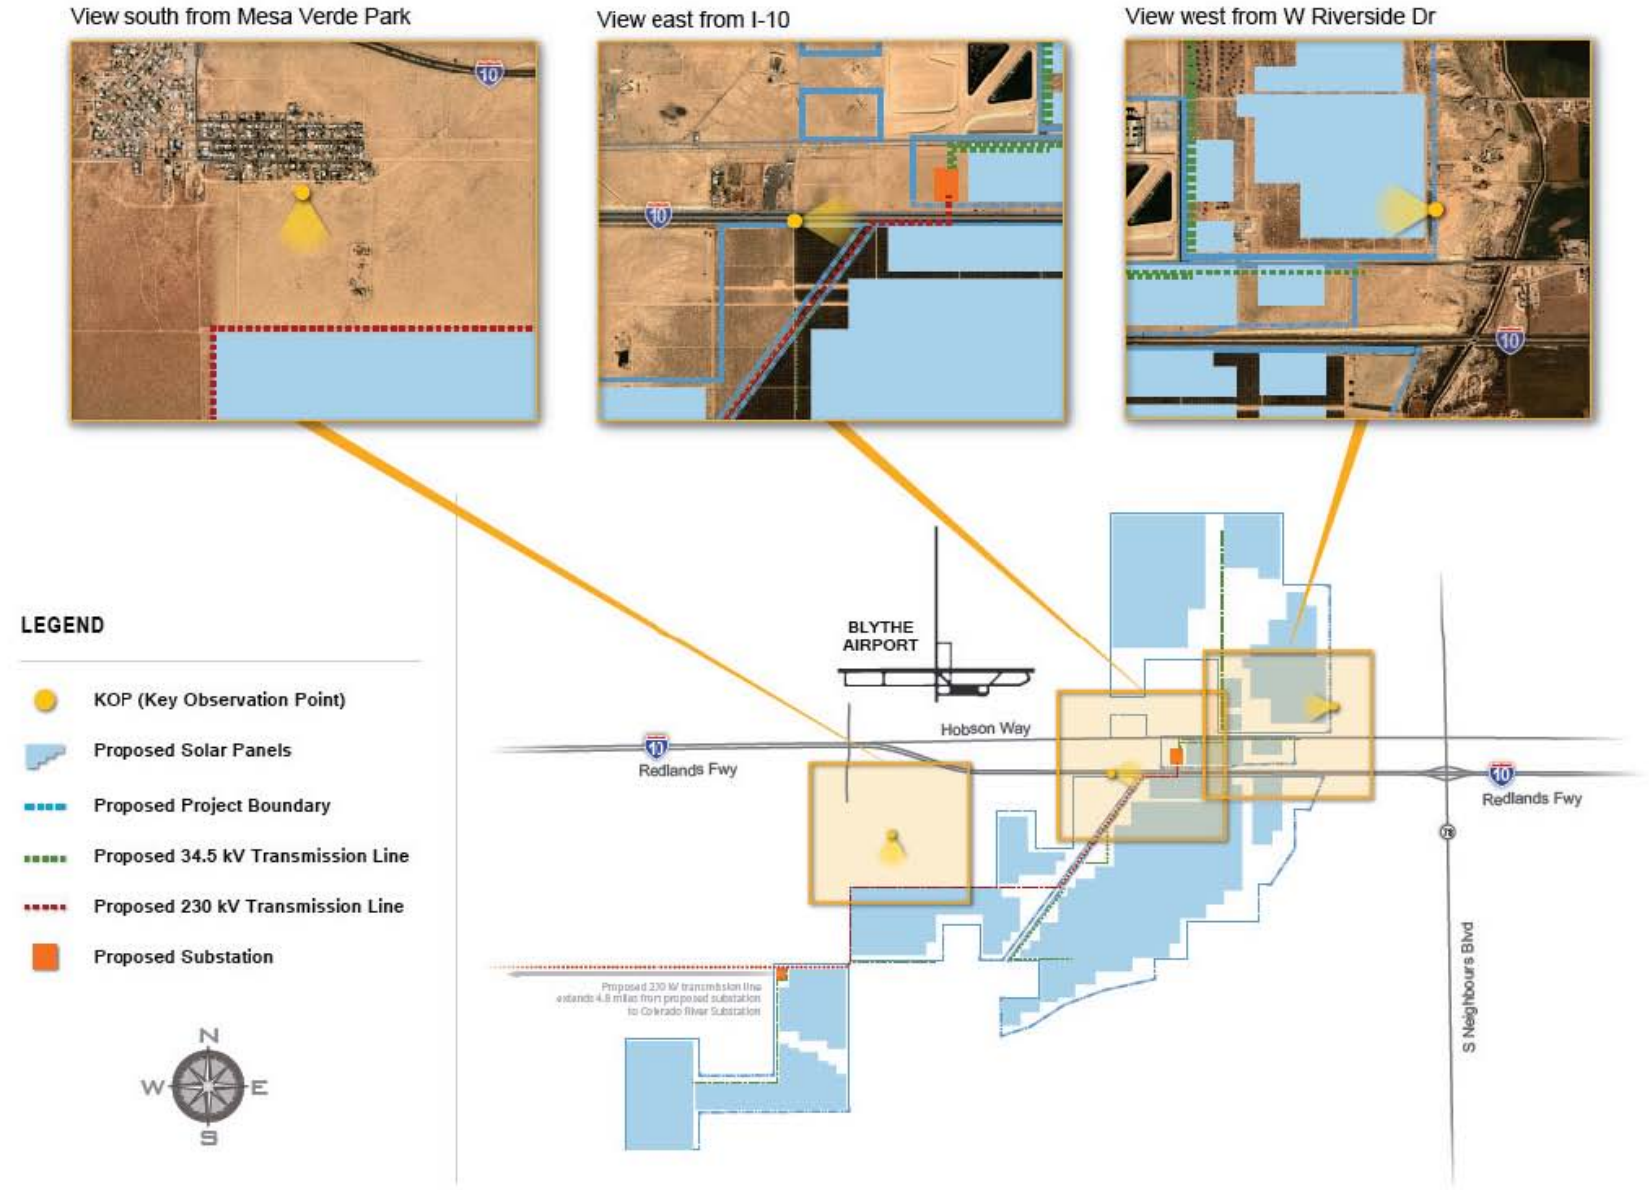

FIGURE 3.2.1-3 EXISTING VIEW FROM KOP 1 (RESIDENCES ON MESA)

THIS PAGE INTENTIONALLY LEFT BLANK

AR062373

FIGURE 3.2.1-2 KOP LOCATIONS AND CAMERA VIEWS

THIS PAGE INTENTIONALLY LEFT BLANK

KOP 2: View from Interstate 10

This KOP is located along I-10, which is a Riverside County Eligible Scenic Corridor and was therefore considered to be a scenic highway. The KOP is representative of views for eastbound and westbound motorists on I-10. See Figure 3.2.1-4 for a photograph of the existing condition.

The photographed view is toward the east and encompasses undeveloped, unvegetated areas and creosote bush scrub, the interstate, several transmission lines, and an agricultural citrus grove. The Sawtooth Mountains are visible on the horizon. Large native shrubs are scattered along the interstate and limit the view on the south side of the roadway.

The view to the west would be similar and would also encompass undeveloped, unvegetated areas and creosote bush scrub, the interstate, and transmission lines. The view to the west would also include the Blythe Airport, the Blythe Energy Center, and the community of Nicholls Warm Springs/Mesa Verde. The Big Maria Mountains to the northwest, the McCoy Mountains to the west, and the Mule Mountains to the southwest provide a backdrop.

FIGURE 3.2.1-4 VIEW FROM KOP 2 (I-10 FREEWAY)

KOP 3: View South from Mesa Verde Park

This KOP is located at a playground on the south end of the community of Nicholls Warm Springs/Mesa Verde. The view is toward the south and encompasses the flat desert landscape of undeveloped, unvegetated areas and creosote bush scrub. An existing transmission line extends across the view. The KOP is representative of views from residences in the Nicholls Warm Springs/Mesa Verde community, which are high-sensitivity viewpoints. See Figure 3.2.1-5 for a photograph of the existing condition.

FIGURE 3.2.1-5 VIEW FROM KOP 3 (NICHOLLS WARM SPRINGS/MESA VERDE)

Palo Verde Valley Residences

Although all residences in the visual resources study are identified as high sensitivity viewpoints, the residences on the Palo Verde Valley floor and outskirts of Blythe were not selected as KOPs because of the limited potential for views of the Project due to topographic screening and distance. However, because some residences may have background views of the Project area, they have been included in the Aesthetics, Visual Resources, and Reflection Affected Environment and Impact Analysis discussions.

Existing Light and Glare

Based on the relatively undeveloped nature of the surrounding landscape, very little light is generated in, or in the vicinity of, the Project area. The primary source of light and glare in the area is motor vehicles traveling on surrounding roadways. During daytime hours, roadways generate glare from the sun's reflection off cars and paved surfaces. Likewise, at night, vehicle headlights on surrounding roadways generate light and glare. Lighting is also located on the Blythe Energy Center site; at the Blythe Airport to alert aircraft of potential hazards in their flight path; and at Palo Verde College.

Regulatory Setting

Federal

BLM VRM System

BLM uses the VRM System to inventory and manage scenic values on lands under its jurisdiction. Guidelines for applying the system are described in the BLM Manual Section 8400 et seq. VRM classes are assigned through RMP). The assignment of VRM classes is based on the management decisions made in RMPs. The applicable RMP for the Project is the CDCA Plan; however, the VRM inventory and management class mapping were not prepared for the CDCA by the BLM and, therefore, VRM Classes

were not established for the proposed Project and Alternatives area. Interim VRM Classifications are typically established when a project is proposed and there are no RMP- or Management Framework Plan-approved VRM Classifications. The portion of the Project gen-tie line that would cross BLM lands would be located within a federally designated Section 368 Energy Corridor (BLM 2009).

Federal Land Policy and Management Act

Section 102(a)(8) of the Federal Land Policy and Management Act of 1976 (FLPMA), 43 United States Code (U.S.C.) § 1701(a)(8), states that "...the public lands [are to] be managed in a manner that will protect the quality of scientific, scenic, historical, ecological, environmental, air and atmospheric, water resource, and archeological values." Section 103(c) of the Act, 43 U.S.C. § 1702(c), identifies "scenic values" as one of the resources for which public land should be managed. Section 201(a), 43 U.S.C. § 1711(a), states that "[t]he Secretary shall prepare and maintain on a continuing basis an inventory of all public lands and their resources and other values (including . . . scenic values)." Section 505(a)(ii) requires that "each right-of-way shall contain terms and conditions which will… minimize damage to scenic and esthetic values." 43 U.S.C. § 1765(a) (ii).

CDCA Plan and the Northern and Eastern Colorado Desert Coordination Management Plan

The Recreation Element of the CDCA Plan specifies that VRM objectives and the contrast rating procedure be used to manage visual resources (BLM 1980). VRM is the process the BLM uses to inventory visual resources (inventory of scenic quality, sensitivity levels, and distance zones), prescribe land use visual standards, and guide Project design to meet the established visual standards. VRM objectives provide the visual management standards for future projects and for rehabilitation of existing projects. Activities within the landscape are designed or evaluated using contrast ratings (BLM 1986).

Local

The Project would be subject to visual policies from the following: Riverside General Plan, the Palo Verde Valley Area Plan, and the City of Blythe General Plan.

Riverside County General Plan

The Riverside County General Plan (adopted October 2003) is applicable to all unincorporated lands within Riverside County. Countywide policies that seek to preserve visual quality are located in the Land Use Element, Open Space Element, and Circulation Element of the County General Plan, and include:

Land Use Element (LU)

Policy LU 6.4. *Retain and enhance the integrity of existing residential, employment, agricultural, and open space areas by protecting them from encroachment of land uses that would result in impacts from noise, noxious fumes, glare, shadowing, and traffic.*

Policy LU 8.1. *Provide for permanent preservation of open space lands that contain important natural resources, hazards, water features, watercourses, and scenic and recreational values.*

Policy LU 13.1. *Preserve and protect outstanding scenic vistas and visual features for the enjoyment of the traveling public.*

Policy LU 13.3. *Ensure that the design and appearance of new landscaping, structures, equipment, signs or grading within Designated and Eligible State and County Scenic Highways corridors are compatible with the surrounding scenic setting or environment.*

Policy LU 13.4. *Maintain at least a 50-foot setback from the edge of the right-of-way for new development adjacent to Designated and Eligible State and County Scenic Highways.*

Policy LU 13.5. *Requires "new or relocated electric or communication distribution lines, which would be visible from Designated and Eligible State and County Scenic Highways, to be placed underground."*

Policy LU 13.8. *Avoid the blocking of public views by solid walls.*

Policy LU 24.8. *Require that industrial development be designed to consider the surroundings and visually enhance, not degrade, the character of the surrounding area.*

Policy LU-25.5. Requires that *"public facilities be designed to consider their surroundings and visually enhance, not degrade the character of the surrounding area."*

Open Space and Circulation Element (OS)

The Public Facilities area plan land use designation provides for the development of private uses with similar characteristics to public uses and includes utility facilities such as public and private electric generating station and corridors. Privately held uses with public facility characteristics are not required to be designated as Public Facilities, but are eligible to be so designated based on site-specific reviews of the characteristics of the use in question.

Policy OS-20.2. Seeks to *"[p]revent unnecessary extension of public facilities, services, and utilities, for urban uses, into Open Space-Conservation designated areas."*

Policy OS-21.1. *Identify and conserve the skylines, view corridors, and outstanding scenic vistas within Riverside County.*

Policy C-19.1. *Preserve scenic routes that have exceptional or unique visual features in accordance with Caltrans'* [the California Department of Transportation's] *Scenic Highways Plan.*

Policy C-25.2. *Locate new and relocated utilities underground when possible. All remaining utilities shall be located or screened in a manner that minimizes their visibility by the public.*

Scenic Corridors

I-10 is not a State- or county-designated scenic highway; however, it has been identified by the County of Riverside in its Circulation Element as eligible for designation as a scenic corridor. The County has indicated in its General Plan Land Use Element that I-10 should be designated a scenic highway and has developed General Plan scenic corridor policies. These policies seek to maintain resources in corridors along scenic highways. Policies for Scenic Corridors include:

- Preserve and protect outstanding scenic vistas and visual features for the enjoyment of the traveling public.
- Incorporate riding, hiking, and bicycle trails and other compatible public recreational facilities within scenic corridors.
- Ensure that the design and appearance of new landscaping, structures, equipment, signs, or grading within Designated and Eligible State and County Scenic Highway corridors are compatible with the surrounding scenic setting or environment.
- Maintain at least a 50-foot setback from the edge of the right-of-way (ROW) for new development adjacent to designated and eligible State and County Scenic Highways.
- Require new or relocated electric or communication distribution lines that would be visible from Designated and Eligible State and County Scenic Highways to be placed underground.
- Prohibit off-site outdoor advertising displays that are visible from Designated and Eligible State and County Scenic Highways.
- Require that the size, height, and type of on-premise signs visible from Designated and Eligible State and County Scenic Highways be the minimum necessary for identification.

The design, materials, color, and location of the signs shall blend with the environment, utilizing natural materials where possible.

- Avoid the blocking of public views by solid walls.

Palo Verde Valley Area Plan

Palo Verde Valley Area Plan (RCTLMA 2008) policies that address visual quality are located in the Local Circulation Policies, Scenic Highways, and include:

PVVAP 10.1. Protect the scenic highways in the Palo Verde Valley planning area from change that would diminish the aesthetic value of adjacent properties in accordance with the Scenic Corridors sections of the General Plan Land Use, Multipurpose Open Space, and Circulation Elements.

PVVAP 10.2. *Encourage the designation of Interstate 10 and US Highway 95 as eligible and subsequently Official Scenic Highways in accordance with the California State Scenic Highway Program.*

City of Blythe General Plan

City policies in the City of Blythe General Plan 2025 (2007) that seek to preserve visual quality are located in the Land Use Element, Open Space Element, Guiding Policies of the City General Plan, and include:

Open Space and Conservation Element

Policy 1: *Maintain hillsides and visible agricultural lands as open space for resource conservation and preservation of views*.

Policy 3: *Maintain existing views of the Mesa and Colorado River from roadways and public uses and other rights-of-way on the valley floor whenever feasible.*

3.2.2 Agriculture

This section describes the environmental setting and regulatory framework in regards to agriculture for the proposed Project and Alternatives. The Project would be located primarily on land zoned for agricultural production. Although timber production is an allowable activity within an agricultural zone, the Project area is not used for timber production, nor is it forested. Because of the arid climate of the area surrounding Project and Alternatives, it is unlikely that the land could support 10 percent native tree cover under natural (i.e., non-irrigated) conditions; therefore, the Project does not meet the definition of “forest land” (Public Resources Code [PRC] Section 12220(g)). The same land is not considered timberland (PRC Section 4526) because the land is not zoned Timberland Production Zone (PRC Section 51104(g)).

The information contained in this section is based on the following resources: Riverside County General Plan; soil classifications by the United States Department of Agriculture’s (USDA) Natural Resources Conservation Service’s (NRCS) Web Soil Survey; California Department of Conservation (DOC) Farmland Monitoring and Mapping Program (FMMP) data; Palo Verde Irrigation District Crop Report; aerial photography; and a study prepared by URS for the Project, applying the Land Evaluation Site Assessment methodology.

The California DOC FMMP produces Important Farmland Maps that document resource quality and land use information. The USDA soil survey information and the corresponding Important Farmland candidacy recommendations are used for assessing local land. The FMMP is intended to assist decision-makers in assessing present status, reviewing trends, and planning for the future of California’s agricultural land resources. The FMMP uses eight land classifications, described below.

Prime Farmland: Farmland with the best combination of physical and chemical features able to sustain long-term agricultural production. This land has the soil quality, growing season, and moisture supply

needed to produce sustained high yields. Land must have been used for irrigated agricultural production at some time during the four years prior to the mapping date.

Farmland of Statewide Importance: Farmland similar to Prime Farmland but with minor shortcomings, such as greater slopes or less ability to store soil moisture. Land must have been used for irrigated agricultural production at some time during the four years prior to the mapping date.

Unique Farmland: Farmland of lesser-quality soils used for the production of the state's leading agricultural crops. This land is usually irrigated, but may include non-irrigated orchards or vineyards, as found in some climatic zones in California. Land must have been cropped at some time during the four years prior to the mapping date.

Farmland of Local Importance: Land of importance to the local agricultural economy as determined by each county's board of supervisors and a local advisory committee. Farmland of Local Importance in Riverside County is defined as:

- Lands with soils that would be classified as Prime or Statewide Important Farmlands but lack available irrigation water.
- Lands planted in 1980 or 1981 in dry land grain crops such as barley, oats, and wheat.
- Lands producing major crops for Riverside County that are not listed as Unique Farmland crops. Such crops are permanent pasture (irrigated), summer squash, okra, eggplant, radishes, and watermelon.
- Dairylands, including corrals, pasture, milking facilities, and hay and manure storage areas, if accompanied with permanent pasture or hayland of 10 acres or more.
- Lands identified by the County with Agriculture land use designations or contracts.
- Lands planted with jojoba that are under cultivation and are of producing age.

Grazing Land. Land on which the existing vegetation is suited to the grazing of livestock. This category was developed in cooperation with the California Cattlemen's Association, University of California Cooperative Extension, and other groups interested in the extent of grazing activities.

Urban and Built-up Land. Land occupied by structures with a building density of at least one unit to 1.5 acres, or approximately six structures to a 10-acre parcel. This land is used for residential, industrial, commercial, construction, institutional, public administration, railroad and other transportation yards, cemeteries, airports, golf courses, sanitary landfills, sewage treatment, water control structures, and other developed purposes.

Other Land. Land not included in any other mapping category. Common examples include low density rural developments; brush, timber, wetland, and riparian areas not suitable for livestock grazing; confined livestock, poultry or aquaculture facilities; strip mines and borrow pits; and water bodies smaller than forty acres. Vacant and non-agricultural land surrounded on all sides by urban development and greater than 40 acres is mapped as Other Land.

Land Committed to Nonagricultural Use. Land Committed to Nonagricultural Use is land that is permanently committed by local elected officials to nonagricultural development by virtue of decisions which cannot be reversed simply by a majority vote of a city council or county board of supervisors.

Environmental Setting

Riverside County

Agriculture remains a strong component in Riverside County's economy, and Riverside County agriculture competes successfully in the global agricultural market. According to the annual Riverside County Agricultural Production Report (2011), agriculture production accounted for an estimated $1,282,256,116 in 2011. The primary agricultural products from Riverside County include nursery stock, milk, table grapes, hay, bell peppers, and eggs. Nursery stock ranked as the top-valued crop in Riverside County.

The most recent agricultural land conversion data available for Riverside County is for the 2008 to 2010 period. Land converted in this period is shown below in Table 3.2.2-1.

TABLE 3.2.2-1 RIVERSIDE COUNTY AGRICULTURAL LAND CONVERSION 2008 TO 2010

LAND USE CATEGORY	TOTAL ACRES INVENTORIED		2008 TO 2010 ACREAGE CHANGES		
	2008	2010	Acres Lost (-)	Acres Gained (+)	Net Acreage Changed
Prime Farmland	122,935	119,635	5,655	2,355	-3,300
Farmland of Statewide Importance	44,653	44,086	1,463	896	-567
Unique Farmland	37,133	35,391	2,780	1,038	-1,742
Farmland of Local Importance	229,156	229,877	7,012	7,733	721
Grazing Land	111,219	110,841	410	32	-378
Agricultural Land Subtotal	**545,096**	**539,830**	**17,320**	**12,054**	**-5,266**

Source: California DOC 2010b.

For the two-year period from 2008 to 2010, Riverside County had a decrease of 5,266 acres in the total amount of active agricultural land mapped by the FMMP. (For comparison, during the 2006 to 2008 period, Riverside County had a net decrease in irrigated farmland of approximately 11,173 acres.) This included a decrease of 4,888 acres of Important Farmland (including Prime Farmland, Farmland of Statewide Importance, Unique Farmland, and Farmland of Local Importance) and a decrease of 378 acres of Grazing Land. The largest decrease was in Prime Farmland, with 3,300 acres converted to non-agricultural uses. There were also decreases in Farmland of Statewide Importance (a net decrease of 567 acres) and Unique Farmland (a net decrease of 1,742 acres) during the 2008 to 2010 period.

Site Description and Vicinity

Palo Verde Valley

The Project would be located on the Palo Verde Mesa, which is west of the Palo Verde Valley area, and a small portion of the solar facility would be within the City of Blythe. The Palo Verde Valley floor is one of the richest agricultural regions in California. The soils, deposited by the Colorado River, are classified as Prime Farmland, Farmland of Statewide Importance, and Unique Farmland, some of which are under Williamson Act contracts. Based on Sheet 3 of the Riverside County Important Farmland 2010 map, approximately 198,000 acres of Important Farmland are within the Palo Verde Valley. The Palo Verde Valley supports agricultural lands that include alfalfa; cotton: wheat and barley; and Sudan grass and Bermuda grass (Barrows 2007). With its long, hot growing season, the Palo Verde Valley is ideal for agriculture; crops are grown and harvested year-round. Mild winters, with a minimum of frost, permit growing of many crops not suitable for production in other areas. Primary agricultural uses in the City of Blythe include alfalfa, cotton, hay, orchards, and field crops. Land to the north and south of I-10 and east of the Mesa are considered suitable for seasonal livestock (sheep) grazing (City of Blythe 2007).

Colorado River water is supplied through the Palo Verde Irrigation District (PVID) canals and laterals. There are also a number of irrigation ditches that are owned and operated by the water users in the PVID. The PVID contains approximately 131,298 acres, 26,798 acres of which are on the Palo Verde Mesa (PVID 2011). Table 3.2.2-2 details the field crops grown in the entire PVID.

TABLE 3.2.2-2 PALO VERDE IRRIGATION DISTRICT CROP REPORT 2011

Source: PVID 2011.

Palo Verde Mesa

The proposed Project is located on the Palo Verde Mesa, generally west of the Palo Verde Valley. Palo Verde Mesa has a higher elevation in comparison to the Palo Verde Valley. Water supplied from the PVID is lifted onto the Mesa by private pumps to irrigate agricultural lands. The PVID provides water to approximately 26,798 acres on the Palo Verde Mesa (PVID 2011).

According to the 2010 FMMP, the solar facility site would occupy 1,707 acres of Important Farmland (1,681 acres of Prime Farmland, 16 acres of Unique Farmland, and 10 acres of Farmland of Statewide Importance) and 1,880 acres of Farmland of Local Importance designated by Riverside County on Palo Verde Mesa. No Williamson Act contract lands are currently located within the Project boundary. Figure 3.2.2-1 illustrates the Important Farmland Classifications in the Project area and includes a 0.25-mile buffer around the solar facility site. The portion of the proposed 230 kV gen-tie line corridor that extends outside the solar facility site is also located on Palo Verde Mesa; however, it does not contain designated agricultural resources.

The predominant crop on Palo Verde Mesa is citrus (refer to the *Biological Resources Technical Report* in Appendix C1). Approximately 24 percent of the solar facility site was previously disturbed by agricultural or military activities. Based on biological vegetation mapping (Table 3.2.4-1), approximately 75 percent of the proposed solar facility site is actively cultivated agricultural land, which includes:

- Drip-irrigated citrus orchards (1,188.4 acres)
- Flood-irrigated alfalfa (404 acres)
- Non-irrigated winter wheat (1,088.2 acres)

The USDA survey identified 15 soil types on the solar facility site (see Figure 3.2.2-2). These include: Aco gravelly loamy sand; Aco sandy loam; badland; Carrizo gravelly sand; Cibola silty clay loam; duneland; Imperial silty clay; Meloland fine sandy loam; Orita fine sand; Orita gravelly fine sandy loam; Ripley very fine sandy loam; Rositas fine sand 0 to 2 percent slopes and 2 to 9 percent slopes; Rositas fine sand, wet, 0 to 2 percent slopes; and Rositas gravelly loamy sand, 0 to 2 percent slopes.

Within an area that includes the solar facility site and a surrounding 0.25-mile buffer of the solar facility site, most of the lands used for agricultural production are located in the Palo Verde Valley to the east and south. Approximately 7,377 acres are within this area, 1,951 acres of which are in agricultural production (URS 2012). Parcels intersected by the line comprising the outside edge of the 0.25-mile buffer are accounted for in their entirety in the acreage calculations. There are 282.2 acres of Williamson Act contracted lands are within this area (URS 2012).

In the 1970s, large-scale development of irrigated agricultural production was attempted on the Palo Verde Mesa. Groundwater supplies were utilized as the primary water source for the newly developed agricultural crops. However, agricultural development was unsuccessful during these years and the acreage was subsequently abandoned and left without irrigation for an extended period of time. Because of the previous agricultural efforts of the 1970s, 1,319 acres (approximately) of land proposed for the solar facility has been previously irrigated. It is estimated, though, that much of the fertile topsoil has likely eroded away since that time. As a result, the future agricultural suitability of this area has been reduced (Burton 2012).

PVID reports that there were 3,911 acre-feet (AF) of groundwater provided to irrigate 768 acres on the Palo Verde Mesa in 2010; however, this groundwater did not support agricultural operations on the Project area. Instead, based on the 2010 PVID report, the agricultural operations on Project area utilized approximately 12,000 AF of water from the PVID surface delivery system to irrigate crops on approximately 1,592 acres. This surface delivery system would also be available to the proposed solar facility. Please refer to Section 3.2.9, *Hydrology and Water Quality*, for a detailed discussion regarding groundwater and water supply.

Regulatory Framework

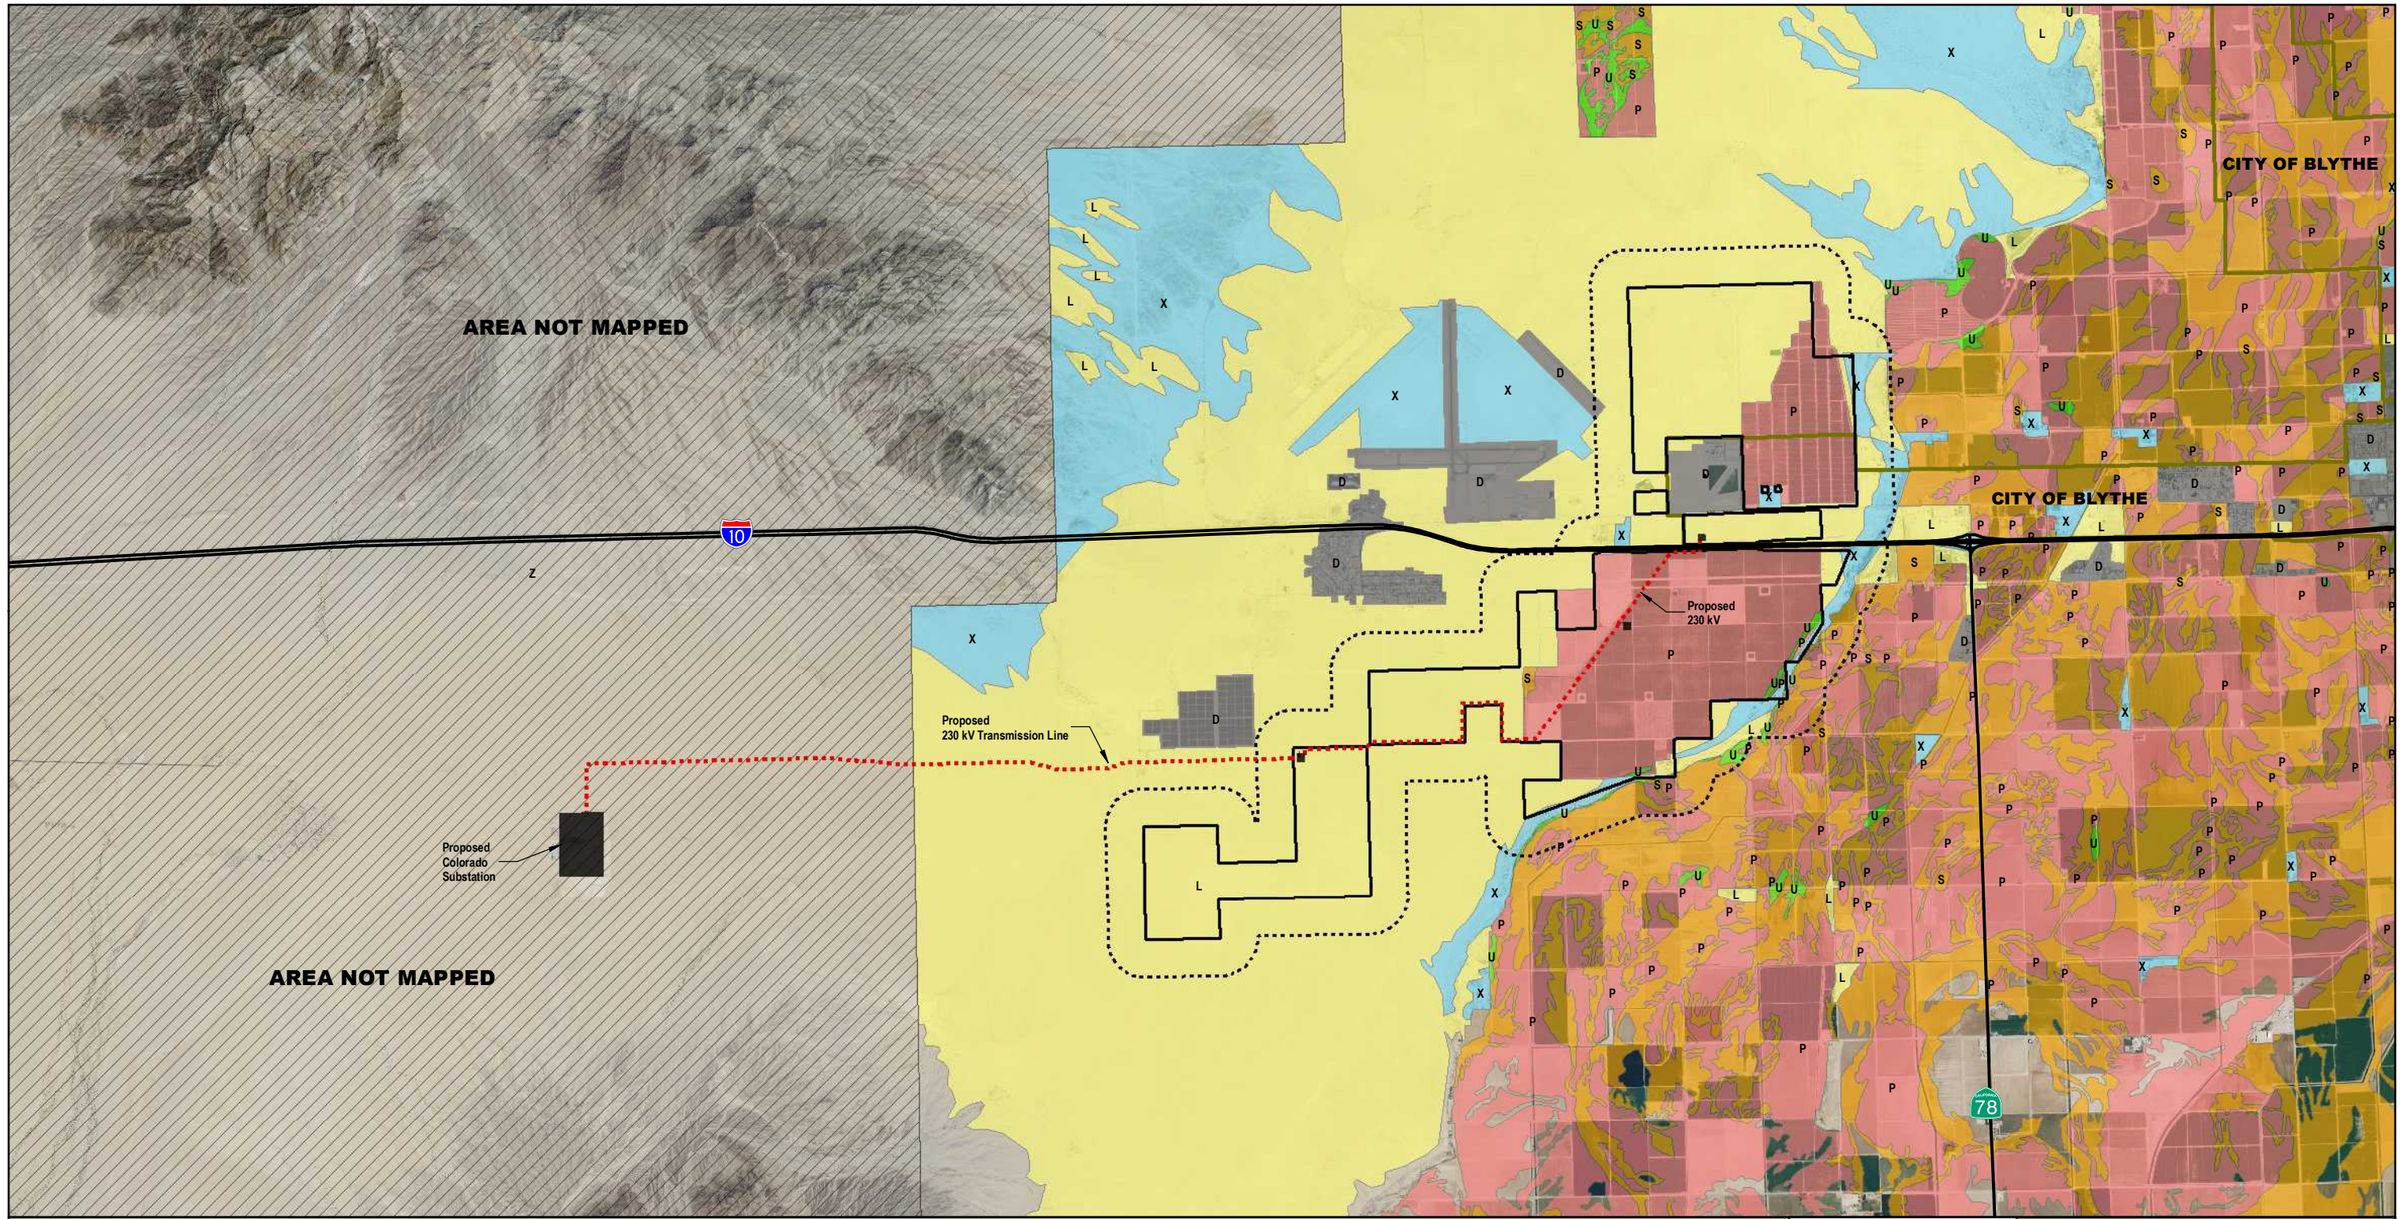
Federal

Farmland Protection Policy Act (7 U.S.C. § 4201)

The purpose of the Farmland Protection Policy Act (FPPA) is to minimize the extent to which federal programs contribute to the unnecessary and irreversible conversion of farmland to non-agricultural uses.

It additionally directs federal programs to be compatible with state and local policies for the protection of farmlands. Congress passed the Agriculture and Food Act of 1981 (Public Law 97-98) containing the FPPA—Subtitle I of Title XV, Section 1539-1549. The final rules and regulations were published in the Federal Register on June 17, 1994.

The FPPA was implemented to minimize the extent to which federal programs contribute to the unnecessary and irreversible conversion of farmland to non-agricultural uses, and to ensure that federal programs are administered in a manner compatible with state and local programs and policies to protect farmland. To fulfill these objectives, the USDA has promulgated criteria and guidelines to assess the effects of the conversion of farmland. The FPPA ensures that, to the extent possible, federal programs are administered to be compatible with state, local units of government, and private programs and policies to protect farmland. Federal agencies are required to develop and review their policies and procedures to implement the FPPA every two years. Projects are subject to FPPA requirements if they may irreversibly convert farmland (directly or indirectly) to non-agricultural use and are completed by a federal agency or with assistance from a federal agency. The FPPA does not authorize the federal government to regulate the use of private or nonfederal land or, in any way, affect the property rights of owners.



For the purpose of FPPA, farmland includes prime farmland, unique farmland, and farmland of statewide or local importance. The USDA has developed definitions for Prime Farmland and Unique Farmland that are used for purposes of the FPPA. The federal definitions are similar to the California definitions, which are set forth below. The primary distinction between the State and federal definitions is that Prime Farmland must be irrigated to satisfy the State definitions, while irrigation is not required under the federal regulations. Under the federal regulations, Prime Farmland could be cropland, pastureland, rangeland, forest land, or other land (but not urban built-up land or water), so long as the land meets required physical and chemical criteria. In its FPPA regulations, the USDA recommends that federal agencies use a Land Evaluation and Site Assessment (LESA) system to evaluate prospective farmland conversion for projects in states that have approved LESA models.

State

California Department of Conservation, Division of Land Resource Protection

The California DOC applies the NRCS soil classifications to identify agricultural lands, and these agricultural designations are used in planning for the present and future of California's agricultural land resources. Pursuant to the California DOC's FMMP, these designated agricultural lands are included in the Important Farmland Maps used in planning for the present and future of California's agricultural land resources. The FMMP was established in 1982 to assess the location, quality, and quantity of agricultural lands and the conversion of these lands. The FMMP provides analysis of agricultural land use and land use changes throughout California. The California DOC has a minimum mapping unit of 10 acres, with parcels that are smaller than 10 acres being absorbed into the surrounding classifications.

The California DOC FMMP produces Important Farmland Maps that document resource quality and land use information. The USDA soil survey information and the corresponding Important Farmland candidacy recommendations are used for assessing local land. The FMMP is intended to assist decision-makers in assessing present status, reviewing trends, and planning for the future of California's agricultural land resources. The FMMP uses eight land classifications: (1) Prime Farmland, (2) Farmland of Statewide

Public Resources Code

PRC Section 21060.1 defines agricultural land for the purposes of assessing environmental impacts using the FMMP. Sections 21061.2 and 21095; and California Environmental Quality Act (CEQA) Guidelines Appendix G, identify the California LESA Model as an optional methodology to access impacts on agriculture and farmland.

The LESA model allows for rating the quality of land for agricultural uses by rating soil resources, project size, water availability, surrounding agricultural lands, and surrounding protected resource lands. The factors are weighted relative to one another, resulting in a numeric score that is measured against thresholds established by the California DOC. Both Riverside County and the BLM have used the LESA model for assessing impacts. The LESA model allows a more precise characterization of the specific attributes of the Project area than an application of the more generalized farmland categories used in the FMMP.

California Land Conservation Act (Williamson Act)

The California Land Conservation Act of 1965, commonly referred to as the Williamson Act, is promulgated in California Government Code Section 51200-51297.4, and therefore is applicable only to specific land parcels within the state of California. The Williamson Act enables local governments to enter into contracts with private landowners for the purpose of restricting specific parcels of land to agricultural or related open space uses in return for reduced property tax assessments. Private land within locally designated agricultural preserve areas is eligible for enrollment under Williamson Act contracts. However, an agricultural preserve must consist of no less than 100 acres; in order to meet this requirement, two or more parcels may be combined if they are contiguous, or if they are in common ownership.

The Williamson Act program is administered by the California DOC in conjunction with local governments, which administer the individual contract arrangements with landowners. The landowner commits the parcel to a 10-year period wherein no conversion out of agricultural use is permitted. Each year the contract automatically renews unless a notice of non-renewal or cancellation is filed. In return, the land is taxed at a rate based on the actual use of the land for agricultural purposes, as opposed to its unrestricted market value. An application for immediate cancellation can also be requested by the landowner, provided that the proposed immediate cancellation application is consistent with the cancellation criteria stated in the California Land Conservation Act and those adopted by the affected county or city. Non-renewal or immediate cancellation does not change the zoning of the property. Participation in the Williamson Act program is dependent on county adoption and implementation of the program and is voluntary for landowners. Riverside County implements the Williamson Act and has adopted Rules and Regulations Governing Agricultural Preserves.

As defined by the Williamson Act, prime agricultural land includes: (1) Class I and II soils as classified by the NRCS; (2) land that qualifies for rating 80 through 100 in the Storie Index Rating by the University of California, Division of Agricultural Sciences; (3) land that supports livestock used for the production of food and fiber and with a carrying capacity of at least one animal unit per acre; (4) land planted with fruit or nut-bearing crops that have a nonbearing period of less than five years and that will normally yield not less than $200 per acre annually during commercial bearing periods; or (5) land that has returned from the production of unprocessed agricultural plant products an annual gross value of not less than $200 per acre for three of the previous five years (Government Code, Section 51201(c)(1)-(5)). The Williamson Act states that a board or council by resolution shall adopt rules governing the administration of agricultural preserves. The rules of each agricultural preserve specify the uses allowed in the preserve. Owners of land within a preserve may then opt to enter into Williamson Act contracts, which restrict the valuation of the property used for property tax purposes in exchange for a long-term commitment to agricultural and compatible uses. Generally, any commercial agricultural use will be permitted within any agricultural preserve and on contracted lands. In addition, local governments may identify compatible uses permitted with a use permit.

California Government Code Section 51238 states that, unless otherwise decided by a local board or council, the erection, construction, alteration, or maintenance of electric and communication facilities, as well as other facilities, are determined to be compatible uses within any agricultural preserve. Section 51238 also states that boards of supervisors may impose conditions on lands or land uses to be placed within preserves to permit and encourage compatible uses in conformity with Section 51238.1.

Further, California Government Code Section 51238.1 allows a board or council to allow as compatible any use that without conditions or mitigations would otherwise be considered incompatible. However, this may occur only if that use meets the following conditions:

- The use will not significantly compromise the long-term productive agricultural capability of the subject contracted parcel or parcels on other contracted lands in agricultural preserves.
- The use will not significantly displace or impair current or reasonably foreseeable agricultural operations on the subject contracted parcel or parcels or on other contracted lands in agricultural preserves. Uses that significantly displace agricultural operations on the subject contracted parcel or parcels may be deemed compatible if they relate directly to the production of commercial agricultural products on the subject contracted parcel or parcels or neighboring lands, including activities such as harvesting, processing, or shipping.
- The use will not result in the significant removal of adjacent contracted land from agricultural or open-space use.

Farmland Security Zone Act

The Farmland Security Zone Act is similar to the Williamson Act and was passed by the California State Legislature in 1999 to ensure that long-term farmland preservation is part of public policy. Farmland Security Zone Act contracts are sometimes referred to as “Super Williamson Act Contracts.” Under the provisions of this act, a landowner already under a Williamson Act contract can apply for Farmland Security Zone status by entering into a contract with the county. Farmland Security Zone classification automatically renews each year for an additional 20 years. In return for a further 35 percent reduction in the taxable value of land and growing improvements (in addition to Williamson Act tax benefits), the owner of the property promises not to develop the property into non-agricultural uses.

Project lands are not under a Farmland Security Act Contract.

Local

Riverside County General Plan

The Riverside County General Plan Land Use Element includes the Agricultural Foundation Component, which contains the agriculture area plan. The Agriculture land use designation has been established to help conserve productive agricultural lands within the county. The intent of the Agriculture Foundation Component and its associated policies is to identify and preserve areas where agricultural uses are the long-term desirable use, as stated in the general plan principles: “Provide for the continued and even expanded production of agricultural products by conserving areas appropriate for agriculture and related infrastructure and supporting services.” In addition, the intent of these policies is to minimize the conflicts between agricultural and urban or suburban uses.

Land Use Element (LU)

Policy LU 6.4. *Retain and enhance the integrity of existing residential, employment, agricultural and open space areas by protecting them from encroachment of land uses that would result in impacts from noise, noxious fumes, glare, shadowing and traffic*.

Policy LU 16.1. *Encourage retaining agriculturally designated lands where agricultural activity can be sustained at an operational scale, where it accommodates lifestyle choice, and in locations where impacts to and from potentially incompatible uses, such as residential uses, are minimized, through incentives such as tax credits*.

Policy LU 16.2. *Protect agricultural uses, including those with industrial characteristics (dairies, poultry, hog farms, etc.) by discouraging inappropriate land division in the immediate proximity and allowing only uses and intensities that are compatible with agricultural uses*.

Policy LU 16.4. *Encourage conservation of productive agricultural lands. Preserve prime agricultural lands for high-value crop production*.

Multipurpose Open Space Element

The Riverside County General Plan Multipurpose Open Space Element (OS) includes the following policies with respect to agricultural land and describes Farmland of Local Importance as follows:

- These farmlands are not covered by the above categories but are of locally significant economic importance. They include the following:
- Lands with soils that would be classified as Prime or Statewide Important Farmlands but lack available irrigation water.
- Lands planted in 1980 or 1981 in dry land grain crops such as barley, oats, and wheat.
- Lands producing major crops for Riverside County but that are not listed as Unique Farmland crops. Such crops are permanent pasture (irrigated), summer squash, okra, eggplant, radishes, and watermelon.
- Dairylands including corrals, pasture, milking facilities, hay and manure storage areas if accompanied with permanent pasture or hayland of 10 acres or more.
- Lands identified by the County with Agriculture land use designations or contracts.
- Lands planted with jojoba that are under cultivation and are of producing age.

Policy OS 7.3. *Encourage conservation of productive agricultural lands and preservation of prime agricultural lands*.

Riverside County General Plan – Palo Verde Valley Area Plan

The majority of the planning area within the Palo Verde Valley is devoted to agriculture and is regulated through the Palo Verde Valley Area Plan (PVVAP). The PVVAP provides for agricultural land use designations along with residential densities and uses. The applicable policy related to agricultural lands included with the PVVAP is provided below.

PVVAP 4.1. *Protect farmland and agricultural resources in Palo Verde Valley through adherence to the Agriculture sections of the General Plan Multipurpose Open Space and Land Use Elements*.

Riverside County Agricultural Preserve Ordinance – Ordinance 509

The Riverside County Agricultural Preserve Ordinance provides for the administration of lands placed in agricultural preserves, including procedures for initiating, filing, and processing requests to establish, enlarge, disestablish, or diminish agricultural preserves, pursuant to the California Land Conservation Act. In establishing the rules under this ordinance, the County found that:

- the preservation of the maximum amount of the limited supply of agricultural land is necessary to the conservation of the County's economic resources, and is necessary not only for the maintenance of agricultural economy of the County, but also for the assurance of adequate, healthful and nutritious food for future residents of the County;
- the discouragement of premature and unnecessary conversion of agricultural land to urban uses is a matter of public interest and will be of benefit to urban dwellers

themselves in that it will discourage discontinuous urban development patterns which unnecessarily increase costs of community services to community residents; and

- in a rapidly urbanizing society agricultural lands have a definite public value as open space, and the preservation in agricultural production of such lands, constitutes an important physical, social, aesthetic and economic asset to existing and pending urban or metropolitan development.

There are no locally designated agricultural preserves affected by the Project.

Riverside County Ordinance 348.4705

Zoning ordinance 348.4705 permits a solar power plant in several districts, including agricultural districts, with a use permit. Ordinance 348.4705 was enacted at the same time as and implements General Plan Policy LU-15.15, which states: "Permit and encourage, in an environmentally and fiscally responsible manner, the development of renewable energy resources and related infrastructure, including but not limited to, the development of solar power plants in the County of Riverside."

Riverside County Ordinance 625, the "Right to Farm" Ordinance

Ordinance 625 factors into Riverside County's standard significance thresholds. It was enacted to conserve, protect, and encourage the development, improvement, and continued viability of agricultural land. The intent of the ordinance is to reduce the loss to the County of its agricultural resources by limiting the circumstances under which agricultural operations may be deemed to constitute a nuisance. Nothing in the ordinance is to be construed to limit the right of any owner of real property to request that the county consider a change in the zoning classification.

City of Blythe General Plan 2025

Policies related to agricultural lands included with the City of Blythe General Plan 2025 are provided below.

Open Space and Conservation Elements

Open Space

Policy 1: *Maintain hillsides and viable agricultural lands as open space for resource conservation and preservation of views*.

Policy 2: *Minimize conflicts between urban and agricultural uses by requiring buffers and greenbelts.*

Agriculture

Policy 9: *Promote continued agricultural use of important farmland outside the urban area*.

Policy 10: *Minimize conflicts between agricultural and urban uses by requiring buffers or use restrictions or using roads or canals to separate these uses*.

City of Blythe Zoning

The City of Blythe Zoning Code lists utility operations facilities among the uses permitted through obtaining a conditional use permit in the Agricultural zoning district. Utility operations facilities are permitted uses in the Service Industrial zoning district.

3.2.3 Air Quality

This section provides an overview of the technical methodology used in collecting baseline conditions, examines the affected environment, and presents the regulatory framework with respect to air quality. Recent regulatory actions on both the federal and State levels address emissions of greenhouse gases and potential global climate change impacts. Under CEQA guidelines, global climate change is addressed as a cumulative impact. Greenhouse gas emissions are discussed in Section 3.2.7. Recent regulatory action on both the federal and State level addresses emissions of greenhouse gases and potential global climate change impacts.

The information in this section is based on the *Air Quality and Global Climate Change Technical Report*, prepared by Scientific Resources Associated (SRA 2013) (provided in Appendix B of this Draft EIR/EA). While this section presents a summary of the findings of the Air Quality and Global Climate Change Technical Report, please refer to that report for more detailed information on the proposed Project and Alternatives' effects on air quality and climate change.

Environmental Setting

Regional Climate

The Project would be located in eastern California in the Colorado Desert. The climate in the Blythe area is categorized as a high desert climate, with dry, hot summers and cool winters. The region is characterized by extreme fluctuations of daily temperatures, strong seasonal winds, and clear skies. January is the coldest month, with a mean low temperature of 37.4 degrees Fahrenheit (°F). July is the hottest month, with a mean high temperature of 108.4°F.

In late winter and early spring, the wind is a prominent feature, with dry winds blowing in the afternoon and evening. Winds in excess of 25 miles per hour (mph), with gusts of 75 mph or more, are not uncommon. Although it is windy during all months, November, December, and January are the calmest. During 2010, the predominant wind direction was from the south approximately 21 percent of the time, with overall average speed of 7.2 mph (SRA 2013). The humidity is below 40 percent most of the year. During most winter nights, and during and after summer rains, the humidity can rise above 50 percent.

Data from the Western Regional Climate Center (WRCC 2010) indicate that temperature and precipitation data have been measured at Blythe from January 1913 through the present. The mean temperature for the Blythe station is 71.6°F, and the mean annual precipitation is 3.8 inches. More than half of the precipitation occurs between November and March. Although rainfall occurs primarily in the winter months, the region is periodically influenced by tropical weather conditions including sudden monsoonal late summer storms. Monthly average temperatures and precipitation for the area are summarized in Table 3.2.3-1.

TABLE 3.2.3-1 MONTHLY AVERAGE TEMPERATURES AND PRECIPITATION, BLYTHE METEOROLOGICAL STATION

MONTH	MONTHLY AVERAGE TEMPERATURES, °F			PRECIPITATION, INCHES
	Maximum	Minimum	Mean	Mean
January	67.6	37.4	52.5	0.51
February	73.0	41.8	57.4	0.46
March	79.4	46.5	57.4	0.34
April	87.4	52.7	70.0	0.12
May	95.5	59.9	77.7	0.03
June	104.2	67.4	85.8	0.05
July	108.4	76.1	92.3	0.19

MONTH	MONTHLY AVERAGE TEMPERATURES, °F			PRECIPITATION, INCHES
	Maximum	Minimum	Mean	Mean
August	106.8	75.4	91.1	0.61
September	101.8	67.3	84.6	0.39
October	90.5	54.8	72.6	0.27
November	76.7	43.4	60.0	0.27
December	67.7	37.6	52.7	0.57
Annual	75.8	49.9	62.9	3.80

Overview of Air Quality Parameters

Air quality is defined by ambient air concentrations of specific pollutants determined by the U.S. Environmental Protection Agency (EPA) to be of concern with respect to the health and welfare of the general public. Seven major pollutants of concern, called "criteria pollutants," are carbon monoxide (CO), sulfur dioxide (SO_2), nitrogen dioxide (NO_2), ozone (O_3), suspended particulate matter less than or equal to 10 microns in diameter (PM_{10}), fine particulate matter less than or equal to 2.5 microns in diameter ($PM_{2.5}$), and lead (Pb) (see Table 3.2.3-2). The EPA has established National Ambient Air Quality Standards (NAAQS) for these pollutants. Areas that violate a federal air quality standard are designated as non-attainment areas.

Ambient air quality refers to the atmospheric concentration of a specific compound (amount of pollutants in a specified volume of air) that occurs at a particular geographic location. The ambient air quality levels measured at a particular location are determined by the interactions of emissions, meteorology, and chemistry. Emission considerations include the types, amounts, and locations of pollutants emitted into the atmosphere. Meteorological considerations include wind and precipitation patterns affecting the distribution, dilution, and removal of pollutant emissions. Chemical reactions can transform pollutant emissions into other chemical substances. Ambient air quality data are generally reported as a mass per unit volume (e.g., micrograms per cubic meter [$\mu g/m^3$] of air) or as a volume fraction (e.g., parts per million [ppm] by volume).

Pollutant emissions typically refer to the amount of pollutants or pollutant precursors introduced into the atmosphere by a source or group of sources. Pollutant emissions contribute to the ambient air concentrations of criteria pollutants, either by directly affecting the pollutant concentrations measured in the ambient air or by interacting in the atmosphere to form criteria pollutants. Primary pollutants, such as CO, SO_2, Pb, and some particulates, are emitted directly into the atmosphere from emission sources.

Secondary pollutants, such as O_3, NO_2, and some particulates, are formed through atmospheric chemical reactions that are influenced by meteorology, ultraviolet light, and other atmospheric processes. PM_{10} and $PM_{2.5}$ are generated as primary pollutants by various mechanical processes (for example, abrasion, erosion, mixing, or atomization) or combustion processes. However, PM_{10} and $PM_{2.5}$ can also be formed as secondary pollutants through chemical reactions or by gaseous pollutants condensing into fine aerosols. In general, emissions that are considered "precursors" to secondary pollutants in the atmosphere (such as reactive organic gases [ROG] and oxides of nitrogen [NO_x], which are considered precursors for O_3) are the pollutants for which emissions are evaluated to control the level of O_3 in the ambient air.

Toxic air contaminants (TACs) are substances that have the potential to be emitted into the ambient air that have been determined to present some level of acute or chronic health risk (cancer or non-cancer) to the general public. These pollutants may be emitted in trace amounts from various types of sources, including combustion sources. TACs that may be produced by construction and operation of the proposed Project are listed in Table 3.2.3-3, including the most relevant health effects.

Existing Air Quality

The proposed Project and Alternatives are located within the Mojave Desert Air Quality Management District (MDAQMD), which collects ambient air quality data from several air quality monitoring stations within its jurisdiction. The closest monitoring site to the Project is located at 445 West Murphy Street in Blythe and measures O_3. The nearest monitoring station that measures $PM_{2.5}$ is located in Victorville; measurements in Victorville are not likely to be representative of conditions in the Project area (solar facility site and gen-tie line). The nearest monitoring station that measures CO, NO_2, and PM_{10} is located in Barstow, which may also be substantially different from conditions in Blythe. According to the Northern and Eastern Colorado Desert Coordinated Management (NECO) Plan, the ozone standard is exceeded due to long-distance transport of pollutants from the Los Angeles Basin, while the PM_{10} exceedance is due to natural sources found in a desert environment and various land uses. These uses include OHV use, mining, agricultural use, and livestock grazing. The PM_{10} concentrations are from fugitive dust emission sources, rather than from combustion particulate or secondary particulate emission sources. Table 3.2.3-4 provides a summary of available ambient air quality data for the Project region.

Areas that do not meet the NAAQS or California Ambient Air Quality Standards (CAAQS) for a given criteria pollutant are designated as “non-attainment areas” by the EPA and/or the California Air Resources Board (CARB). Further classifications are given to non-attainment areas to identify the severity and number of violations experienced, and the year in which attainment is anticipated based on implementation of attainment plans. In circumstances where there is not enough ambient data available to support designation as either attainment or non-attainment, the area can be designated as unclassified. An unclassified area is normally treated by the EPA the same as an attainment area for regulatory purposes. The air basin for the Project area is considered an unclassified/attainment area for all of the NAAQS. The air basin is considered a moderate non-attainment area for the CAAQS for O_3 and a non-attainment area for the CAAQS for PM_{10}. The air basin is considered unclassified/attainment for all other CAAQS (refer to Table 3.2.3-3 for air quality in relation to standards).

TABLE 3.2.3-2 AMBIENT AIR QUALITY STANDARDS AND HEALTH EFFECTS

POLLUTANT	CALIFORNIA STANDARDS	NATIONAL STANDARDS [A]		MOST RELEVANT HEALTH EFFECTS
		Primary [b,c]	Secondary [b,d]	
Ozone (O_3)	0.070 ppm, 8-hour average; (137 µg/m^3)	0.075 ppm, 8-hour average; (147 µg/m^3)	Same as primary	O_3 is considered a respiratory irritant and prolonged exposure can reduce lung function, aggravate asthma and increase susceptibility to respiratory infections. Exposure to levels of ozone above the current ambient air quality standard can lead to human health effects such as lung inflammation, tissue damage, impaired lung function, coughing, chest tightness, shortness of breath, and the worsening of asthma symptoms. Harmful health effects are associated with outdoor workers, athletes, children and others who spend greater amounts of time outdoors during smoggy periods.
	0.09 ppm, 1-hour average; (180 µg/m^3)	—	—	
Carbon monoxide (CO)	9.0 ppm, 8-hour average; (10 mg/m^3)	9 ppm, 8-hour average; (10 mg/m^3)	—	Exposure to CO near the levels of the ambient air quality standards can lead to fatigue, headaches, confusion, and dizziness. CO interferes with the blood's ability to carry oxygen. Exposure to CO is especially harmful to those with heart disease and has been associated with aggravation of angina pectoris and other aspects of coronary heart disease, decreased exercise tolerance in people with peripheral vascular disease and lung disease, impairment of central nervous system functions, and possible increased risk to fetuses.
	20 ppm, 1-hour average; (23 mg/m^3)	35 ppm (40 mg/m^3)	—	
Nitrogen dioxide (NO_2)	0.030 ppm, Annual Arithmetic Mean; (56 µg/m^3)	0.053 ppm (100 µg/m^3)	Same as primary	NO_2 is a respiratory irritant and may affect those with existing respiratory illness, including asthma. Exposure to NO_2 along with other traffic-related pollutants, is associated with respiratory symptoms, episodes of respiratory illness and impaired lung functioning.
	0.18 ppm, 1-hour average, 1-hour average; (338 µg/m^3)	0.100 ppm (188 µg/m^3)	—	
Sulfur dioxide (SO_2)	0.04 ppm, 24-hour average (105 µg/m^3)	—	—	Effects from SO_2 exposures at levels near the one-hour standard include bronchoconstriction accompanied by symptoms, which may include wheezing, shortness of breath and chest tightness, especially during exercise or physical activity. Children, the elderly, and people with asthma, cardiovascular disease or chronic lung disease (such as bronchitis or emphysema) are most susceptible to these symptoms. SO_2 is a respiratory irritant that can cause narrowing of the airways leading to wheezing and shortness of breath. Long-term exposure to SO_2 can cause respiratory illness and aggravate existing cardiovascular disease.
	----	—	0.5 ppm, 3-hour average (1,300 µg/m^3)	
	0.25 ppm, 1-hour average; (655 µg/m^3)	0.075 ppm (196 µg/m^3)	—	

POLLUTANT	CALIFORNIA STANDARDS	NATIONAL STANDARDS [A]		MOST RELEVANT HEALTH EFFECTS
		Primary [b,c]	Secondary [b,d]	
PM_{10}	Annual Arithmetic Mean; 20 µg/m^3,	—	—	(a) Excess deaths from short-term exposures and exacerbation of symptoms in sensitive patients with respiratory disease; (b) Excess seasonal declines in pulmonary function, especially in children.
	24-hour average, 50 µg/m^3	150 µg/m^3	Same as primary	
$PM_{2.5}$ [(e)]	Annual Arithmetic Mean; 12 µg/m^3	12.0 µg/m^3	Same as primary	(a) Excess deaths from short-term exposures and exacerbation of symptoms in sensitive patients with respiratory disease; (b) Excess seasonal declines in pulmonary function, especially in children
	—	35 µg/m^3, 24-hour average	Same as primary	
Lead	—	0.15 µg/m^3, rolling 3-month average	Same as primary	Because lead is only slowly excreted, exposures to small amounts of lead from a variety of sources can accumulate to harmful levels. Effects from inhalation of lead near the level of the ambient air quality standard include impaired blood formation and nerve conduction. Lead can adversely affect the nervous, reproductive, digestive, immune, and blood-forming systems. Symptoms can include fatigue, anxiety, short-term memory loss, depression, weakness in the extremities, and learning disabilities in children. Lead is also classified as a probable human carcinogen.
	—	1.5 µg/m^3, calendar quarter	Same as primary	
	30-day average; 1.5 µg/m^3	—	—	
Hydrogen Sulfide (H_2S)	0.03 ppm, 1-hour average; (42 µg/m^3)	—	—	Breathing H_2S at levels above the standard would result in exposure to a very disagreeable odor. The California Air Resources Board (CARB) has concluded that the ambient standard for H_2S is adequate to protect public health.

Source: SRA 2013

Notes: µg/m3 = micrograms per cubic meter; ppm = parts per million

(a) Standards other than the 1-hour ozone, 24-hour PM_{10}, 24-hour $PM_{2.5}$, and those based on annual averages are not to be exceeded more than once a year. The 8-hour ozone national standard has replaced the 1-hour ozone national standard.

(b) Concentrations are expressed first in units in which they were promulgated. Equivalent units given in parenthesis.

(c) Primary Standards: The levels of air quality necessary, with an adequate margin of safety to protect the public health. Each state must attain the primary standards no later than three years after that state's implementation plan is approved by the EPA.

(d) Secondary Standards: The levels of air quality necessary to protect the public welfare from any known or anticipated adverse effects of a pollutant.

(e) The NAAQS for $PM_{2.5}$ was lowered to 12 µg/m^3 in December, 2012.

TABLE 3.2.3-3 TOXIC AIR CONTAMINANTS AND HEALTH EFFECTS

CONTAMINANT	CHARACTERISTICS	MOST RELEVANT HEALTH EFFECTS
Sulfates	A fully oxidized ionic form of sulfur primarily derived from combustion of petroleum based fuels.	Effects of sulfate exposure at levels above the standard include a decrease in ventilatory function, aggravation of asthmatic symptoms and an increased risk of cardio-pulmonary disease.
Vinyl Chloride	A chlorinated hydrocarbon that is a colorless gas with a mild, sweet odor.	Short-term exposure to high levels of vinyl chloride in air causes central nervous system effects, such as dizziness, drowsiness and headaches. Long-term exposure through inhalation and oral exposure causes liver damage. Cancer is a major concern from exposure via inhalation.
Visibility Reducing Particles	Suspended particulate matter, which is a complex mixture of tiny particles that consists of dry solid fragments, solid cores with liquid coatings, and small droplets of liquid.	No specific health effects noted.
Benzene	Benzene is found in the air from emissions from burning coal and oil, gasoline service stations, and motor vehicle exhaust.	Short-term inhalation exposure of humans to benzene may cause drowsiness, dizziness, headaches, as well as eye, skin, and respiratory tract irritation, and, at high levels, unconsciousness. Long-term inhalation exposure has caused various disorders in the blood, including reduced numbers of red blood cells and aplastic anemia, in occupational settings. Reproductive effects and increased incidences of leukemia have been observed in humans occupationally exposed to benzene. A Group A human carcinogen.
Formaldehyde	Formaldehyde exposure may occur by breathing contaminated indoor air, tobacco smoke, or ambient urban air.	Short-term and long-term inhalation exposure to formaldehyde in humans can result in respiratory symptoms, and eye, nose, and throat irritation. Short-term high exposure may lead to eye, nose and throat irritation, and in the respiratory tract, nasal obstruction, pulmonary edema and dyspnea. Prolonged or repeated exposures have been associated with allergic sensitization, respiratory symptoms, and decrements in lung function. A Group B1 probable human carcinogen.
Diesel Particulate Matter	Diesel particulate matter is emitted from both mobile and stationary sources of diesel powered on-road and off-road equipment.	Occupational exposures to diesel exhaust particles have been associated with significant cross-shift decreases in lung function. Increased cough, labored breathing, chest tightness, and wheezing have been associated with exposure to diesel exhaust in bus garage workers. A number of adverse long-term non-cancer effects have been associated with exposure to diesel exhaust. Occupational studies have shown that there may be a greater incidence of cough, phlegm and chronic bronchitis among those exposed to diesel exhaust than among those not exposed. Reductions in pulmonary function have also been reported following occupational exposures in chronic studies. Exposure to diesel exhaust has also shown cellular changes in laboratory animals.
Acrolein	Acrolein is a powerful irritant.	Short-term exposures to levels above 1.0 ppm result in mucous hypersecretion and exacerbation of allergic airway response in animal models. Moderately higher exposures may result in severe lacrimation, and irritation of the mucous membranes of the respiratory tract. Death due to respiratory failure has been associated with high level exposures. Long term exposure to acrolein may result in structural and functional changes in the respiratory tract, including lesions in the nasal mucosa, and pulmonary inflammation.

CONTAMINANT	CHARACTERISTICS	MOST RELEVANT HEALTH EFFECTS
1,3–Butadiene	Motor vehicle exhaust is a constant source of 1,3-butadiene. Although 1,3-butadiene breaks down quickly in the atmosphere, it is usually found in ambient air at low levels in urban and suburban areas.	Short-term exposure to 1,3-butadiene by inhalation in humans results in irritation of the eyes, nasal passages, throat, and lungs. The EPA has classified 1,3-butadiene as carcinogenic to humans by inhalation.
Naphthalene	Naphthalene is used in the production of phthalic anhydride; it is also used in mothballs.	Short-term exposure of humans to naphthalene by inhalation, ingestion, and dermal contact is associated with hemolytic anemia, damage to the liver, and neurological damage. Cataracts have also been reported in workers acutely exposed to naphthalene by inhalation and ingestion. Long-term exposure of workers and rodents to naphthalene has been reported to cause cataracts and damage to the retina. Hemolytic anemia has been reported in infants born to mothers who "sniffed" and ingested naphthalene (as mothballs) during pregnancy. A Group C, possible human carcinogen.
Polycyclic Organic Matter (POM)	The term polycyclic organic matter (POM) defines a broad class of compounds that includes the polycyclic aromatic hydrocarbon compounds (PAHs), of which benzo[a]pyrene is a member. POM compounds are formed primarily from combustion and are present in the atmosphere in particulate form. Sources of air emissions are diverse and include cigarette smoke, vehicle exhaust, home heating, laying tar, and grilling meat.	Cancer is the major concern from exposure to POM. Epidemiologic studies have reported an increase in lung cancer in humans exposed to coke oven emissions, roofing tar emissions, and cigarette smoke; all of these mixtures contain POM compounds. Animal studies have reported respiratory tract tumors from inhalation exposure to benzo[a]pyrene and forestomach tumors, leukemia, and lung tumors from oral exposure to benzo[a]pyrene. The EPA has classified seven PAHs (benzo[a]pyrene, benz[a]anthracene, chrysene, benzo[b]fluoranthene, benzo[k]fluoranthene, dibenz[a,h]anthracene, and indeno[1,2,3-cd]pyrene) as Group B2, probable human carcinogens.

TABLE 3.2.3-4 SUMMARY OF AVAILABLE AIR QUALITY DATA FOR THE PROJECT AREA (2006-2011)

AIR QUALITY INDICATOR	2006	2007	2008	2009	2010	2011
Ozone (O_3)[1,3]						
Peak 1-hour value (ppm)	0.073	0.092	0.074	0.072	0.072	0.066
Days above state standard (0.09 ppm)	0	0	0	0	0	0
Peak 8-hour value (ppm)	0.059	0.075	0.071	0.066	0.067	0.061
Days above state standard (0.070 ppm)	0	1	1	0	0	0
Days above federal standard (0.075 ppm)[1,2]	0	0	0	0	0	0
Particulate matter less than or equal to 10 microns in diameter (PM_{10})[4]						
Peak 24-hour value ($\mu g/m^3$)	80	202	93	76	38	108
Days above state standard (50 $\mu g/m^3$)	2	5	2	2	0	2
Days above federal standard (150 $\mu g/m^3$)	0	1	0	0	0	0
Annual Arithmetic Mean (ppm)	21.9	29.8	26.1	26.8	18.8	21.5
Carbon Monoxide[4]						
Peak 8-hour value ($\mu g/m^3$)	1.19	0.70	1.23	0.89	0.89	1.35
Days above state and federal standard (9 ppm)	0	0	0	0	0	0

AIR QUALITY INDICATOR	2006	2007	2008	2009	2010	2011
Peak 8-hour value (μg/m³)	3.5	1.4	1.4	1.2	1.1	4.3
Days above state standard (20 ppm)	0	0	0	0	0	0
Days above federal standard (35 ppm)	0	0	0	0	0	0
Nitrogen Dioxide (NO_2)[4]						
Peak 1-hour value (ppm)	0.082	0.073	0.081	0.060	0.062	0.072
Days above state standard (0.18 ppm)	0	0	0	0	0	0
Annual Arithmetic Mean (ppm))	0.022	0.020	0.019	0.016	0.017	0.017

Notes: [1] The federal O_3 standard was revised downward in 2008 to 0.075 ppm.
[2] The federal eight-hour ozone standard was previously defined as 0.08 ppm (1 significant digit). Measurements were rounded up or down to determine compliance with the standard; therefore, a measurement of 0.084 ppm is rounded to 0.08 ppm. The 8-hour ozone ambient air quality standards are met at an ambient air quality monitoring site when the average of the annual fourth-highest daily maximum 8-hour average ozone concentration is less than or equal to the standard.
[3] Data from the Blythe monitoring station.
[4] Data from the Barstow monitoring station. Data for 1-hour CO concentrations unavailable.
ppm = parts per million; μg/m³ = micrograms per cubic meter; * = not available

Sensitive Receptors

Sensitive receptors are people who are considered to be more sensitive than others to air pollutants. The reasons for greater than average sensitivity include pre-existing health problems, proximity to emissions sources, or duration of exposure to air pollutants. Schools, hospitals, and convalescent homes are considered to be relatively sensitive to poor air quality because children, elderly people, and the infirm are more susceptible to respiratory distress and other air quality-related health problems than the general public. Residential areas are considered sensitive to poor air quality because people usually stay home for extended periods of time, with associated greater exposure to ambient air quality. Recreational uses are also considered sensitive due to the greater exposure to ambient air quality conditions because vigorous exercise associated with recreation places a high demand on the human respiratory system.

The site is located in proximity to rural agricultural lands, undeveloped lands, uses associated with the Blythe Airport, power generation, local roads, and interstate highway and other non-sensitive uses. However, some sensitive air quality receptors are located within one mile of the site. There are approximately 369 residences within one mile of the proposed solar facility site, nine of which are individual residences located within 1,000 feet of the site (see Figure 3.2.1-1). The closest residence is located approximately 260 feet away. In addition, the Project would be approximately 0.4 mile (2,200 feet) from the Mesa Verde Park and approximately 0.8 mile (4,400 feet) from the Roy Wilson Community and Child Center. No schools, hospitals, or convalescent homes are located within one mile of the proposed Project.

Regulatory Setting

Air quality in the Project area's air basin is regulated by federal, State, and local regulatory agencies with the responsibility for maintaining ambient air quality within federal and State standards. The EPA is the federal agency responsible for establishing air quality regulations on a federal level. The federal Clean Air Act (CAA) and its subsequent amendments establish air quality regulations and the NAAQS and delegate the enforcement of these standards to the states. In California, the CARB is responsible for enforcing air pollution regulations. The CARB has in turn delegated the responsibility of regulating stationary emission sources to regional air agencies. In the Project area's air basin, which is located in eastern Riverside County, the MDAQMD has this responsibility.

The following sections summarize the air quality rules and regulations that apply to the Project.

Federal

The federal CAA applies to all air emission sources and to all areas within the United States. Regulations adopted under the CAA that would apply to the Project would include the NAAQS as well as other requirements that have been adopted as part of the MDAQMD's federally approved plans and programs.

As indicated in Federal Register Volume 75, No. 11, Page 2938, the EPA is considering lowering the 8-hour O_3 standard from 0.075 ppm, which is its current level, to a lower level within the range of 0.060 and 0.070 ppm. The lower level is proposed to provide increased protection for children and other "at risk" populations against O_3 health effects.

Federal Emission Standards. The EPA has also adopted on-road and off-road engine emission reduction requirements, including Federal Exhaust and Evaporative Emission Standards for Light-Duty Vehicles and Light-Duty Trucks, Federal Emission Standards for Heavy-Duty and Non-road Engines, and other emission control programs that affect the Project's potential impacts to air quality through the phase-in of clean fuel and engine requirements.

General Conformity Rule. The General Conformity Rule (40 Code of Federal Regulations [CFR] Part 93) requires that federal agencies demonstrate that federal actions conform with the applicable State Implementation Plan (SIP) in order to ensure that federal activities do not hamper local efforts to control air pollution. The EPA general conformity rule applies to federal actions occurring in nonattainment or maintenance areas when the total direct and indirect emissions of nonattainment pollutants (or their precursors) exceed specified thresholds. The *de minimis* emission thresholds are based on the attainment status of each air basin. Since the Project is located in an air basin that is designated attainment for all federal criteria pollutants, it is not subject to the General Conformity emissions thresholds.

State

The California Clean Air Act (CCAA) was signed into law in 1988 and, for the first time, clearly spelled out in statute California's air quality goals, planning mechanisms, regulatory strategies, and standards of progress. The CCAA provides the State with a comprehensive framework for air quality planning regulation. Prior to passage of the CCAA, federal law contained the only comprehensive planning framework. As part of its authority within the state of California, and as allowed under the federal CAA, CARB has established the CAAQS. The CAAQS are at least as stringent as the NAAQS. Both the NAAQS and CAAQS are shown in Table 3.2.3-4.

The CARB has oversight over air quality in the state of California. The CARB is responsible for the development of the SIP, which provides a framework for attaining and maintaining the NAAQS within the state of California. In turn, development of individual inputs to the SIP is the responsibility of local air pollution control agencies. Regulation of individual stationary sources has been delegated to local air pollution control agencies.

The CARB is responsible for developing programs designed to reduce emissions from non-stationary sources, including motor vehicles and off-road equipment. The CARB and the California Office of Environmental Health Hazard Assessment (OEHHA) are also responsible for developing regulations governing TACs. TACs include air pollutants that can cause serious illnesses or increased mortality, even in low concentrations. The CARB and OEHHA identify specific air pollutants as TACs, develop health thresholds for exposure to TACs, and develop guidelines for conducting health risk assessments for sources of TAC emissions.

Local

As discussed above, the Project would be located in the jurisdiction of the MDAQMD. The MDAQMD is responsible for regulating stationary sources of air emissions in the Project area's air basin. Stationary

sources that have the potential to emit air pollutants into the ambient air are subject to the Rules and Regulations adopted by the MDAQMD. The following MDAQMD rules are applicable to the Project.

Rule 401 – Visible Emissions. Rule 401 states that a person shall not discharge into the atmosphere, from any single source of emissions whatsoever, any air contaminant for a period or periods aggregating more than three minutes in any one hour which is:

As dark or darker in shade as that designated as No. 1 on the Ringelmann Chart, as published by the U.S. Bureau of Mines, or
Of such opacity as to obscure an observer's view to a degree equal to or greater than does smoke described in Subsection A [of the Rules].

Rule 402 - Nuisance. Rule 402 prohibits a person from discharging from any source whatsoever such quantities of air contaminants or other material which cause injury, detriment, nuisance or annoyance to any considerable number of persons or to the public, or which endanger the comfort, repose, health or safety of any such persons or the public, or which cause, or have a natural tendency to cause, injury or damage to business or property.

Rule 403 – Fugitive Dust. Rule 403 requires control of fugitive dust emissions during activities such as construction that have the potential to generate dust. The provisions of Rule 403 include the following:

1) A person shall not cause or allow the emissions of fugitive dust from any transport, handling, construction or storage activity so that the presence of such dust remains visible in the atmosphere beyond the property line of the emission source. (Does not apply to emissions emanating from unpaved roadways open to public travel or farm roads. This exclusion shall not apply to industrial or commercial facilities).
2) A person shall take every reasonable precaution to minimize fugitive dust emissions from wrecking, excavation, grading, clearing of land and solid waste disposal operations.
3) A person shall not cause or allow particulate matter to exceed 100 micrograms per cubic meter when determined as the difference between upwind and downwind samples collected on high volume samplers at the property line for a minimum of five hours.
4) A person shall take every reasonable precaution to prevent visible particulate matter from being deposited upon public roadways as a direct result of their operations. Reasonable precautions shall include, but are not limited to, the removal of particulate matter from equipment prior to movement on paved streets or the prompt removal of any material from paved streets onto which such material has been deposited.
5) Subsections (a) and (c) shall not be applicable when the wind speed instantaneously exceeds 40 kilometers (25 miles) per hour, or when the average wind speed is greater than 24 kilometers (15 miles) per hour. The average wind speed determination shall be on a 15 minute average at the nearest official air-monitoring station or by wind instrument located at the site being checked.
6) The provisions of this rule shall not apply to agricultural operations.

Rule 403.2 – Fugitive Dust. Rule 403.2 applies to construction sites, and requires the owner or operator of any Construction/Demolition source to:

1) Use periodic watering for short-term stabilization of Disturbed Surface Area to minimize visible fugitive dust emissions. For purposes of this Rule, use of a water truck to maintain moist disturbed surfaces and actively spread water during visible dusting episodes shall be considered sufficient to maintain compliance;
2) Take actions sufficient to prevent project-related Trackout onto paved surfaces;
3) Cover loaded haul vehicles while operating on Publicly Maintained paved surfaces;
4) Stabilize graded site surfaces upon completion of grading when subsequent development is delayed or expected to be delayed more than thirty days, except when such a delay is due to precipitation that dampens the disturbed surface sufficiently to eliminate Visible Fugitive Dust emissions;

5) Cleanup project-related Trackout or spills on Publicly Maintained paved surfaces within twenty-four hours; and
6) Reduce non-essential Earth-Moving Activity under High Wind conditions. For purposes of this Rule, a reduction in Earth-Moving Activity when visible dusting occurs from moist and dry surfaces due to wind erosion shall be considered sufficient to maintain compliance.

Rule 403.2 also requires that the owner/operator of a Construction/Demolition source disturbing 100 or more acres shall, in addition to the provisions of subsection (2):

7) Prepare and submit to the MDAQMD, prior to commencing Earth-Moving Activity, a dust control plan that describes all applicable dust control measures that will be implemented at the project;
8) Provide Stabilized access route(s) to the project site as soon as is feasible. For purposes of this Rule, as soon as is feasible shall mean prior to the completion of Construction/Demolition activity;
9) Maintain natural topography to the extent possible;
10) Construct parking lots and paved roads first, where feasible; and
11) Construct upwind portions of project first, where feasible.

Rule 404 – Particulate Matter Concentration. Rule 404 restricts emissions of particulate matter from any source based on the concentrations specified in Table 404(a).

Rule 405 – Solid Particulate Matter Weight. Rule 405 restricts emissions of particulate matter from any source based on the concentrations specified in Table 405(a).

Rule 406 – Specific Contaminants. Rule 406 restricts emissions of sulfur compounds to 500 ppm or less, and restricts emissions of halogens, which are not generally emitted from construction projects.

Rule 407 – Liquid and Gaseous Air Contaminants. Rule 407 restricts emissions of carbon monoxide to 2,000 ppm or less.

Rule 408 – Circumvention. Rule 408 restricts the building, erection, installation or use of any equipment, the use of which, without resulting in a reduction in the total release of air contaminants to the atmosphere, reduces or conceals an emission which would otherwise constitute a violation of Chapter 3 (commencing with Section 41700) of Part 4, of Division 26 of the Health and Safety Code or of the MDAQMD Rules.

Rule 409 – Combustion Contaminants. Rule 409 restricts discharge into the atmosphere from the burning of fuel, combustion contaminants exceeding 0.23 gram per cubic meter (0.1 grain per cubic foot) of gas calculated to 12 percent of carbon dioxide (CO_2) at standard conditions averaged over a minimum of 25 consecutive minutes.

Rule 431 – Sulfur Content of Fuels. Rule 431 restricts the use of any gaseous fuel containing sulfur compounds in excess of 800 ppm calculated as hydrogen sulfide at standard conditions, or any liquid or solid fuel having a sulfur content in excess of 0.5 percent by weight.

Rule 442 – Usage of Solvents. Rule 442 restricts the emission of volatile organic compounds (VOCs) from any solvent material to 1,190 pounds per month, and requires proper storage and handling of VOC-containing solvents.

Riverside County General Plan

The Riverside County General Plan Air Quality Element (AQ) includes policies that limit emissions within the County boundaries. The goal is to support efforts to decrease region-wide pollution emissions, as surrounding jurisdictions significantly impact Riverside County's air quality. Policies were designed to establish a regional basis for improving air quality. The Riverside County General Plan's Air Quality Element (AQ) discusses the following applicable policies regarding air quality within Riverside County:

countywide policies that address air quality within the County boundaries are also located in the Land Use Element (LU) of the County General Plan, and include:

Air Quality Element

Policy AQ 1.1. *Promote and participate with regional and local agencies, both public and private, to protect and improve air quality.*

Policy AQ 1.4. *Coordinate with the South Coast Air Quality Management District (SCAQMD) and MDAQMD to ensure that all elements of air quality plans regarding reduction of air pollution emissions are being enforced.*

Policy AQ 1.5. *Establish and implement air quality, land use and circulation measures that improve not only the County's environment but the entire region.*

Policy AQ 2.1. *The County land use planning efforts shall assure that sensitive receptors are separated and protected from polluting point sources to the greatest extent possible.*

Policy AQ 2.2. *Require site plan designs to protect people and land uses sensitive to air pollution through the use of barriers and/or distance from emissions sources when possible.*

Policy AQ 2.3. *Encourage the use of pollution control measures such as landscaping, vegetation and other materials, which trap particulate matter or control pollution.*

Policy AQ 4.1. *Encourage the use of building materials/methods which reduce emissions.*

Policy AQ 4.5. *Require stationary pollution sources to minimize the release of toxic pollutants through:*

- *Design features;*
- *Operating procedures;*
- *Preventive maintenance;*
- *Operator training; and*
- *Emergency response planning*

Policy AQ 4.6. *Require stationary air pollution sources to comply with applicable air district rules and control measures.*

Policy AQ 4.7. *To the greatest extent possible, require every project to mitigate any of its anticipated emissions which exceed allowable emissions as established by the SCAQMD, MDAQMD, SCAB* [South Coast Air Basin]*, the Environmental Protection Agency and the California Air Resources Board.*

Policy AQ 4.9. *Require compliance with SCAQMD Rules 403 and 403.1, and support appropriate future measures to reduce fugitive dust emanating from construction sites.*

Policy AQ 4.10. *Coordinate with the SCAQMD and MDAQMD to create a communications plan to alert those conducting grading operations in the County of first, second, and third stage smog alerts, and when wind speeds exceed 25 miles per hour. During these instances all grading operations should be suspended.*

Policy AQ 5.1. *Utilize source reduction, recycling and other appropriate measures to reduce the amount of solid waste disposed of in landfills.*

Policy AQ 16.1. *Cooperate with local, regional, state and federal jurisdictions to better control particulate matter.*

Policy AQ 16.2. *Encourage stricter state and federal legislation on bias belted tires, smoking vehicles, and vehicles that spill debris on streets and highways, to better control particulate matter.*

Policy AQ 16.3. *Collaborate with the SCAQMD and MDAQMD to require and/or encourage the adoption of regulations or incentives to limit the amount of time trucks may idle.*

Policy AQ 16.4. *Collaborate with the EPA, SCAQMD, MDAQMD, and warehouse owners and operators to create regulations and programs to reduce the amount of diesel fumes released due to warehousing operations.*

Policy AQ 17.3. *Identify and create a control plan for areas within the County prone to wind erosion of soil.*

Policy AQ 17.4. *Adopt incentives, regulations and/or procedures to manage paved and unpaved roads and parking lots so they produce the minimum practicable level of particulates.*

Policy AQ 17.8. *Adopt regulations and programs necessary to meet state and federal guidelines for diesel emissions.*

Land Use Element

Policy LU 6.2(a). *The facility is compatible in scale and design with surrounding land uses, and does not generate excessive noise, traffic, light, fumes, or odors that might have a negative impact on adjacent neighborhoods.*

Policy LU 6.4. *Retain and enhance the integrity of existing residential, employment, agricultural, and open space areas by protecting them from encroachment of land uses that would result in impacts from noise, noxious fumes, glare, shadowing, and traffic.*

City of Blythe General Plan

City policies in the City of Blythe General Plan 2025 (2007) related to air quality are located in the Open Space Element, Guiding Policies of the City General Plan, and include:

Open Space and Conservation Element

Policy 11: *Strive to meet all regional and federal ambient air quality standards and reduce the generation of air pollutants.*

Policy 14: *Whenever feasible, coordinate air quality, transportation, and land use planning efforts with other jurisdictions and public agencies responsible for air quality management.*

3.2.4 Biological Resources

This section describes the environmental setting and regulatory framework in regards to biological resources for the proposed Project and Alternatives.

The information in this section is based on the *Blythe Mesa Solar Project Biological Resources Technical Report,* prepared by POWER Engineers, Inc. 2013 (Appendix C1 of this Draft EIR/EA), the *Blythe Mesa Solar Project 230 kV Transmission Line Alternative Habitat Assessment Report,* prepared by POWER Engineers, Inc. 2013 (Appendix C2 of this Draft EIR/EA), the *Western Burrowing Owl Survey Report* prepared by POWER Engineers, Inc. 2013 (Appendices C3 of this Draft EIR/EA), the *Bird and Bat Conservation Plan* prepared by POWER Engineers, 2013 (Appendix C4 of this Draft EIR/EA), and the *Review of Federal Waters* prepared by POWER Engineers, Inc. 2013 (Appendices C5 of this Draft EIR/EA).

Environmental Setting

The Project Area is in the Palo Verde Valley, which is along the western edge of the Colorado River. The topography is relatively flat and slopes toward the southeast; elevations range from 260 to 400 feet amsl. The study area is near the Big Maria Mountains on the northwest, the McCoy Mountains on the west, the Mule Mountains on the southwest, and the Colorado River on the east. These mountain ranges, trending northwest to southeast, create a natural barrier between the Colorado River and the greater Colorado Desert.

Approximately 70 percent of the solar array area is actively cultivated agricultural land, 24 percent is previously disturbed by agricultural or military activities, and six percent remains undisturbed. Agricultural land use within the solar array site includes drip-irrigated citrus orchards, flood-irrigated alfalfa, non-irrigated winter wheat, abandoned jojoba orchards, and fallow fields. The gen-tie line corridors would pass through BLM lands and other private lands mainly comprised of desert scrub habitat and disturbed lands associated with existing infrastructure. Several utility lines and maintenance roads run through or parallel the gen-tie line corridors. Additionally, the Project Area has been previously disturbed by off-road vehicle use, trash dumping, and historic use for military training during World War II. The Project area is located in the Colorado Desert in gently rolling open terrain dominated by desert scrub vegetation. The Colorado Desert is a part of the larger Sonoran Desert, which extends across the southwest United States and into Mexico. The climate is very hot and dry in the summer months, and cool in the winter.

Surface water is minimal on Palo Verde Mesa and consists of limited seasonal and perennial sources. Perennial water comes from McCoy Springs in the McCoy Mountains west of the Project Area and the Colorado River, which lies eight miles east of the eastern edge of the Project Area. The Colorado River is the source of irrigation water for agriculture in the area.

No designated critical habitat, special management areas, wilderness study areas, or Areas of Critical Environmental Concern (ACEC) are located within the solar array site or gen-tie line corridors.

Methodology

The following sections provide an overview of the biological resources evaluation methods that were used in conducting the biological resources assessment for this Project. The study area refers to the solar facility site, the gen-tie line and additional areas to be affected directly or indirectly by the proposed Project. From here on, the study area is defined as the solar facility site and a 500-foot-wide gen-tie line corridor (250 feet on each side of the gen-tie centerline).

Prior to initiating the biological surveys, available data was reviewed from resource management plans and other relevant documents to determine the locations and types of biological resources that have the potential to exist within and adjacent to the biological resources survey area. Database and literature searches included review of numerous biological databases including the California Natural Diversity Database (CDFW 2011c and 2012), California Native Plant Society Inventory (CNPS 2011), U.S. Fish and Wildlife Service (USFWS) Critical Habitat Portal (USFWS 2011a), California Gap Analysis Program (USGS 2011), and National Wetland Inventory (USFWS 2011b). A quad-based search was conducted to provide information on listed species that may occur in the vicinity and to identify potential biological resource concerns in the Project vicinity. The following USGS 7.5-minute quadrangles were reviewed, Roosevelt Mine, Ripley, McCoy Spring, McCoy Peak, McCoy Wash, Blythe NE, Blythe, Mule Wash, Palo Verde, Thumb Peak, Wiley Well, and Hopkins. These search parameters encompass an approximately 10-mile buffer around the study area. This buffer accounts for the home ranges of all species that could occur, may migrate through, or forage in the Project area. Certain species have larger home ranges, such as the golden eagle (*Aquila chrysaetos*), and their home ranges may occur primarily outside of this buffer; however, species such as these are expected to readily migrate into and out of the study area based on their habitat needs. The database search, then, was assumed to account for all species that are known to occur near the study area and that are not restricted from migrating or foraging through the study area. However, species that may have more restrictive habitat requirements or home ranges and would be

unlikely to be present near the study area based on vegetation, disturbance, soil substrates, or other factors were excluded.

Examinations of aerial photographs and other sensitive species accounts for Riverside County were also conducted. Regional resource planning documents prepared by federal, State, and local agencies were reviewed, including the California Desert Conservation Area Plan (BLM 2005), the Northern and Eastern Colorado Desert Coordinated Management Plan (BLM and CDFG 2002), the Riverside County General Plan (Riverside County 2003), and the USFWS Recovery Plan for the desert tortoise (*Gopherus agassizii*) (USFWS 2011c).

Information gathered from the literature review was used to help identify habitat for all threatened and endangered plant and wildlife species with potential to occur within the study area during the reconnaissance surveys and habitat mapping. The habitat mapping survey was conducted to assess general and dominant vegetation types, community sizes, habitat types, and species present within communities. Community types were based on observed dominant vegetation composition and density. Vegetation communities were classified based on Holland (1986), Sawyer and Keeler-Wolf (1995), and California Department of Fish and Wildlife (CDFW) classifications were used to provide additional detail when needed, such as denoting special vegetation communities that are either known or believed to be of high priority for inventory in California Natural Diversity Database (CNDDB) due to significance or rarity. Plants of uncertain identity were collected and subsequently identified from taxonomic keys (Hickman 1993) and field guides (Stuart and Sawyer 2001). Scientific and common species names were recorded according to The Jepson Manual: Higher Plants of California.

The reconnaissance survey assess the presence of a wildlife species based on direct observation, wildlife sign (e.g., tracks, burrows, nests, scat), or vocalization. Field data compiled for wildlife included the species scientific name, common name, and evidence of sign when no direct observations were made. Wildlife were identified and named based on field guides and other related literature (Burt and Grossenheider 1980; Elbroch 2003; Sibley 2000; and Stebbins 2003).

Prior to conducting focused field surveys, BLM, USFWS and the County were consulted to determine survey needs and appropriate survey time frames. Based on the habitat mapping, reconnaissance surveys and input from the wildlife agencies protocol surveys were conducted for special status plants and the burrowing owl (*Athene cunicularia hypugaea)*.

For the purposes of this document, “special-status” is being defined as species that are:

Listed, proposed for listing, or candidates for listing as threatened or endangered under the Endangered Species Act (ESA) (50 CFR Part 17.12 [listed plants], 50 CFR Part 17.11 [listed animals], 67 Federal Register [FR] 40657 [candidate species], and various notices in the FR [proposed species]]);

- Listed or proposed for listing by the State of California as threatened or endangered under the California Endangered Species Act (CESA) (CDFW 2011a);
- Identified by the California Department of Fish and Wildlife (CDFW) as species of concern or fully protected species, including fish and wildlife that do not have state or federal threatened or endangered status but may still be threatened with extinction (CDFW 2011b);
- California Species of Special Concern, vertebrate species that have been designated as “species of special concern” by the CDFW because declining population levels, limited range, and/or continuing threats have made them vulnerable to extinction (CDFW 2011b);
- On BLM land with the potential to be affected, species that are listed by the BLM as Sensitive (BLM 2010);
- Species that are listed by the California Rare Plant Ranking System (CRPR) as List 1A (presumed extirpated in California), 1B (rare, threatened, and endangered in California and elsewhere), or 2A (presumed extirpated in California, but more common elsewhere), or 2B (rare, threatened, and endangered in California, but more common elsewhere).

CRPR List 1A, 1B, 2A and 2B species are considered special-status plant species if they fall within any of these categories as defined in the Native Plant Protection Act, California Fish and Game Code (CFGC) Section 1901, or the CESA, CFGC Sections 2050 through 2098 (CNPS 2001, 2011); or

- Covered as a State-protected furbearing mammal (PFM).

The term "special-status species" excludes those avian species solely identified under Section 10 of the Migratory Bird Treaty Act (MBTA) for federal protection. Nonetheless, protected species under MBTA (50 CFR Part 10.13) are afforded avoidance and minimization measures per federal and State requirements.

Under the CEQA review process, only CRPR List 1 and 2 species are considered since these are the only CRPR species that meet CEQA's definition of "rare" or "endangered" (14 CCR §15380). Impacts to the species listed under the old ranking of CNPS List 3 and 4 are not regarded as significant pursuant to CEQA. Surveys and database and literature searches were also conducted to determine presence or of absence of resources protected by the NECO plan and burros, which are protected under the Wild Free-Roaming Horse and Burro Act (Public Law 92-195).

Results

The following sections describe the results of the biological inventory. The results reflect both the data collected from the literature, database reviews, and physical surveys conducted in the study area. Acreages provided in Table 3.2.4-1 below for the gen-tie line and its Alternatives include a 500-foot survey corridor (250 feet on either side of the centerline) in addition to the area that is part of the Project area. In comparison to the numbers below, which already include a buffer, the proposed gen-tie line by itself is 73 acres, the Northern Alternative is 95 acres, and the Southern Alternative is 60 acres.

Vegetation Communities

Eleven vegetation communities and other cover types were identified within the study area during the field surveys (Table 3.2.4-1; Figure 3.2.4-1). Vegetation communities were mapped according to the second edition of *A Manual of California Vegetation, Second Edition* (Sawyer et al. 2009). Community classifications were based on dominant species comprising approximately 50 percent or more of the total cover within the mapped unit relative to the list of dominant species for a given vegetation community.

TABLE 3.2.4-1 VEGETATION COMMUNITIES AND COVER TYPES

VEGETATION COMMUNITIES AND OTHER COVER TYPES	ACREAGE ON THE SOLAR ARRAY SITE PROJECT BOUNDARY	ACREAGE ON THE PROPOSED GEN-TIE LINE*	ACREAGE ON THE NORTHERN ALTERNATIVE GEN-TIE LINE*	ACREAGE ON THE SOUTHERN ALTERNATIVE GEN-TIE LINE*	ACREAGE ON THE REDUCED ACREAGE ALTERNATIVE SOLAR ARRAY SITE

*500-foot corridor (250 feet on either side of the gen-tie centerline) takes into account potential indirect and direct impacts to biological resources
†While Riverside County's estimate of the parcels within the solar facility is 3,587 acres, the GIS-calculated number listed in this table is 3,605.8 acres.

Bajada. Bajadas are essentially alluvial fans or desert washes. This community is present in the northeastern corner of the study area and is typically characterized as the shallow, sandy, braided bottoms of wide canyons. This community most closely resembles Holland's "Mojave Desert Wash Scrub," Code 63700 (Holland 1986).

Creosote Bush Scrub/Disturbed Creosote Scrub. Within the study area, this community is characterized by sandy soils with a shallow clay pan on a broad gentle southeast-trending slope. Dominant plants within the study area for this community include creosote bush (*Larrea tridentata*), burro bush (*Ambrosia dumosa*), brittlebush (*Encelia farinosa*), and cheesebush (*Hymenoclea salsola)*. This is the most common plant community consisting of non-agricultural plants within the study area. This plant community intergrades into the desert riparian woodland wash. Within the creosote scrub habitat in the study area, there are areas of desert pavement that are covered with rounded cobbles that range in size from one to three inches. Typically, these areas are higher than the surrounding landscape by three to 15 feet. These areas are within creosote bush scrub, though the plant density is lower. Sonoran creosote bush scrub is designated by Holland as Code 33100 and Sawyer Keeler-Wolf and Evens as the Ocotillo Series (Holland 1986; Sawyer et al. 2009).

Within the gen-tie line corridors, the creosote bush scrub is relatively undisturbed, except for occasional vehicle tracks. In these areas, fine sand drifts are interspersed within this community type; the Emory's indigo bush occurs in stands and is more prevalent than in other portions of the creosote bush scrub.

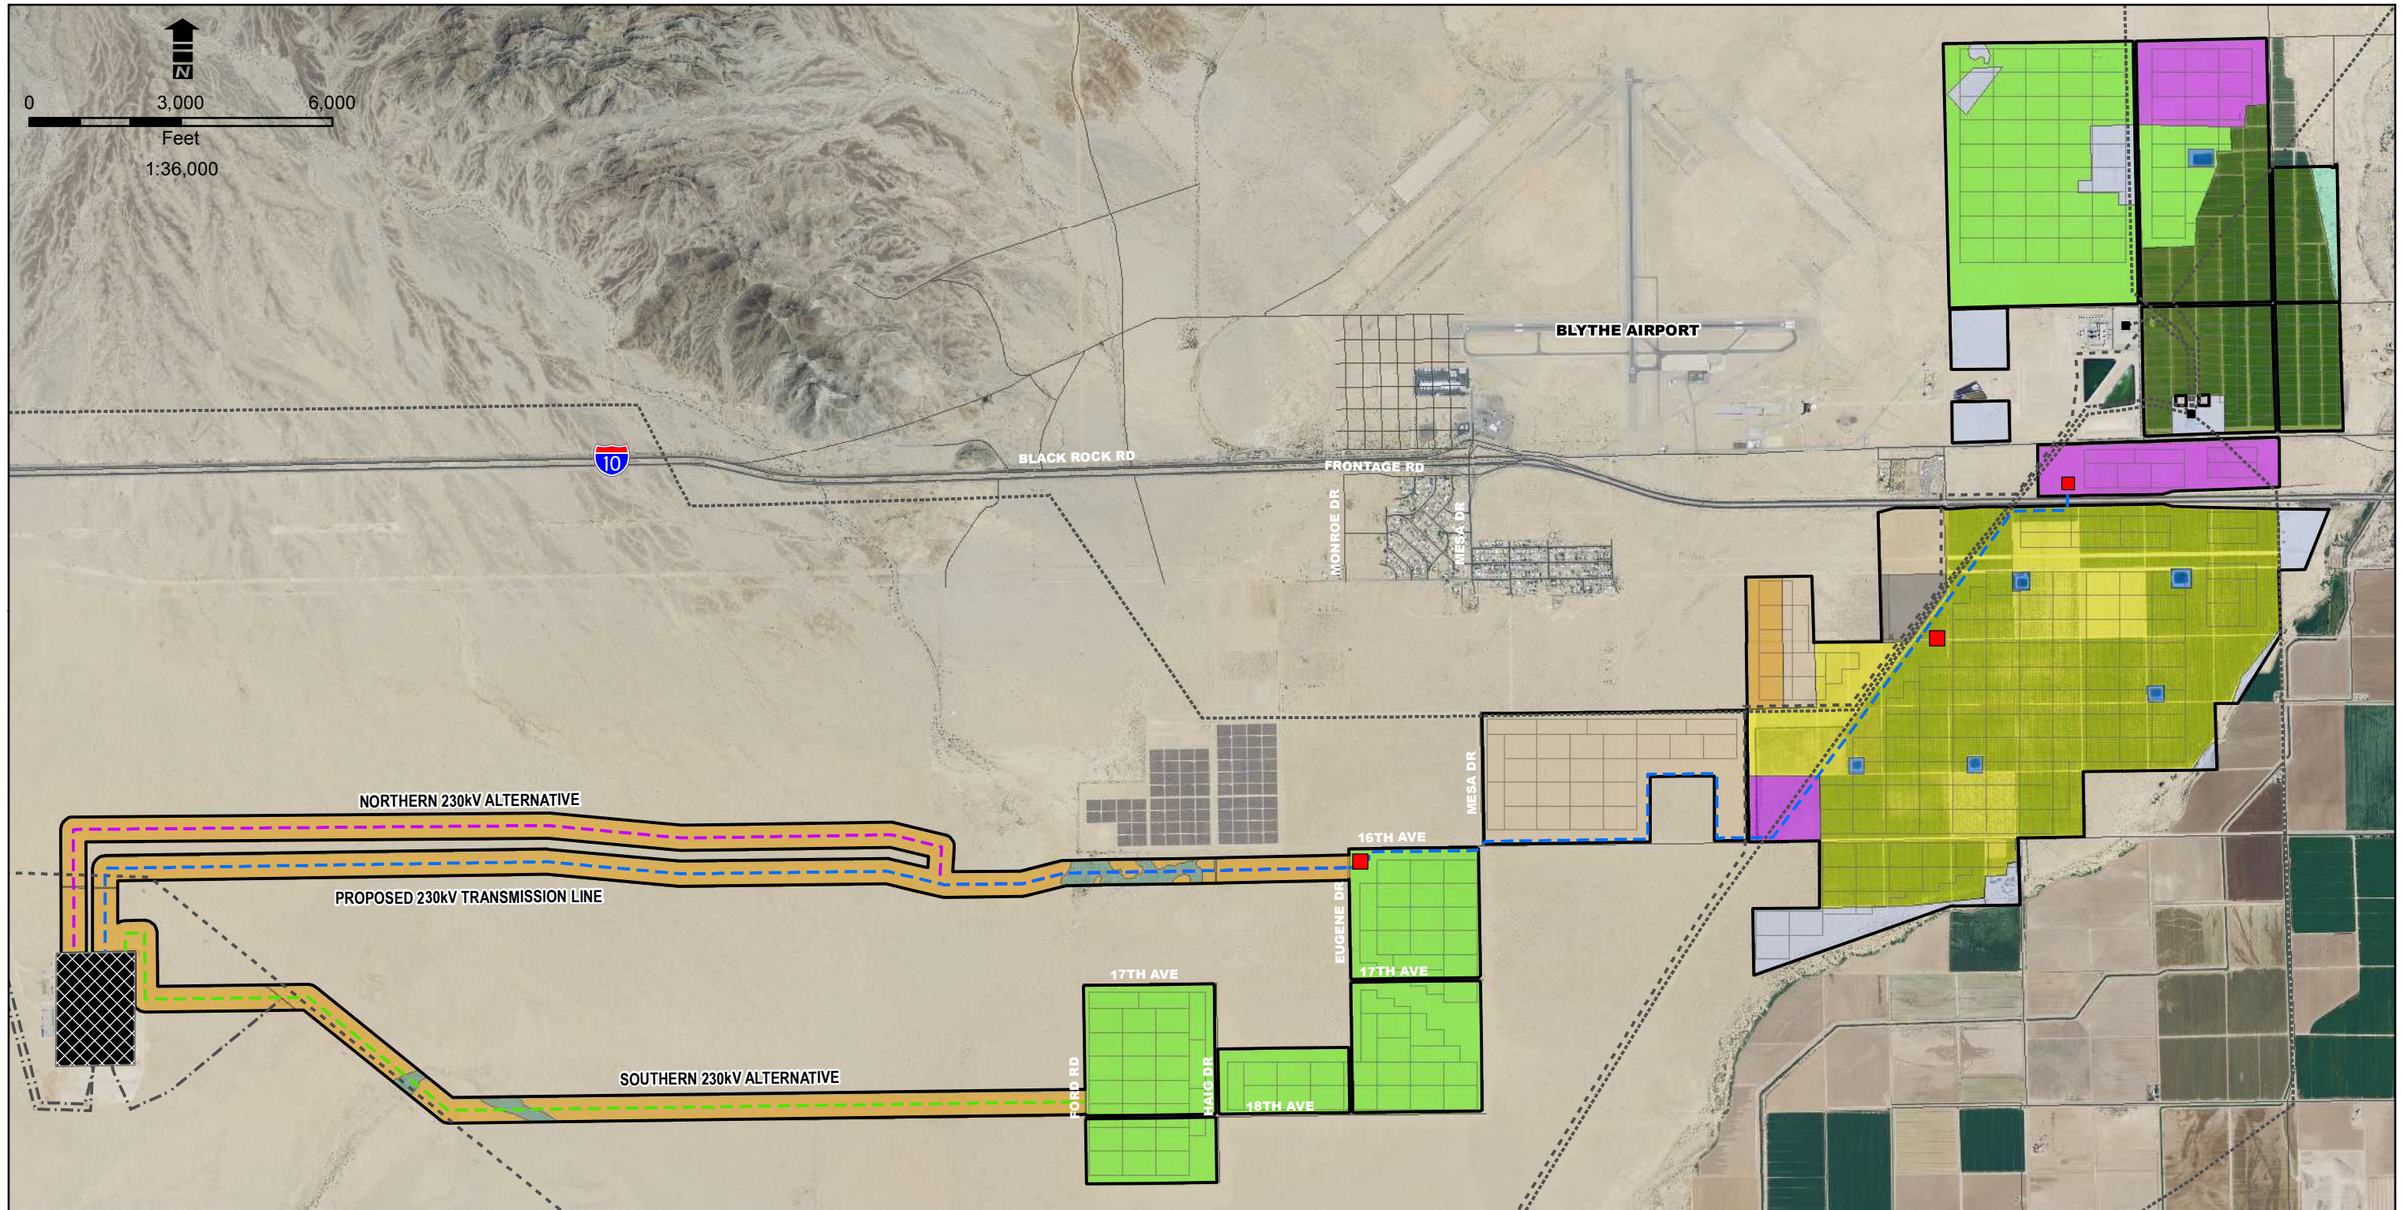
There are more areas of disturbed creosote bush scrub in the solar array area compared to the gen-tie line. Past disturbances in these areas consist of military training and agricultural use, including cultivation of jojoba (*Simmondsia chinensis*). These disturbances occurred in the past, and the Sonoran creosote bush scrub within the solar array area has been recovering through natural recruitment. Two invasive plant species, Russian thistle (*Salsola tragus*) and Sahara mustard (*Brassica tournefortii*), can be found in disturbed areas throughout the study area, especially near roads and fallow and active agricultural areas. Another exotic plant, Mediterranean grass (*Schismus* sp.), is prevalent throughout the creosote bush scrub.

Desert Riparian Woodland Wash. This vegetation community consists of open, drought-deciduous, riparian scrub woodland and is made up of three primary components: wash-dependent vegetation, vegetated ephemeral dry wash, and islands of Sonoran creosote bush scrub (e.g., riparian interfluves). Dominant and indicator plants of this community within the study area include honey mesquite (*Prosopis glandulosa*), palo verde (*Cercidium floridum*), desert ironwood (*Olneya tesota*), cat-claw acacia (*Acacia greggii*), and rush milkweed (*Asclepias subulata*). Creosote bush and burro brush were scattered throughout the canopy. The herbaceous layer is dominated by desert plantain (*Plantago ovata*), *Cryptantha* spp., and Mediterranean grass (*Schismus barbatus*). Of the vegetation communities listed in

Table 3.2.4-1, the CDFW considers desert riparian woodland wash to be a sensitive habitat/biological resource. In addition, desert riparian woodland wash is a special community type (i.e., high priority for inventory in the CNDDB) per the CDFW's Vegetation and Mapping Program. Desert riparian woodland wash is equivalent to Holland's desert dry wash woodland (Code 62200) and Sawyer, Keeler-Wolf and Evens' Catclaw Acacia Series (Holland 1986; Sawyer et al. 2009).

Irrigated Cropland/Irrigation Pond/Orchard/Jojoba/Wheat. These community types fall into the broader category of agriculture. The majority of agricultural land within the proposed solar array disturbance area is fallow and active agriculture. It includes lands that are currently under cultivation and those that are abandoned (e.g., fallow). Within abandoned agriculture areas, native vegetation is growing back; Russian thistle, Sahara mustard, and other exotic plants were observed interspersed with the native vegetation and are indicative of past agricultural disturbance.

Disturbed/Ruderal. Disturbed/Ruderal communities have been previously disturbed and have been converted to mostly non-native, weedy areas. Ruderal vegetation is that which grows quickly in disturbed areas and may consist of native species, such as fire-following plants, or non-native species, such as invasive grasses or forbs. Examples of invasive species that would occur in these areas include redstem filaree (*Erodium cicutarium*), Sahara mustard, and Mediterranean grass. Ruderal areas in the study area are primarily concentrated within the proposed solar array area.



Flora

In total, 79 plant species were detected in the Project Area during vegetation mapping, including 15 non-native plant species. Data was collected on plant species during the database search and protocol-level special-status plant surveys conducted in the Spring of 2011 (refer to the *Biological Resources Technical Report* in Appendix C1 and the *Blythe Mesa Solar Project 230 kV Transmission Line Alternative Habitat Assessment Report* in Appendix C2 of this Draft EIR/EA). It should be noted that spring 2011 was a dry year and therefore the survey data was supplemented by a records search from surrounding projects that overlapped with the study area (AECOM 2010; CH2M Hill 2010). In addition to the supplemented data conducted in wet years (2009-2010) additional pre-construction surveys shall be conducted for State and federally listed Threatened and Endangered, Proposed, Petitioned, and Candidate plants in a 250-foot radius around all areas subject to ground-disturbing activity.

Of the 79 species recorded, a total of 15 special-status plant species have potential to occur within the study area (Table 3.2.4-2). No federally listed or State-listed plant species was observed within the study area during the protocol-level surveys or during surveys that crossed the study area (POWER 2012a; CH2M Hill 2010; AECOM 2010). Two of the special-status species detected are CRPR List 1B or List 2 (rare) and therefore require consideration under CEQA: Harwood's woollystar (*Eriastrum harwoodii*) and Harwood's milkvetch (*Astragalus insularis* var. *harwoodii*). The remaining species are formally listed as CNPS List 4 (watch-list) and no longer tracked by the CRPR System; they include desert unicorn (*Proboscidea althaeifolia*) and winged cryptantha (*Cryptantha holoptera*). In addition to no longer being tracked, they are also not considered special- status by, CEQA standards, the County or by the BLM. Species accounts are provided in the Biological Technical Report for special-status plant species that occur or have potential to occur in the study area. Table 3.2.4-2 provides a summary of the special-status plant species with the potential to occur within the study area.

State-listed Plant Species. Based on site-specific habitat evaluations conducted by Project biologists and a literature and database review, including a CNDDB record search, no State-listed plant species have been recorded near the study area or have potential to occur in the study area.

Other Special-Status Plant Species. Harwood's woollystar was observed within the study area. Harwood's woollystar, a CRPR 1B.2 (rare, threatened, or endangered in California and elsewhere) species, was detected in all three Alternative gen-tie line corridors. Forty-nine individuals were observed in flower within the survey area. These individuals are displayed as point locations on Figure 3.2.4-2.

TABLE 3.2.4-2 SPECIAL-STATUS PLANT SPECIES RELEVANT TO THE PROPOSED PROJECT POTENTIALLY OCCURRING IN THE STUDY AREA

COMMON NAME SCIENTIFIC NAME	SENSITIVITY STATUS[1,3]	PLANT HABIT AND GENERAL HABITAT DESCRIPTION (CNPS 2012)	FLOWERING PERIOD (CNPS 2012)	DISCUSSION	POTENTIAL FOR OCCURRENCE WITHIN THE SOLAR ARRAY[2]	POTENTIAL FOR OCCURRENCE WITHIN THE PROPOSED GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE NORTHERN GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE SOUTHERN GEN-TIE LINE (BLM JURISDICTION)[2]
Angel trumpets (Acleisanthes longiflora)	CRPR 2.3 NECO Plan	Prostrate to ascending perennial stems less than three feet. Occurs in dry places, generally on carbonate or limestone derived soils in mountainous areas 30 to 8,000 feet.	May	The closest record of this species is in the Big Maria Mountains.	Low	Low	Low	Low
Coachella Valley Milkvetch (Astragalus lentiginosus var. coachellae)	ESA: Endangered CRPR 1B.2 BLM: Sensitive	Sonoran Desert, in sandy areas growing at elevations of 0 to 1,150 feet.	Annual or perennial herb that flowers February to May.	Habitat for this species occurs within sandy washes. Most populations are restricted to the Coachella Valley, approximately 50 miles west of the Study Area.	Low	Low	Low	Low
Harwood's milkvetch (Astragalus insularis var. harwoodii)	CRPR 2.2 NECO Plan	Annual plant. Occurs in the Sonoran Desert in sandy to gravely areas 0 to 1,000 feet.	January to May	This species was detected in the Project vicinity toward the northwestern limits in 2009 (CEC).	Moderate	High	High	High
Gravel milkvetch (Astragalus sabulonum)	CRPR 2.2	Annual and perennial herb. Occurs in desert dunes and Mojavean and Sonoran desert scrub in sandy or gravelly areas. Also in washes or along roadsides. Occurs between 195 and 3,050 feet.	February to June	The nearest CNDDB record is approximately 1.5 miles north of the Study Area in a "best guess" location.	Low	Moderate	Moderate	Moderate

COMMON NAME SCIENTIFIC NAME	SENSITIVITY STATUS[1,3]	PLANT HABIT AND GENERAL HABITAT DESCRIPTION (CNPS 2012)	FLOWERING PERIOD (CNPS 2012)	DISCUSSION	POTENTIAL FOR OCCURRENCE WITHIN THE SOLAR ARRAY[2]	POTENTIAL FOR OCCURRENCE WITHIN THE PROPOSED GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE NORTHERN GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE SOUTHERN GEN-TIE LINE (BLM JURISDICTION)[2]
Pink fairyduster (Calliandra eriophylla)	CRPR 2.3 NECO Plan	Shrubs less than one foot in height. Occurs in Sonoran Desert, sandy washes, slopes, and mesas typically between 390 and 5,000 feet.	January to March	Some suitable habitat is present. Species most often occurs at sites above 500 feet.	Low	Low	Low	Low
Saguaro (Carnegiea gigantea)	CRPR 2.2 NECO Plan	Perennial stem succulent. Occurs in Sonoran desert scrub in rocky areas, typically between 165 and 4,920 feet.	May to June	The only CNDDB record is approximately 15 miles south of the Study Area.	None	None	None	None
Crucifixion horn (Castela emoryi)	CRPR 2.3 NECO Plan	Shrub less than 10 feet in height. Occurs in Mojavean and Sonoran desert scrub on dry, gravelly washes from 295 to 3,000 feet.	April to May	This large shrub was not observed in the surveys, which were conducted within the appropriate blooming period.	None	None	None	None
Abrams' spurge (Chamaesyce abramsiana)	CRPR 2.2	Annual herb. Occurs in Mojavean and Sonoran desert scrub on sandy soils up to 3,000 feet.	September to November	37 records totaling over 2,000 individuals within a 10 mile radius recorded by CNDDB (2013). Nearest location approximately 0.6 miles north of the west end of the solar array (CNDDB EO Index 88392)	Moderate	Moderate	Moderate	Moderate
Las Animas colubrine (Colubrina californica)	CRPR 2.3 NECO Plan	Perennial, deciduous shrub generally less than three feet in height. Occurs in Sonoran creosote bush scrub less than 3,500 feet.	April to June	According to CEC 2009 data, specimens were observed in flower during April, an early blooming period for this species. Similar habitat is expected to occur in the Study Area.	Low	Moderate	Moderate	Moderate

COMMON NAME SCIENTIFIC NAME	SENSITIVITY STATUS[1,3]	PLANT HABIT AND GENERAL HABITAT DESCRIPTION (CNPS 2012)	FLOWERING PERIOD (CNPS 2012)	DISCUSSION	POTENTIAL FOR OCCURRENCE WITHIN THE SOLAR ARRAY[2]	POTENTIAL FOR OCCURRENCE WITHIN THE PROPOSED GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE NORTHERN GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE SOUTHERN GEN-TIE LINE (BLM JURISDICTION)[2]
Harwood's woollystar (Eriastrum harwoodii)	CRPR 1B.2 BLM: Sensitive	Annual herb. Occurs in desert dunes and Sonoran Desert scrub on sandy soils from 400 to 3,000 feet.	March to June	Observed in abundance in an area between the northern and southern alternatives in 2011. Not observed in 2012 possibly due to below average precipitation.	Low	Present	Present	Present
Bitter hymenoxys (Hymenoxys odorata)	CRPR 2	Annual herb. Occurs in chaparral, coastal scrub, Mojavean Desert scrub, and meadows and seeps, often in alkali soils, and riparian scrub with mesic soils. Most often found on sandy sites from 145 to 490 feet.	February to November	Habitat for this species is limited to the desert riparian woodland wash located in the easternmost portion of the proposed transmission line.	Low	Low	Low	Low
California satintail (Imperata brevifolia)	CRPR 2.1	Perennial grass. Occurs in San Bernardino Mountains and Mojave Desert in cultivation. Found near wet springs, meadows, stream sides and flood plains up to 1,700 feet.	September to May	The habitat for this species (wet springs, meadows, stream sides, and flood plains) does not occur within the Study Area.	None	Low	Low	Low
Darlington's blazing star (Mentzelia puberula)	CRPR 2.2	Perennial herb. Occurs in sandy or rocky areas of Mojavean and Sonoran desert scrub, between 295 and 4,200 feet.	March to May	The only CNDDB record is approximately 14.5 miles south of the Study Area.	Low	Low	Low	Low
Orocopia sage (Salvia greatae)	CRPR 1B.3 NECO Plan	Southeast Sonoran Desert (Orocopia, Chocolate Mtns.) on alluvial slopes between 100 to 800 feet.	Evergreen shrubs less than 3 feet in height with white blooms from March to April.	Nearest known occurrence near Desert Center, 35 miles west of the Project.	Low	Low	Low	Low

COMMON NAME SCIENTIFIC NAME	SENSITIVITY STATUS[1,3]	PLANT HABIT AND GENERAL HABITAT DESCRIPTION (CNPS 2012)	FLOWERING PERIOD (CNPS 2012)	DISCUSSION	POTENTIAL FOR OCCURRENCE WITHIN THE SOLAR ARRAY[2]	POTENTIAL FOR OCCURRENCE WITHIN THE PROPOSED GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE NORTHERN GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE SOUTHERN GEN-TIE LINE (BLM JURISDICTION)[2]
Desert spikemoss (Selaginella eremophila)	CRPR 2.2	Eastern Peninsular Ranges to the Sonoran Desert at elevations less than 3,000 feet. Shaded sites among rocks, in crevices and gravelly soils.	Rhizomatous mat-forming non-flowering herb.	The habitat for this species (shaded gravel soil in crevices and rocks) is limited in the Study Area.	Low	Low	Low	Low
Dwarf germander (Teucrium cubense ssp. depressum)	CRPR 2.2	Annual plant up to six inches tall. Occurs in sandy soils, washes, and fields in the Sonoran Desert below 1,200 feet.	March to November	Habitat for this species is present within the Study Area and vicinity.	Low	High	High	Moderate
Jackass clover (Wislizenia refracta ssp. refracta)	CRPR 2.2 NECO Plan	Sandy washes, roadsides, alkaline flats in the Mojave Desert, and northern Sonoran Desert between 1,600 to 2,000 feet.	Annual; flowers between April and November.	Habitat is not present based on elevation criteria.	None	None	None	None
Orcutt's woodyaster (Xylorhiza orcuttii)	CRPR 1B.2 BLM Sensitive	Arid canyons between 60 and 1,000 feet.	Shrubs less than 5 feet in height; blooms March to April.	According to CEC data, one plant recorded north of the San Diego / Imperial County border in Indio (Riverside County).	Low	Low	Low	Low

[1]Sensitivity Status Key
ESA Federal Endangered Species Act
CRPR California Rare Plant Rank
1A: Plants presumed extirpated in California and either rare or extinct elsewhere.
1B: Considered rare, threatened, or endangered in California and elsewhere.
2A: Plants presumed extirpated in California, but more common elsewhere
2B: Plants Rare, Threatened, or Endangered in California, But More Common Elsewhere
Threat Ranks/ Decimal notations: ACNPS extension added to the CRPR
- Seriously threatened in California (over 80% of occurrences threatened / high degree and immediacy of threat)
- Moderately threatened in California (20-80% occurrences threatened / moderate degree and immediacy of threat)
– Not very threatened in California (<20% of occurrences threatened / low degree and immediacy of threat or no current threats known)

[2]Species Potential for Occurrence
Low Potential – low potential to occur because suitable habitat is of marginal quality.
Moderate Potential – has moderate potential to occur because suitable habitat was expected to be present but was not found during focused plant surveys
High Potential – has high potential to occur because suitable habitat was expected to be present, and species is known to occur within the vicinity but was not found during focused plant surveys
Present – detected during surveys or recorded in previous surveys

[3]Only CRPR 1 and 2 are included in the rare plant table for Blythe Mesa
BLM Sensitive Plants: plant species found on public lands administered by the Bureau of Land Management whose survival is of concern due to limited distribution, low number of individuals and/or populations, and potential threats to habitat.
NECO Plan: Northern and Eastern Colorado Desert Coordinated Management Plan special-status species

Based on a CNDDB search, Harwood's milk-vetch (*Astragalus insularis* var. *harwoodii*), a CNDDB List 2.2 species, has a high potential to occur within the proposed gen-tie line disturbance area. Additional species have lower potentials to occur as reflected in Table 3.2.4-2. There are numerous records in the vicinity and several that are just outside the survey corridor area. Ribbed cryptantha and winged cryptantha are both CNPS List 4.3 and were detected within the study area. Both species are not discussed in detail and are not considered special-status due to being on CNPS List 4.3; refer to the methodology section for a description of special-status species.

Fauna

In total, 57 wildlife species were detected during general reconnaissance and protocol wildlife surveys (refer to the biological resources technical reports in Appendix C1 and C2 of this Draft EIR/EA), as well as reported in the database search. Of the wildlife species detected during the survey work and literature review, seven special-status wildlife species or their sign were observed within the study area (Table 3.2.4-3), including Mojave fringe-toed lizard (*Uma scoparia*) (Figure 3.2.4-4), western burrowing owl (*Athene cunicularia hypugaea*), Le Conte's thrasher *(Toxostoma lecontei*), loggerhead shrike (*Lanius ludovicianus*), Nelson's bighorn sheep (*Ovis canadensis nelson*), American badger (*Taxidea taxus*), and desert kit fox *(Vulpes macrotis arsipus*). In total, 11 insect, nine reptile, 28 bird, and nine mammal species were detected during biological surveys. Figure 3.2.4-3 illustrates the special-status wildlife inventory results.

Wildlife species observed during the reconnaissance and focused surveys conducted for this Project are listed in the Biological Technical Report. The species most commonly observed during biological surveys included lizards, such as the common side-blotched lizard (*Uta stansburiana*), desert iguana (*Dipsosaurus dorsalis*), and western whiptail (*Aspidoscelis tigris*), along with desert ironclad beetle (*Asbolus verrucosus*), common raven (*Corvus corax*), great-tailed grackle (*Quiscalus mexicanus*), and white-tailed antelope squirrel (Ammospermophilus leucurus). Species accounts are provided in the *Biological Resources Technical Report* and the *230 kV Transmission Line Alternatives Habitat Assessment Report* (Appendix C1 and C2, respectively) for the special-status species that could occur within the study area. This includes species that both were and were not detected during surveys. Razorback sucker, while federally- and State-listed with a record in CNDDB (CDFW 2011a), is expected to be absent due to a lack of habitat within the study area and is not discussed. Table 3.2.4-3 provides a summary of the species accounts and potential to occur.

Federally Listed Wildlife Species

No federally listed wildlife species were detected within the study area during spring 2011 or 2012 survey work. However, despite no detection during the survey effort there is a moderate potential for one federally listed threatened wildlife species, the desert tortoise (Gopherus agassizii), to occur within Alternatives 1, 3, and 5. The moderate potential is based on consultation with USFWS and review of surrounding Project data and a CNDDB records search (USFWS 2012; CDFW 2012a). Along Alternative 4 the species has a high potential to occur based on existing records, sign and potential habitat that was found to support the desert tortoise during the survey effort (POWER 2012a, POWER 2012b, CDFW 2013).

State-listed Wildlife Species

No State-listed wildlife species were detected within the study area during spring 2011 or 2012 survey work. There is a potential for the Swainson's hawk (*Buteo swainsoni*) to forage within the study area; however, the species was not detected during the survey effort. Based on existing records and potential habitat, Alternative 4 has the potential to support the desert tortoise. Based on existing records and potential habitat, Alternative 4 has the potential to support the desert tortoise.

Non-listed Special-Status Wildlife Species

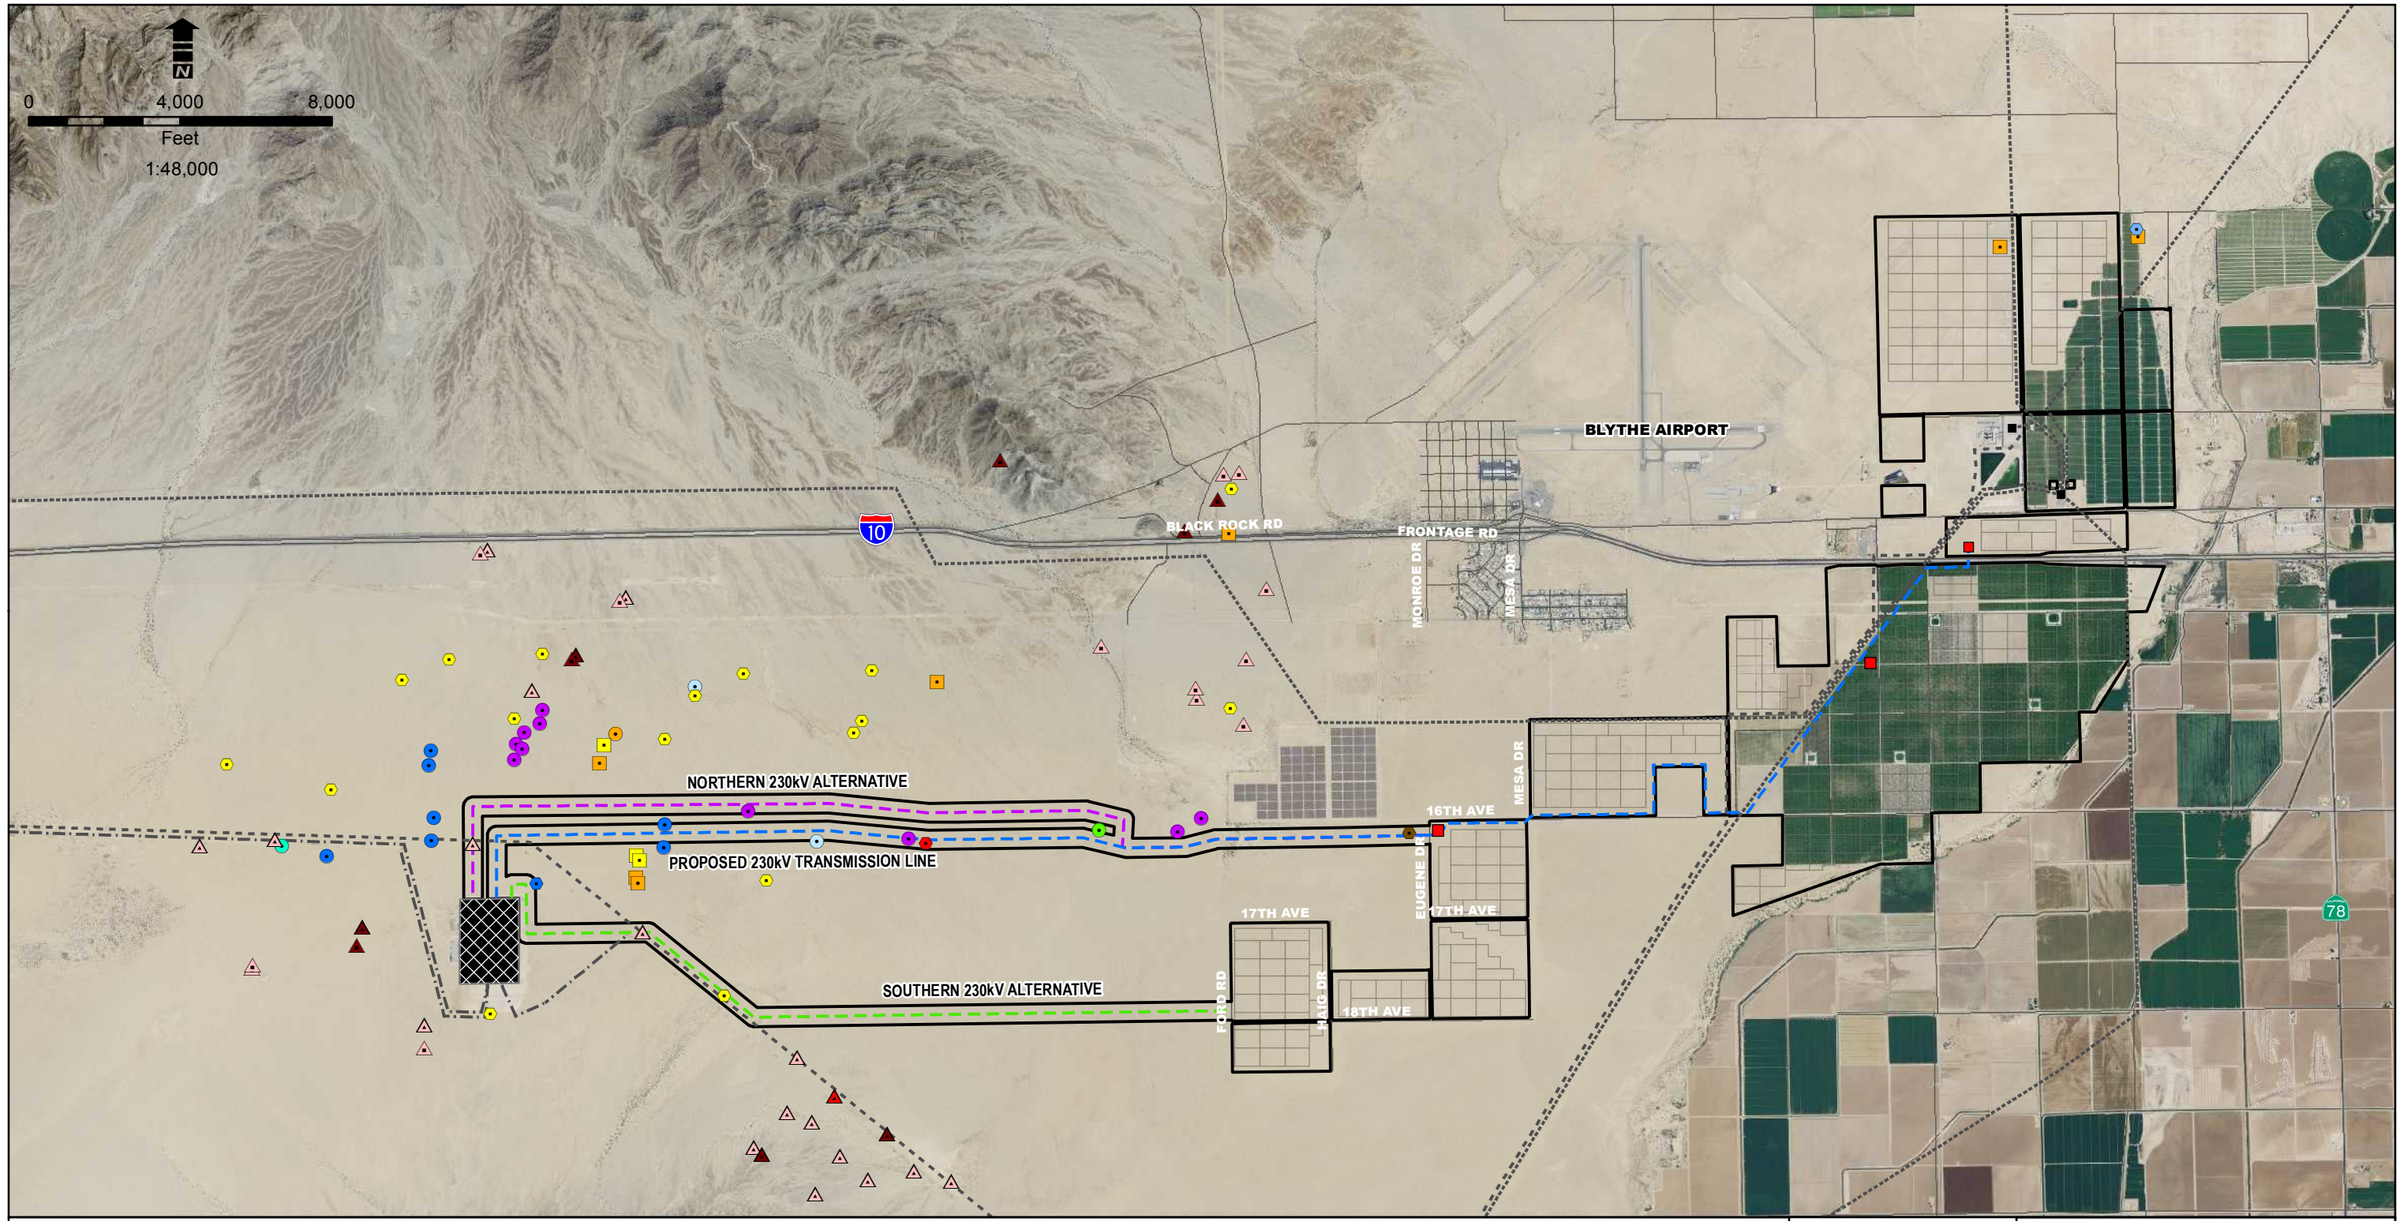
Seven non-listed special-status wildlife species or their sign were detected on-site, including the Mojave fringe-toed lizard, western burrowing owl, Le Conte's thrasher, loggerhead shrike, desert kit fox, Nelson's

bighorn sheep, and American badger. These detections are discussed in detail in the biological resources technical reports (Appendix C1 and C2, respectively).

The golden eagle (*Aquila chrysaetos*) is a CDFW Fully Protected Species and Watch List Species and a USFWS Bird of Conservation Concern. Golden eagles or their nests were not observed during surveys for this Project and there are no known golden eagle nests in the general vicinity of the Project area (AECOM 2010; Tetra Tech 2011). The golden eagle does not have any nesting habitat within the study area and there are no active nests known to be present within 10 miles (CDFW 2013). However, abundant foraging habitat is present in and around the study area, particularly south of I-10, and it may enter into the study area while foraging away from its nesting sites.

Jurisdictional Waters

A hydrology study was performed in 2012 to review potential jurisdictional waters (provided in Appendix C5, *Review of Federal Waters,* of this Draft EIR/EA). POWER found that there are two discontinuous ephemeral channels within the Project area. The discontinuous ephemeral channels consist of swales and erosional features including gullies and potential small washes characterized by low volume, infrequent or short duration flow. Based on the data collected the two discontinuous ephemeral channels are considered potential federal waters. For additional discussion on jurisdictional waters, refer to Section 3.2.9, Hydrology and Water Quality. There are 29.2 acres of Desert Riparian Woodland Wash, considered potential waters of the State (POWER 2012a). There is an agricultural irrigation ditch running close to the eastern edge of the proposed solar array, but it does not cross the study area and is approximately 75 to 90 feet below the edge of the study area. There are several palustrine open-water wetlands, likely stock ponds, located in a block in an area that is surrounded by the Project east of the Blythe Airport and north of I-10, but there are no palustrine open-water wetlands within the Project boundaries.



Wildlife Movement

The solar array site and gen-tie line corridors could be used by a variety of wildlife species for movement purposes. Wildlife movement activities typically fall into one of three movement categories: 1) dispersal (e.g., juvenile animals from natal areas, or individuals extending range distributions); 2) seasonal migration; and 3) movements related to home range activities (foraging for food or water, defending territories, or searching for mates, breeding areas, or cover).

Local movement for wildlife across the proposed solar array site and gen-tie line corridors is currently limited by the existing agriculture use and paralleling existing transmission lines. Habitat exists outside of both the solar array site and gen-tie line corridors that would facilitate movement around the site for species.

Critical and Designated Habitat

The study area does not include any designated critical habitat for special-status plant or wildlife species. The Chuckwalla Unit, an area of designated critical habitat for the desert tortoise (59 FR 5820, 5866), is approximately 15 miles west of the study area. The NECO Plan addresses conservation of the bighorn sheep through the designation of Bighorn Sheep wildlife-habitat management areas. The two closest Bighorn Sheep wildlife-habitat management areas, McCoy Mountains and Mule Mountains, are currently listed as unoccupied range (BLM and CDFG 2002). No special management areas, wilderness study areas, or ACECs are located within the solar array site or gen-tie line corridors.

TABLE 3.2.4-3 SPECIAL-STATUS WILDLIFE SPECIES WITH THE POTENTIAL TO OCCUR IN THE STUDY AREA

COMMON NAME SCIENTIFIC NAME	SENSITIVITY STATUS[1]	HABITAT REQUIREMENTS	DISCUSSION	POTENTIAL FOR OCCURRENCE WITHIN THE SOLAR ARRAY PROJECT BOUNDARY[2]	POTENTIAL FOR OCCURRENCE WITHIN THE PROPOSED GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE NORTHERN GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE SOUTHERN GEN-TIE LINE (BLM JURISDICTION)[2]
Amphibians							
Couch's spadefoot toad (*Scaphiopus couchii*)	CDFW: Species of Special Concern BLM: Sensitive NECO Plan	Various arid and semiarid environments. Breeds in desert ponds quickly following rainfall.	Suitable habitat is not known to be present, but some areas may still support ponded water after rain events. There is a 2012 CNDDB record located approximately three miles southwest of the Colorado River Substation (CDFW 2013).	Low	Low	Low	Low
Reptiles							
Desert tortoise (*Gopherus agassizii*)	ESA: Threatened CESA: Threatened NECO Plan	Various desert scrubs and desert washes up to about 5,000 feet, but not including playas.	Desert tortoise was documented approximately 0.5 mile south of the southern alignment (CH2M Hill 2010) and sign was scattered around the Colorado River Substation (AECOM 2010). There was a high number of desert tortoise sightings in 2011 and 2012 in the washes spreading out from Mule Mountain, south of the Colorado River Substation (CDFW 2013). POWER walked transects along both alternatives in suitable habitat but did not observe desert tortoise or its sign.	Low	Moderate	Moderate	High
Mojave fringe-toed lizard (*Uma scoparia*)	CDFW: Species of Special Concern BLM: Sensitive NECO Plan	Fine, wind-blown sand in creosote bush scrub of the Mojave and northern Colorado Deserts. From below sea level to 2,952 feet.	Species detected in the northern alternative and proposed gen-tie line during habitat mapping. This species was detected in 2011 within 50 feet of the southern alternative's survey corridor (CDFW 2013).	High	Present	Present	Present

COMMON NAME SCIENTIFIC NAME	SENSITIVITY STATUS[1]	HABITAT REQUIREMENTS	DISCUSSION	POTENTIAL FOR OCCURRENCE WITHIN THE SOLAR ARRAY PROJECT BOUNDARY[2]	POTENTIAL FOR OCCURRENCE WITHIN THE PROPOSED GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE NORTHERN GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE SOUTHERN GEN-TIE LINE (BLM JURISDICTION)[2]
Birds							
Western burrowing owl (*Athene cunicularia hypugaea*)	CDFW: Species of Special Concern BLM: Sensitive USFWS: Bird of Conservation Concern NECO Plan	Found mainly in grassland and open scrub from the seashore to foothills. Also found in deserts and scrublands.	Habitat marginally suitable for this species within the gen-tie line corridors. May be occasionally present as foragers but unlikely to be present as residents. Suitable habitat and the species were detected within the solar array site during the survey work. High number of sightings in the general region (AECOM 2010, CDFW 2013).	Present	Moderate	Moderate	Moderate
Golden Eagle (*Aquila chrysaetos)*	CDFW: Fully Protected Species USFWS: Bird of Conservation Concern	Golden Eagles favor partially or completely open country, especially around mountains, hills, and cliffs. Also found in desert, shrublands, grasslands, farmland, and areas along rivers and streams.	The golden eagle does not have any nesting habitat within the study area and there are no active nests known to be present within 10 miles (AECOM 2010, Tetra Tech 2011, CDFW 2013). However, abundant foraging habitat is present in and around the study area, particularly south of I-10, and it may enter into the study area while foraging away from its nesting sites.	Low (foraging only)	Low (foraging only)	Low (foraging only)	Low (foraging only)
Ferruginous hawk (*Buteo regalis*)	CDFW: Watch List (wintering)	Open country, primarily plains, prairies, badlands, sagebrush, shrubland, desert.	The species is known to winter in the Colorado River Valley. They are most often seen in agricultural fields around Blythe, but occasionally in the open desert as well. There is no breeding habitat on-site. This species was detected just north of the northern gen-tie line during surveys for the Blythe Mesa Solar Project (AECOM 2010).	Low (non-breeding only)	Present (non-breeding only)	Present (non-breeding only)	Present (non-breeding only)

Swainson's hawk (*Buteo swainsoni*)	CESA: Threatened, USFWS: Bird of Conservation Concern, USFS: Sensitive	Nesting habitat consists of open habitats with trees, either isolated, scattered or in windrows.	Migrants more frequently occur near western edge of desert such as Borrego and Morongo valleys, as reflected in annual data from the various regional hawk-watch reports. No suitable breeding habitat exists on-site. However, this species was detected just north of the northern gen-tie line during surveys for the Blythe Mesa Solar Project (AECOM 2010).	Low (non-breeding only) High (foraging)	Present (non-breeding only) High(foraging)	Present (non-breeding only) High (foraging)	Present (non-breeding only) High(foraging)
Northern harrier (*Circus cyaneus*)	CDFW: Species of Special Concern	Typically occurs in grasslands around coastal salt or freshwater marshes. Nests are constructed on the ground in shrubby vegetation, usually near the edges of marshes.	This species was not detected during Project surveys but was detected in and around the Project during surveys for the Blythe Mesa Solar Project (AECOM 2010). There is foraging habitat around the transmission line alternatives but limited or no nesting habitat. The solar array presents limited habitat, as it consists of large cleared areas or areas with sparse vegetation.	Low	Present	Present	High
Western yellow-billed cuckoo (*Coccyzus americanus occidentalis*)	ESA: Candidate CESA: Endangered USFWS: Bird of Conservation Concern	Nests along large river systems, typically in areas dominated by willows and cottonwoods.	No suitable habitat observed in study area. Records in the vicinity of the Colorado River (CDFW 2013).	None	None	None	None

Sonoran yellow warbler (*Dendroica petechia sonorana*)	CDFW: Species of Special Concern USFWS: Bird of Conservation Concern NECO Plan	Occurs in riparian deciduous habitat, such as cottonwood and willow areas, nesting in understories. Summer resident of the Colorado River Valley.	The only suitable habitat for this species is close to where the proposed and northern gen-tie alternatives diverge, where there is a desert dry wash woodland. Historic records located around the Colorado River (CDFW 2013). This species was detected in a wash adjacent to the proposed and northern gen-tie alternatives in 2011 (Tetra Tech 2011a).	None	Present	Present	None
Southwestern willow flycatcher (*Empidonax traillii extimus*)	ESA: Endangered CESA: Endangered NECO Plan	Riparian woodlands.	No suitable habitat observed in study area. Records in the vicinity of the Colorado River (CDFW 2013).	None	None	None	None
Yellow-breasted chat (*Icteria virens*)	CDFW: Species of Special Concern	Inhabits riparian willow thickets near watercourses. Nests in low, dense riparian areas. Summer resident.	No suitable habitat observed in study area. Records in the vicinity of the Colorado River (CDFW 2013).	None	None	None	None
Loggerhead shrike (*Lanius ludovicianus*)	CDFW: Species of Special Concern USFWS: Bird of Conservation Concern	Occurs in semi-open country with utility posts, wires, and trees to perch on.	Pair detected just north of the northern alternative. This species was detected in 2012 just west of the Colorado River Substation, approximately 0.75 mile from the southern alternative (CDFW 2013), and in 2010 in areas overlapping all three gen-tie line boundaries (AECOM 2010).	High	Present	Present	Present
Gila woodpecker (*Melanerpes uropygialis*)	CESA: Endangered USFWS: Bird of Conservation Concern NECO Plan	Nests in cottonwoods or other desert riparian trees, shade trees, or date palms.	Limited suitable habitat available in the study area. Nearest occupied habitat is near Blythe on the Colorado River.	Low	Low	Low	Low

Gila woodpecker (*Melanerpes uropygialis*)	CESA: Endangered, USFWS: Bird of Conservation Concern	Requires live tree-size cactus or dead trees (Winkler et al. 1995).	Nearest occupied habitat is near Blythe on the Colorado River.	Low	Low	Low	Low
Elf owl (*Micrathene whitneyi*)	CESA: Endangered USFWS: Bird of Conservation Concern NECO Plan	In California, nests only in cottonwood-willow and mesquite riparian areas along the Colorado River.	No suitable nesting habitat in study area. May forage in or near the study area. Historic records along the Colorado River (CDFW 2013).	Low	Low	Low	Low
Summer tanager (*Piranga rubra*)	CDFW: Species of Special Concern	Requires cottonwood-willow riparian forests for nesting and foraging. Summer resident on the Colorado River.	No suitable habitat present in the study area. Historic records along the Colorado River (CDFW 2013).	None	None	None	None
Vermilion flycatcher (*Pyrocephalus rubinus*)	CDFW: Species of Special Concern NECO Plan	Open farmlands, shrubby grasslands, streamsides, and small wooded ponds in desert habitat. Found in diverse areas near open water.	Limited suitable habitat within the proposed alternatives. No recent records. Closest record is from 1919, approximately 2.2 miles away (CDFW 2013).	Moderate	Low	Low	Low
Yuma clapper rail (*Rallus longirostris yumanensis*)	ESA: Endangered CESA: Threatened CDFW: Fully Protected	Nests in freshwater marshes surrounded by tules and cattails. Found along the Colorado River.	No suitable habitat within the study area. Local occurrences primarily constrained to the Colorado River (CDFW 2013).	None	None	None	None

COMMON NAME SCIENTIFIC NAME	SENSITIVITY STATUS[1]	HABITAT REQUIREMENTS	DISCUSSION	POTENTIAL FOR OCCURRENCE WITHIN THE SOLAR ARRAY PROJECT BOUNDARY[2]	POTENTIAL FOR OCCURRENCE WITHIN THE PROPOSED GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE NORTHERN GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE SOUTHERN GEN-TIE LINE (BLM JURISDICTION)[2]
Crissal thrasher (*Toxostoma crissale*)	CDFW: Species of Special Concern NECO Plan	Occurs in dense riparian and mesquite scrub, microphyll woodland, and riparian washes with a dense understory of shrubs	Some habitat present that could support species foraging but not typical for nesting. Riparian wash present south of the southern alternative. An unidentified thrasher was heard calling during the survey on the northern alternative. This species was identified in 2012 within 500 feet of the southern alignment centerline (CDFW 2013).	Low	Moderate	Moderate	Present
Le Conte's thrasher (*Toxostoma lecontei*)	USFWS: Bird of Conservation Concern NECO Plan	Arid and open plains that are sparsely vegetated and dominated by saltbush and creosote bush	This species was previously detected in 2011 in an area between the northern and southern alternatives. Suitable habitat for this species is present mainly in the creosote bush areas of the Project. An unidentified thrasher was heard calling during the survey on the northern alternative. This species was identified in 2012 west of the Colorado River Substation within one mile of all three alternatives (CDFW 2013).	High	Present	Present	Present
Arizona bell's vireo (*Vireo bellii arizonae*)	CESA: Endangered USFWS: Bird of Conservation Concern	Summer resident along the Colorado River. Nests in willow, mesquite, or small trees and shrubs, but typically in willow thickets with an understory of marsh baccharis.	No suitable habitat present in the study area. Recent (2012) record along the Colorado River (CDFW 2013).	None	None	None	None
Yellow-headed blackbird (*Xanthocephalus xanthocephalus*)	CDFW: Species of Special Concern	Nests along the borders of lakes, ponds, or freshwater marshes and wetlands. Found in areas of dense vegetation.	This species was detected several times by POWER in 2013 within three miles of the solar array during surveys of the adjacent Palo Verde Mesa Solar Project. It has a high potential to occur in any vegetated wet basins in the area.	High	Low	Low	Low

Mammals							
Pallid bat (*Antrozous pallidus*)	CDFW: Species of Special Concern BLM: Sensitive NECO Plan	This gregarious species usually roosts in small colonies in rock crevices and buildings, but may nest in caves, mines, rock piles, and tree cavities.	Roosting habitat for pallid bats is present in tree cavities in desert riparian woodland wash in the southeastern portion of the survey area. The closest documented occurrence in the CNDDB is from 1992, approximately 30 miles to the southwest of the airport near Corn Springs. The only CNDDB records within 10 miles are both from 1919 (CDFW 2013).	Low	Low	Low	Low
Burro (*Equus asinus)*	BLM: Wildlife Free Roaming Horse and Burro Act	This species is found in the vicinity of the Colorado River, below 7,800 ft. Habitats include sagebrush, bitterbrush, Joshua tree, and pinyon-juniper.	Potential habitat is not documented within the study area, although south of the Project area BLM has documented a BLM Herd Area (HA) where species are known to roam. The HA is approximately 3 miles south of the study area.	Low	Low	Low	Moderate
Pallid San Diego pocket mouse (*Chaetodipus fallax pallidus*)	CDFW: Species of Special Concern	Along desert borders in eastern San Diego County in desert washes, desert scrub, desert succulent scrub, and pinyon-juniper areas. Usually in rocky or gravelly areas.	Very little habitat observed within the study area. Closest CNDDB occurrence is from 1957 approximately 11 miles southwest (CDFW 2013).	Low	Low	Low	Low
Townsend's big-eared bat (*Corynorhinus townsendii*)	CDFW: Species of Special Concern BLM: Sensitive NECO Plan	Occurs in a wide variety of habitats but most commonly in mesic areas. Roosts in open areas.	Suitable foraging habitat within the study area but limited roosting habitat. The closest CNDDB record is from 1919 and is approximately seven miles southeast of the surveyed areas (CDFW 2013).	Low	Low	Low	Low

COMMON NAME SCIENTIFIC NAME	SENSITIVITY STATUS[1]	HABITAT REQUIREMENTS	DISCUSSION	POTENTIAL FOR OCCURRENCE WITHIN THE SOLAR ARRAY PROJECT BOUNDARY[2]	POTENTIAL FOR OCCURRENCE WITHIN THE PROPOSED GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE NORTHERN GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE SOUTHERN GEN-TIE LINE (BLM JURISDICTION)[2]
Western yellow bat (*Lasiurus xanthinus*)	CDFW: Species of Special Concern	Occurs in valley foothill riparian, desert riparian, desert wash, and palm oasis habitats. Roosts in trees and forages over water and in trees.	Limited roosting habitat available in the study area; no water observed during surveys. The only CNDDB record is from 1980 and is mapped in Blythe.	Low	Low	Low	Low
California leaf-nosed bat (*Macrotus californicus*)	CDFW: Species of Special Concern BLM: Sensitive NECO Plan	Lowland desert scrub, desert riparian and wash areas, alkali scrub, or palm oases. Requires rugged or rocky terrain with mines or caves for roosting.	Suitable foraging habitat is present throughout the study area, although roosting habitat is limited in the immediate region, due to lack of a rugged or rocky terrain. A 2002 CNDDB record lists a colony of bats in the general vicinity (in the Roosevelt Mine quad), but specific location information is suppressed and it is unclear which species of bat may be present.	Low	Low	Low	Low
Arizona myotis (*Myotis occultus*)	CDFW: Species of Special Concern	Lowlands of the Colorado River and adjacent desert mountain ranges. Roosts in tree hollows, rock crevices, and similar areas.	The closest documented occurrence in the CNDDB is from 1942, approximately five miles south of the Project (CDFW 2013).	Low	Low	Low	Low
Cave myotis (*Myotis velifer*)	CDFW: Species of Special Concern BLM: Sensitive NECO Plan	Low elevation arid regions near the Colorado River and in adjacent mountains. Requires caves or mines for roosting.	Suitable foraging habitat is present throughout the study area, although roosting habitat is limited in the immediate region. A 2002 CNDDB record lists a colony of bats in the general vicinity (in the Roosevelt Mine quad), but specific location information is suppressed and it is unclear which species of bat may be present (CDFW 2013).	Low	Low	Low	Low

COMMON NAME SCIENTIFIC NAME	SENSITIVITY STATUS[1]	HABITAT REQUIREMENTS	DISCUSSION	POTENTIAL FOR OCCURRENCE WITHIN THE SOLAR ARRAY PROJECT BOUNDARY[2]	POTENTIAL FOR OCCURRENCE WITHIN THE PROPOSED GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE NORTHERN GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE SOUTHERN GEN-TIE LINE (BLM JURISDICTION)[2]
Yuma myotis (*Myotis yumanensis*)	BLM: Sensitive	Prefers open forests and woodlands. Requires water for foraging. Roosts in mines, caves, buildings, and crevices.	No roosting or foraging habitat available within the study area. Local CNDDB records are on the Colorado River (CDFW 2013).	None	None	None	None
Colorado Valley woodrat (*Neotoma albigula venusta*)	NECO Plan	Low-lying deserts in southeastern California, particularly those with beavertail cactus (*Opuntia basilaris*) and mesquite (*Prosopis* sp.).	While there is ample foraging habitat for this species, there is very little rocky habitat for constructing middens into. There were no obvious signs of woodrat at the burrows that were observed. The closest CNDDB record is from 1919, approximately 2.25 miles east of the solar array (CDFW 2013).	Low	Low	Low	Low
Pocketed free-tailed bat (*Nyctinomops femorosaccus*)	CDFW: Species of Special Concern NECO Plan	Occurs in rocky areas with high cliffs in pine-juniper woodland, desert scrub, palm oasis, desert wash, and desert riparian habitat.	No suitable habitat in study area.	None	None	None	None
Nelson's bighorn sheep (*Ovis canadensis nelson*)	BLM: Sensitive NECO Plan	Mountain slopes with sparse growth of trees above the desert floor in California.	Nelson's bighorn sheep is known within the region. While the species is generally associated with mountainous areas, desert floor areas are important for dispersal and seasonal movement. However, no records were found within the study area. In addition, the survey work conducted in 2011 and 2012 did not detect the species or sign that it utilizes this area.	Low	Low	Low	Low
Colorado River cotton rat (*Sigmodon arizonae plenus*)	CDFW: Species of Special Concern	Occurs in alluvial areas along the Colorado River in areas supporting marshy vegetation.	No suitable habitat in study area.	None	None	None	None

COMMON NAME SCIENTIFIC NAME	SENSITIVITY STATUS[1]	HABITAT REQUIREMENTS	DISCUSSION	POTENTIAL FOR OCCURRENCE WITHIN THE SOLAR ARRAY PROJECT BOUNDARY[2]	POTENTIAL FOR OCCURRENCE WITHIN THE PROPOSED GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE NORTHERN GEN-TIE LINE (BLM JURISDICTION)[2]	POTENTIAL FOR OCCURRENCE WITHIN THE SOUTHERN GEN-TIE LINE (BLM JURISDICTION)[2]
American badger (*Taxidea taxus*)	CDFW: Species of Special Concern	Coastal sage scrub, mixed chaparral, grassland, oak woodland, chamise chaparral, mixed conifer, pinyon-juniper, desert scrub, desert wash, montane meadow, open areas, and sandy soils.	Suitable badger habitat occurs throughout the vicinity in undeveloped areas. Some large burrows were observed within the study area but were likely kit fox and/or coyote. A live badger was found in 2012 three miles west of the Colorado River Substation (CDFW 2013).	High	High	High	High
Desert kit fox (*Vulpes macrotis arsipus*)	Calif. Code of Regulations: PFM	Suitable habitat for this fossorial mammal consists of arid open areas, shrub grassland, and desert ecosystems.	Suitable kit fox habitat occurs throughout the vicinity in undeveloped areas. A kit fox den was detected on the southern alternative.	High	High	High	Present
Fish							
Razorback sucker (*Xyrauchen texanus*)	ESA: Endangered CESA: Endangered CDFW: Fully Protected	Colorado River. Uses both quiet and swift waters and spawns in shallow water where there is abundant sand, gravel, and rocks.	There is no suitable habitat to support this species within the study area. This species occurs along the Colorado River (CDFW 2013).	None	None	None	None

[2] Species Potential for Occurrence
Low Potential–low potential to occur because suitable habitat present, but of marginal quality
Moderate Potential–moderate potential to occur because suitable habitat present; not found during surveys
High Potential–high potential to occur because suitable habitat present, and species known to occur within the vicinity; not found during surveys
Present–Species detected during Project surveys on adjacent areas.

Regulatory Framework

The Project must comply with various federal, State, and local laws. While some laws and policies provide constraints, others provide intent and direction for certain actions to occur. The following is a general overview of such guidance, which gives intent or direction for the proposed Project relevant to biological resources.

Federal

Endangered Species Act of 1973; 16 U.S.C. § 1531 et seq.; 50 CFR Parts 17, 222, and 402

The ESA includes provisions for protection and management of species that are federally listed as threatened or endangered or proposed for such listing and of designated critical habitat for these species. The administering agency for the above authority for non-marine species is the USFWS.

Migratory Bird Treaty Act: 16 U.S.C. § 703-711; 50 CFR Subchapter B

The Migratory Bird Treaty Act (MBTA) includes provisions for protection of migratory birds, including basic prohibitions against any taking not authorized by federal regulation. The administering agency for the above authority is the USFWS. The law contains no requirement to prove intent to violate any of its provisions. Wording in the MBTA makes it clear that most actions that result in "taking" or possession (permanent or temporary) of a protected species can be a violation of the act. The word "take" is defined as "pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to pursue, hunt, shoot, wound, kill, trap, capture, or collect (including nests, eggs, and feathers)."

Bald and Golden Eagle Protection Act

Bald eagle protection began in 1940 with the passage of the Eagle Protection Act, which was later amended to include golden eagle and was renamed. The Bald and Golden Eagle Protection Act makes it unlawful to import, export, take, sell, purchase, or barter any bald eagle or golden eagle, their parts, products, nests, or eggs. Take includes pursuing, shooting, poisoning, wounding, killing, capturing, trapping, collecting, molesting, or disturbing. Exceptions may be granted by USFWS for scientific or exhibition use, or for traditional and cultural use by Native Americans. However, no permits may be issued for import, export, or commercial activities involving eagles.

Clean Water Act (33 U.S.C. § 1251 et seq.)

The Clean Water Act (CWA) is the principal federal statute protecting navigable waters and adjoining shorelines from pollution. The Clean Water Act is administered by the EPA and the United States Army Corps of Engineers (USACE). The USACE is responsible for regulating the discharge of fill material into waters of the United States. Waters of the United States include lakes, rivers, streams and their tributaries, as well as wetlands. Since its enactment, the CWA prohibits the discharge of pollutants into waters of the United States without a permit. Section 404 of the CWA provides that whenever any person discharges dredged or clean fill material into Waters of the United States including, without limitation, wetlands, streams, and bays (e.g., while undertaking road construction, bridge construction, or streambed alteration), a permit is required from the USACE. Through field reconnaissance surveys and analyses of National Wetlands Inventory (NWI) and watershed data, it is unlikely that there are any jurisdictional waters of the United States.

Northern and Eastern Colorado Desert Coordinated Management Plan

The NECO Plan (BLM and CDFG 2002) is a landscape-scale, multi-agency planning effort that protects and conserves the natural resources of the California portion of the Sonoran Desert while also managing its use for humans. This plan was prepared under the same regulations that implement the FLPMA of 1976. The NECO planning area of the CDCA spans 5.5 million acres in the southeastern California Desert, and covers the Project area. The NECO Plan, which was adopted in December 2002, provides

management direction for a variety of sensitive species and habitats on BLM and National Park Service land, as well as the U.S. Marine Corps Chocolate Mountain Aerial Gunnery Range.

The NECO Plan primarily addresses recovery of the desert tortoise (*Gopherus agassizii*), conservation of a variety of other species, and modification of management of wild burro herds in the planning area, and updates policies regarding OHV use and public lands access and use. As part of its focus on desert tortoise recovery and sensitive species protection, the NECO Plan has established several Desert Wildlife Management Areas, which cover much of the designated critical habitat for the desert tortoise. Specifically, these Wildlife Management Areas consist of a system of integrated ecosystem management for special-status species and natural communities on federal lands, and regional standards and guidelines for public land health on BLM lands. The NECO Plan also establishes several Wildlife Habitat Management Areas, which include habitat for desert bighorn sheep and other sensitive species in the planning area (BLM and CDFG 2002).

California Desert Conservation Area Plan

The CDCA Plan guides the management of all BLM-administered lands in the Mojave, Sonoran, and a small portion of the Great Basin Deserts. In total, the CDCA Plan includes an area of approximately 25 million acres, 12 million of which are public lands. The primary goal of the CDCA Plan is to provide guidance for the overall maintenance of the land while simultaneously planning for multiple uses and balancing the human needs with the need to protect the natural environment.

The CDCA Plan includes 12 elements: Cultural Resources; Native American; Wildlife; Vegetation; Wilderness; Wild Horse and Burro; Livestock Grazing; Recreation; Motorized Vehicle Access; Geology, Energy and Mineral Resources; Energy Production and Utility Corridors; and Land-Tenure Adjustment. Each of the elements contains goals and specific actions for the management, use, development, and protection of the resources and public lands within the CDCA, and is based on the concepts of multiple use, sustained yield, and maintenance of environmental quality. In addition, each element provides both a desert-wide perspective of the planning decisions for one major resource or issue of public concern as well as more specific interpretation of multiple-use class guidelines for a given resource and its associated activities.

Wild Horse and Burro Act of 1971, as amended

Herd Areas are those geographic areas where wild horses and/or burros were found at the time of the passage of the Wild Horse and Burro Act in 1971. Herd Management Areas are those areas within Herd Areas where the decision has been made, through Land Use Plans, to manage for populations of wild horses and/or burros. Herd Areas boundaries may only be changed when it is determined that areas once listed as Herd Areas are later found to be used only by privately owned horses or burros, or the Herd Area boundary does not correctly portray where wild horses and burros were found in 1971. Chocolate Mule Mountains Herd Area is located approximately 1,000 feet away from the Southern Alternative's gen-tie line.

Executive Order 11312

This Executive Order from 1999 requires all federal agencies to prevent and control the introduction of invasive non-native species in cost-effective and environmentally sound manners. It established a nationwide Invasive Species Council and Invasive Species Advisory Committee to oversee and facilitate the implementation of the Executive Order.

State

California Endangered Species Act of 1984, California Fish and Game Code § 2050-2098

The CESA includes provisions for the protection and management of species listed by the State as endangered or threatened, or designated as candidates for such listings. CESA includes a requirement

for consultation "to ensure that any action authorized by a state lead agency is not likely to jeopardize the continued existence of any endangered or threatened species… or result in the destruction or adverse modification of habitat essential to the continued existence of the species" (§ 2090). Plants of California declared to be endangered, threatened, or rare are listed at 14 California Code of Regulations (CCR) § 670.2. Animals of California declared to be endangered, threatened, or rare are listed at 14 CCR § 670.5. The administering agency for the above authority is the CDFW.

California Fish and Game Code Section 3503, 3511, 4700, 5050, and 5515

These California Fish and Game Codes (CFGC) list bird (primarily raptor), mammal, amphibian, and reptile species that are classified as fully protected in California. Fully protected species are prohibited from being taken or possessed except under specific permit requirements. These Codes also prohibit the take, possession, or needless destruction of the nests or eggs of any bird, including birds of prey or their nests or eggs, except as otherwise provided by the code or any regulation made pursuant thereto.

Native Plant Protection Act (CFGC Section 1900 et seq.)

The California Native Plant Protection Act prohibits importation of rare and endangered plants into California, "take" of rare and endangered plants, and sale of rare and endangered plants. CESA defers to the California Native Plant Protection Act, which ensures that State-listed plant species are protected when State agencies are involved in projects subject to CEQA. In this case, plants listed as rare under the California Native Plant Protection Act are not protected under CESA but rather under CEQA.

California Fish and Game Code Sections 1600-1616 – Streambed Alteration Agreement

This Code requires that any person, State or local government agency, or public utility notify the CDFW and obtain a streambed alteration agreement before they begin any construction project that will divert, obstruct, or change the natural flow or the bed, channel, or bank of any river, stream, or lake, use materials from a streambed, or result in the disposal or disposition of debris, waste, or other material containing crumbled, flaked, or ground pavement where it can pass into any river, stream, or lake. In general, CDFW jurisdiction extends to the top of the stream or bank, or to the outer edge of riparian vegetation, whichever is wider.

Porter-Cologne Water Quality Control Act of 1969 (California Water Code Section 13000 et seq.)

The Porter-Cologne Water Quality Control Act provides State coordination with the CWA, which is described above. It provides a mechanism by which the Regional Water Quality Control Boards certify that federal actions that result in a discharge to waters, including federally issued CWA permits to ensure the compatibility of federal and State water quality guidelines, are in compliance with Section 401 of the CWA, which requires such federal actions to comply with state water quality standards. The act provides for the development and periodic review of water quality control plans (basin plans) that designate beneficial uses of California's major rivers and groundwater basins and establish narrative and numerical water quality objectives for those waters. Basin plans are primarily implemented by using the National Pollution Discharge Elimination System permitting system to regulate waste discharges to ensure that water quality objectives are met. Waste discharges may include fill, any material resulting from human activity, or any other "discharge" that may directly or indirectly impact Waters of the State relative to the implementation of Section 401 of the CWA.

California Desert Renewables Energy Conservation Plan

The California Desert Renewables Energy Conservation Plan (DRECP) is a Natural Community Conservation Plan being developed by a joint federal and State Renewable Energy Action Team (REAT) to provide for effective protection and conservation of desert ecosystems while allowing for the appropriate development of renewable energy projects. The REAT consists of the CEC, CDFW, BLM, USFWS, and counties impacted by the DRECP. The DRECP is intended to provide long-term endangered species permit assurances, facilitate the review and approval of renewable energy projects in the Mojave and Colorado deserts in California, and provide a process for conservation funding to

implement the DRECP. It is anticipated that the DRECP also would serve as the basis for one or more habitat conservation plans under the federal ESA and provide biological information necessary for consultation under ESA Section 10. The proposed Project would be located within the DRECP planning area. The DRECP is not yet final, and no decision has been made for the DRECP.

Local Ordinances

Riverside County General Plan

The Riverside County General Plan includes policies that address biological resources within the County boundaries. Countywide policies that seek to preserve biological resources are located in the Land Use Element and Open Space Element of the County General Plan, and include:

Land Use Element (LU)

Policy LU 8.1. *Provide for permanent preservation of open space lands that contain important natural resources, hazards, water features, watercourses, and scenic and recreational values.*

Policy LU 8.2. *Require that development protect environmental resources by compliance with the Multipurpose Open Space Element of the General Plan and Federal and State regulations such as CEQA, NEPA, the Clean Air Act, and the Clean Water Act.*

Policy LU 18.2. *Cooperate with the* [former] *California Department of Fish and Game (CDFG)* [now California Department of Fish and Wildlife (CDFW)]*, United States Fish and Wildlife Service (USFWS), and any other appropriate agencies in establishing programs for the voluntary protection, and where feasible, voluntary restoration of significant environmental habitats.*

Multipurpose Open Space Element (OS)

Policy OS 18.1. *Preserve multi-species habitat resources in the County of Riverside through the enforcement of the provisions of applicable MSHCPs* [Multiple Species Habitat Conservation Plans]*, if adopted.*

City of Blythe General Plan

Policies that seek to preserve biological resources are located in the Open Space Element of the City General Plan, and include:

Open Space and Conservation Element

Policy 15*: Protect habitats that are sensitive, rare, declining, unique or represent valuable biological resources in the Planning Area.*

Policy 16: *Preserve and protect populations and supporting habitat of special status species within the Planning Area, including species that are State or federally-listed as Rare, Threatened, or Endangered, all federal "candidate" species for listing and other species on officially adopted federal and/or State listings, and all California Species of Special Concern.*

Policy 17: *Minimize impacts to sensitive natural habitats throughout the Planning Area. In new developments, emphasis should be placed on protecting and preserving valuable and sensitive natural habitats, the comprehensive habitat mapping and biological resource inventory prepared, as part of Plan preparation, shall be consulted when reviewing development applications.*

Policy 18: *Preserve and protect areas determined to function as regional wildlife corridors, particularly those areas that provide natural connections permitting wildlife movement between designated sensitive habitats and all areas being considered for future conservation because of their high value.*

3.2.5 Cultural Resources

Cultural resources were inventoried and are described for the proposed Project and Alternatives. This section summarizes the results of a literature review, records searches, archaeological resource and historic built environment survey, and communications with Native American representatives regarding cultural resources that could potentially be impacted by the Project. The information in this section is based on the *Blythe Mesa Solar Project Archaeological Resource and Built Environment Survey, prepared by* POWER Engineers, Inc. (2013a) and the *Blythe Mesa Solar Project Archaeological Resource and Built Environment Survey, Transmission Line Alternatives Supplemental Report*, prepared by POWER Engineers, Inc. (2013b) (provided in Appendix D1 and D2, respectively, of this Draft EIR/EA). This section describes the affected environment and regulatory setting for cultural resources.

Environmental Setting

Prehistory

Paleoindian Period (San Dieguito) (12,000 to 7,000 before present [BP])

The Paleoindian period experienced profound environmental changes, as the cool, moist conditions of the Pleistocene (from 2.5 million to 12,000 years ago) gave way to the warmer, drier climate of the Holocene (from 12,000 years ago to present). The earliest record of habitation in eastern Riverside County occurred during the Paleoindian Period. Settlement patterns of this period suggest that habitation occurred along prehistoric lakeshores and on mesas near springs and washes. Away from the Colorado River, the Palo Verde Mesa area was not conducive to settlement due to the limited water resources available and was likely used as a travel corridor between the mountains and river (von Werlhof 2004). Within the larger Riverside County region, Paleoindian sites may be found on stable landforms, in protected caves above floodplains and valley/riparian environments, and along ridge systems and in mountain passes that may have served as travel routes.

The Paleoindian inhabitants were nomadic large-game hunters whose tool assemblage included choppers; percussion-flaked scrapers and knives; large, well-made, fluted, leaf-shaped, or stemmed projectile points (e.g., Lake Mojave, Silver Lake); crescents; heavy core/cobble tools; hammerstones; bifacial cores; and scraper planes (Rogers 1939, 1966; Warren 1968). The subsistence strategy used during the San Dieguito period focused primarily on hunting both large and small game as well as gathering plants throughout the seasons. Near the end of this period the climate began to warm, which caused the lakes and marshes to dry, resulting in the need for different subsistence and settlement strategies (Moratto 1984).

Archaic Period (Pinto and Amargosa) (7,000 to 1,500 BP)

The climatic patterns of the late Paleoindian period continued into the early Archaic period. The beginning of the late Archaic coincides with a period of increased moisture in the region. Research suggests the California desert environment was unstable during these periods, forcing the hunter-gatherers towards more hospitable regions (Crabtree 1981; Schaefer 1994; Weide 1974). However, late Archaic sites have been recorded in more southern portions of Riverside County's low desert near the Peninsular Ranges, where water was more available.

Late Archaic site types include residential bases with large, diverse artifact assemblages, abundant faunal remains, and cultural features; temporary bases; temporary camps; and task-specific activity areas. Diagnostic projectile points of this period include more refined notched (Elko), concave base (Humboldt), and small-stemmed (Gypsum) forms (Warren 1984). The mortar and pestle were used to process acorns, an important storable resource. *Haliotis* and *Olivella* shell beads and ornaments and split-twig animal figurines indicate that interior California occupants were in contact with populations on the California coast and in the southern Great Basin (Warren 1984).

Late Prehistoric (Patayan Complex) (1,500 to 150 BP)

A period of even more persistent drought began by 1,500 years ago, and conditions became significantly warmer and drier (Jones et al. 1999; Kennett and Kennett 2000). The dry period continued until 750 years ago (Spaulding 2001).

The Patayan Complex is marked by strong regional cultural development relative to the economic system and settlement patterns. In the Southern California desert regions, cultural development was heavily influenced by the Patayan culture of the lower Colorado River area (Warren 1984). This period includes a pre-ceramic transitional phase ranging between 1,500 and 1,200 years BP. The Patayan complex is distinguished from the transitional phase by the introduction of pottery using the paddle-and-anvil technique as well as the use of bow-and-arrow technology. Also noted is the use of floodplain agriculture (Rogers 1945). These technological advancements are believed to be from Mexico or the ancestral Pueblo cultures of the Southwest deserts (McGuire and Schiffer 1982; Rogers 1945; Schroeder 1979).

Diagnostic artifacts include Saratoga Springs projectile points, small triangular projectile points, mortars and pestles, steatite ornaments and containers, perforated stones, circular shell fishhooks, numerous and varied bone tools, and bone and shell ornaments (Schaefer 1994). Elaborate mortuary customs and extensive trade networks are also characteristic of this period. Additionally, abundant amounts of obsidian were being imported into the region from the Obsidian Butte source that had been exposed by the desiccation of Lake Cahuilla (Warren 1984).

According to Schaefer and Laylander (2007), the preponderance of evidence suggests that pottery was not introduced or was rarely used in the California desert area before *Anno Domini* (A.D.) 870 to 1010. Two ceramic types have been identified as the most prevalent for the Palo Verde Valley area, Lower Colorado Buffware and Tizon Brown Ware. Harner (1957) observed that in the Chuckwalla Valley (20 miles west of the Project) the frequency of Lower Colorado Buff was double that of Tizon Brown. When this pottery was compared and cross-dated with a collection from the Bouse Site in Arizona, Harner (1957) found that the pottery from the Chuckwalla Valley could date between A.D. 1300 and 1900. However, Griset (1996), cited in Schaefer and Laylander (2007), also saw evidence of pottery in the region as early as A.D. 800.

Lower Colorado Buffware is made from riverine and lacustrine clay, usually with fine grains of subangular to sub-round quartz, feldspars, and other opaque spars. Most vessels are highly oxidized due to the firing process. The surface finish is typically smoothed with faint wipe marks left by mops. The larger vessels may display anvil marks on the interior surfaces. A thick cream-colored scum coat is common in the desert regions, and stucco treatment is also common along the Colorado River and in the desert. The surface color is usually tan with pink tones. Recurved rims are common, polish is rare, and decorations often include fingernail impressions, in casing and punched holes. Colorado Buff dates to Patayan III (A.D. 1500 to post-1900) (Waters 1982).

Tizon Brown Ware is made from clays from decomposing granite outcrops in the California-Colorado desert regions, and usually contains higher iron content. The vessels are typically reddish brown and contain little to no temper. Both Tizon Brown and Lower Colorado Buff were usually made using coils, smoothed and shaped by a paddle and anvil (Lyneis 1988).

By the late Prehistoric period there appears to have been a transition to more mobile patterns of travel and trade between the Colorado River and Lake Cahuilla (Pendleton 1984). Long-range travel for resource procurement and trade resulted in a system of trails through the Colorado Desert. The increased mobility along the trail system allowed the opportunity for interaction between neighboring tribes. As the Spanish began to explore the area, native trails and trade routes were used and expanded.

In an ongoing study, Laylander and Schaefer (2010) have applied a regional perspective to evaluate and treat cultural resources within a broad landscape approach. The current Project falls within their Prehistoric Trails Network Cultural Landscape area, which includes the Palo Verde Valley and McCoy Wash and Palen Valley. No historic trails are documented within the proposed Project solar facility site or alternative gen-tie line ROWs. For this reason and because of the extensive past military-related and

agricultural disturbance of the Project area, the Prehistoric Trails Network Cultural Landscape is not analyzed in detail in this Draft EIR/EA.

Three prehistoric trails are outside the Project boundaries but in the Project vicinity; these were likely used to travel to and from springs and other water sources. McCarthy (1993) explained that trails in the McCoy Springs region are un-bordered and do not indicate evidence of deliberate construction.

Early research in the area noted recognizable trail types, including major long distance, minor long distance, and subsidiary trails between settlements and resource areas (Rogers 1941). McCarthy (1993) defines two types of trails, primary and secondary. Primary trails are based around a destination that is fixed on the landscape, such as a spring. McCoy Springs was the destination spot for all of the trail segments in the current Project vicinity. Secondary trails branch off from primary trails. McCarthy identified CA-RIV-53 (known as the Halchidhoma Trail), east and northwest of the Project, as the predominant trail that leads to McCoy Springs. The trails along the southern flank of the McCoy Mountains probably emanate from the Colorado River (Palo Verde Valley) and lead toward the Chuckwalla Valley. Between the McCoy and the Chuckwalla Mountains, several springs (McCoy, Chuckwalla, and Corn Springs), tanks (Palen and Mule Tanks), and dry lake beds (Ford Dry Lake and Palen Lake) were linked with a network of trails. The trails that were found within the desert pavement setting were in excellent condition. These trails include CA-RIV-53; CA-RIV-885, less than a mile southwest of the Project; and CA-RIV-3673, less than a mile northeast of the Project. The historic Bradshaw trail, discussed below, followed ancient Native American trails that linked water sources across the Colorado Desert. These trails passed through the San Gorgonio Pass, turned south and ran to the Salton Sink and between the Orocopia and Chocolate mountains, skirted the southern edge of the Chuckwalla Range, crossed through the Mule Mountains, and reached the Palo Verde Valley.

Other trails lead toward canyons containing temporary water sources. Petroglyph sites have been documented in these canyons; two short trail segments that lead to a large canyon southeast of McCoy Peak have been documented outside the Project but within the Project vicinity. In addition to water sources, other resource areas would include lithic quarries and assay areas. A line of pebble terraces line the southern flank of the McCoy Mountains. Several extremely large prehistoric lithic sources and assay sites have been recorded in these terraces. Trail segments between these sites have been documented. One segment, CA-RIV-3671, is within one mile of the Project (von Werlhof 1987). McCarthy speculates shorter trail segments in the area of McCoy Wash were used to connect specialized activity areas within larger habitation areas (McCarthy 1993).

Trails were also used for trade routes. Trade between Southern California and the Southwest may have begun more than 9,000 years ago (Ruby 1970), but the predominant trading activity ranged between A.D. 900 and A.D. 1300. Exchange items included California marine shell and Southwestern pottery. Johnston and Johnston (1957) found segments of trails from the Colorado River through the San Gorgonio Pass and into Riverside County. The system connected the Palo Verde Valley to the McCoy Mountains through the Chuckwalla Valley into the Chuckwalla Mountains. Trails are also discussed in Warren and Roske (1981) and Johnston (1980).

Trails are also a significant element in the Native American sacred landscape; they link the spiritual world to the natural landscape. Trails have been marked with rock shrines and artifacts such as pottery drops and flaked stone scatters, particularly white quartz. Songs and stories contain named places such as mountains, water sources, valleys, and other geographical locations along known trails (Fowler 2009).

Ethnography

The Colorado Desert area of Riverside County is within the ethnographic boundaries of several different eighteenth and nineteenth century Native American groups.

Colorado River Peoples: the Quechan, Halchidhoma, and Mojave

The first Europeans to encounter and document the traditional inhabitants of the Lower Colorado River area were the Spanish, followed by American explorers. Kroeber (1920, 1925) conducted extensive

fieldwork at the turn of the twentieth century; in particular, he studied the Mojave tribe in the Needles area. Spanish missionary influence did not reach the desert cultures, which enabled them to retain much of their language, religion, and cultural practices. Early ethnographers were able to conduct fieldwork and documented many details about oral histories, ritual and burial practices, and life-ways practiced prior to contact and those during the first half of the twentieth century. Malcolm Rogers studied the Colorado River tribes in the 1930s and documented information that included the lithic and ceramic technologies.

After A.D. 1000, the Colorado River tribes appear to have become more mobile and extended their travel between the river and Lake Cahuilla, and consequently expanded their resource procurement patterns (Pendleton 1984). This resulted in the development of an extensive trail network throughout the Colorado Desert. Evidence of travel and trade is noted by the presence of pottery drops and shrines lining the trails (McCarthy 1993). The trails network was also a major component of the tribes' belief system, interconnecting important geographical locations and ceremonial sites with song cycles and rituals.

Lithic quarries along various mountain ranges were used for tool material; springs within these mountains provided water. Several springs are located within a day's travel of the Project area; in addition to McCoy Springs, Corn and Chuckwalla springs are less than 30 miles to the west.

The lower Colorado River region, including the Project area, was inhabited by numerous tribes at the time of the first Spanish contact. Alarcon and Diaz were the first to travel up the Colorado River in 1540; their description of the interaction between tribes indicates shifting boundaries and inter-tribal hostilities. (Forbes 1965). A later expedition by Oñate in 1605 documents several tribes, including the Halchidhoma, the Quechan, and the Mojave, at various points along the river. By 1774, the Anza Expedition noted the Halchidhoma living between the Mojave and Quechan territories near Parker, Arizona. Historical accounts describe constant conflict among the tribes, with the Quechan and Mojave against the Halchidhoma. Ultimately, the Halchidhoma left the area and resettled in the mid-1800s in the Gila River area.

Settlement was determined primarily by proximity to permanent water sources. Villages and camp sites were most often in the foothills and less frequently on the open areas of the desert floor and mesas, depending on the availability of water. Tribal boundaries and territories were dynamic as a result of interactions and warfare between tribes (Dobyns et al. 1963; Kroeber 1925).

Like some of the other river Yuman tribes, the Mojave focused on agriculture, producing close to half of their dietary needs from crops, including maize, squash, melons, beans, and a variety of grasses (Bee 1983; Castetter and Bell 1951). Similarly, the Quechan also relied on agriculture as well as fish from the Colorado River. In addition, both small game and large game were hunted, adding important dietary protein.

The Colorado River tribes share similar beliefs that are strongly linked to dreaming and ritual songs that apply to daily life and personal knowledge. These beliefs are based on real places that are visited physically or in dreams (Kroeber 1925). Forbes noted that religion, cultural identity, various aspects of daily life, and the landscape on which the tribes lived were intricately intertwined. Important ceremonial locations include intaglios, petroglyphs, lithic scatters, and cleared circles along the Colorado River and in the surrounding hills. As previously mentioned, one key component of the cultural landscape is the regional trail system (Forbes 1965).

Chemehuevi

The Chemehuevi tribe is the southernmost group of the Southern Paiutes (Kelly and Fowler 1986). Their territory included the western side of the Colorado River into the Palo Verde Mountains and north toward Cadiz Dry Lake.

The Chemehuevi share many cultural elements with the Mojave, including habitation structures, ground stone tool types, and spiritual beliefs. The Chemehuevi were organized in small mobile groups who traveled widely, interacting with neighboring tribes. They subsisted on small game, hunting as far west as San Bernardino, and on harvesting seasonal plant resources throughout the region. They hunted with the Quechan in Arizona and the Serrano in Tehachapi, and were reported to have collected abalone in the

Santa Barbara Channel and to have journeyed east to the Hopi villages (Kelly and Fowler 1986). They were not known to have used pottery but rather chose basketry and other woven implements, often decorated. The Chemehuevi who settled along the Colorado River lived in relatively permanent structures and utilized agriculture to a greater extent than related groups to the west (Laird 1976). Historically, they grew a variety of crops including vegetables, beans, winter wheat, and grasses.

Chemehuevi spiritual beliefs include a sacred landscape that incorporates both the spirit world and the natural world. These rituals include songs and dreams that are the basis of their daily lives, linking their beliefs, material existence, and the cultural landscape. Kroeber states that knowledge is acquired by each man according to his dreams (Kroeber 1925). The "Salt Song" describes a ceremonial trail that traverses through three states and explains the significance of the mountains and the medicines found in them.

Cahuilla

The Cahuilla are one of several groups that migrated into California from the Great Basin; although the specific time, duration, and process is unclear, it is estimated to have taken place around 1,500 BP (Kroeber 1925; Laylander 1985). The Cahuilla's traditional territory encompassed diverse topography ranging from 273 feet below sea level at the Salton Sink to 11,000 feet amsl in the San Bernardino Mountains. The Cahuilla's territory extended from the summit of the San Bernardino Mountains in the north to the Chocolate Mountains and Borrego Springs in the south. Its eastern border included the Colorado Desert west of Orocopia Mountain, and its western border included the San Jacinto Plain near Riverside and the eastern slopes of Palomar Mountain (Bean 1978).

Numerous land-holding clans claim territory within this area, each of which ranged from the desert to the mountain areas. Clans could include more than one lineage, each of which had independent community areas that were owned within the larger clan area (Wilke and Lawton 1975).

Cahuilla villages usually were in canyons or along alluvial fans near adequate sources of water and food plants. The immediate village territory was owned in common by a lineage group or band. The other lands were divided into tracts owned by clans, families, or individuals. Trails used for hunting, trading, and social interaction connected the villages. Each village was near numerous sacred sites (places of importance such as locations of traditional ceremonies or activities) that included rock art panels (Bean and Shipek 1978).

Cahuilla belief system and oral tradition indicate that when Lake Cahuilla dried up, the desert floor was settled; 17 or more rancherias have been identified in Coachella Valley. These rancheria locations are associated with hand-dug wells, springs, or palm oases. Water collection and conveyance features and associated agricultural fields have been documented from the early 1800s (Wilke and Lawton 1975).

Euro-American History

European presence in the Colorado River region began with explorations in the sixteenth century. Permanent settlement occurred in the mid-nineteenth century as a result of the development of transportation and water conveyance. Exploration was primarily for travel routes in search of interior waterways and from Mexico north toward Monterey for the establishment of the California missions by the Spanish. The end of the Mexican War of 1846 to 1848, the discovery of gold in California in 1849, and the establishment of California as a state on September 9, 1850 all contributed to a steady influx of non-Hispanic settlers into the area. Later, mining, agriculture, and military training brought settlement to the Riverside County area.

Transportation

Prior to the European presence in the Colorado Desert area, transportation was limited to foot trails used by the Native Americans. As the Spanish began to explore the area, these native trails and trade routes were further used and expanded. One of the more important routes, known as the Bradshaw Trail, was developed as the result of the search for gold in the region, specifically in the area of La Paz, along the

eastern side of the Colorado River (Gunther 1984; Johnston 1972, 1987) and north of the Project area. William D. Bradshaw, a forty-niner working in the San Bernardino County area, was determined to find an overland route from the Pacific Ocean to the Colorado River, where gold had been recently discovered in what is now Ehrenberg. Bradshaw had previously mined for gold in Sutter's Mill in 1849, and anticipated La Paz to become a gold strike boom-town. To accommodate the expected influx of miners headed toward La Paz, Bradshaw recruited a group of eight men to scout out a direct route.

Bradshaw worked with Chief Cabazon, the leader of the Desert Cahuilla, and a Coco Maricopa Indian mail runner to map a route using an ancient native trail. The Bradshaw Trail passed through the San Gorgonio Pass through Palm Springs, then turned south and ran through Martinez to the north side of the Salton Sink and between the Orocopia and Chocolate Mountains ranges. The route then skirted the southern edge of the Chuckwalla range crossed through the Mule Mountains and reached the Palo Verde Valley. Bradshaw also established a ferry service to cross the Colorado River and proceeded to promote his new trail and ferry enterprise (Gunther 1984; Johnston 1972, 1987). The Bradshaw Trail is 5.5 miles south of the Project area.

Also paramount to the development of the Colorado Desert was the arrival of the Southern Pacific Rail Road (SPRR), a transcontinental railroad system. The SPRR was founded as a land holding company in 1865 and acquired various smaller railroad companies that would eventually link New Orleans, Texas, New Mexico, Arizona, and California through Los Angeles and then north into San Francisco through to Portland, Oregon. Numerous communities sprang up along the route and greatly accommodated the mining boom in the local area (Vredenburgh et al. 1981). The railroad was instrumental in settlement of the Colorado Desert areas by providing access to immigrants as well as shipping consumer goods and produce between the east and west coasts (Fickewirth 1992). The SPRR reached Yuma, Arizona in 1877, and links north on the river were provided by commercial river boat traffic (Vredenburgh et al. 1981). Later, to facilitate the mining activities in the Blythe area, a spur was constructed to the Atchison, Topeka, and Santa Fe Blythe-Ripley Line in 1916.

Mining

With the signing of the Treaty of Guadalupe-Hidalgo in 1848, the southwest came under the control of the United States. The Colorado Desert was the scene of prolonged mining from 1850, with the beginning of the gold rush in California. The small town of La Paz, 45 miles northeast of Blythe on the eastern bank of the Colorado River, was a boomtown in the 1860s (Wilson 1961). The mid-1860s saw the town of La Paz swell in population to over 5,000, but by 1870 the miners had gleaned most of the gold-bearing ore from this site.

Mining and prospecting were primarily focused in the mountains and high desert north of Blythe, and small-scale mining occurred from the 1860s until after the Great Depression in the 1930s (Morton 1977). Although gold was found only in small amounts, mining of gypsum and manganese were more successful ventures. To the north in the McCoy Mountains, several significant manganese mines provided ore for armaments during both World Wars I and II (Butler 1998). Other minerals that were mined from the areas in the Project vicinity include fluorite, copper and uranium (Warren et al. 1981).

Homesteading and Agriculture

The passage of the Homestead Act in 1862 and the Desert Land Act in 1877 were instrumental in the settlement of the Lower Colorado River area. The Homestead Act offered the opportunity for United States citizens to file a claim on 160 acres or less of land for $1.25 per acre. The Act stipulated that the claim be for purposes of actual settlement and cultivation, and the claimant was required to "improve" the plot by building a dwelling and cultivating the land. After five years on the land, the original filer was entitled to the property, free and clear (National History Day n.d.).

The Desert Land Act was similar to the Homestead Act in that it was enacted to encourage and promote economic development of the desert lands of the western states. This act also required the filer to irrigate and cultivate the land within three years. A married couple could pay $1.25 per acre for a maximum of 640 acres, whereas a single man would receive half the land but pay the same price. Proof of irrigation

was required for the filer to obtain title. This act was revised to offer a maximum of 320 acres with proof of irrigation required within four years (Library of Congress n.d.).

Agriculture in the Palo Verde Valley was made possible by the construction of canals and pipelines as well as the securing of water appropriations. Thomas Blythe came to the lower Colorado River area and established water rights along the Colorado River. His efforts in irrigation and cultivation of the land were successful. The first irrigation project was not completed until 1883, after his death (Warren 1981), but eventually 40,000 acres were irrigated as a result of his diverting water from the Colorado River (Blythe Chamber of Commerce 2011). The valley was still subject to flooding, however, until after the completion of Boulder Dam in the 1930s.

World War II Desert Training Center/California-Arizona Maneuver Area

Soon after the United States entered World War II, General George S. Patton, Jr. was assigned the task of developing a training center to prepare Army troops for combat against German forces in North Africa. Patton identified an area in the California desert that offered realistic terrain and combat conditions to train the troops. The lack of water, extreme heat, and difficult terrain as well as the remote location would assist preparing troops for mobilization and combat tactics. Ultimately, training missions were both ground and air; all manner of equipment and battle strategies were tested and perfected there (Bischoff 2000).

Patton established base operations headquarters at Camp Young, near Indio, and began training troops in April 1942. The Desert Training Center (DTC) facility extended from Desert Center in California to the Colorado River, as far north as Searchlight, Nevada and as far south as Yuma, Arizona. To accommodate the massive number of troops brought to the region, several desert airfields were taken over by the Army in 1942, including the airfield that was to become Blythe Army Air Base (BAAB). The name of the DTC was changed to the California-Arizona Maneuver Area (C-AMA) in October 1943, and the mission of the C-AMA was expanded to include simulation of large-scale operations and logistics beyond exclusively desert warfare tactics.

The DTC/C-AMA consisted of 11 major camps, seven in California and four in Arizona. The larger camps included Camp Iron Mountain, Camp Granite, and Camp Coxcomb, north of Desert Center. All of the facilities were connected by railroads and major roads (Vrendenburgh et al. 1981).

The DTC/C-AMA was where actual battle simulation was first used. The training offered in surviving the elements, tactical mobility, and mastering ordinance and engagement provided unparalleled experience for troops and commanding officers. In April 1944, the facilities began evacuations and closing, eventually being turned back to the United States Department of the Interior and private landowners (Bischoff 2000).

Blythe Army Air Base

The Project area is on the eastern side of BAAB that, beginning in 1942, supported the military training missions associated with the DTC/C-AMA and later provided aerial bombardment training between 1942 and 1944. As a cultural resource, BAAB was documented in 2010 as P-33-18837 and evaluated for the National Register of Historic Places (NRHP) and California Register of Historical Resources (CRHR); a brief summary based on Mitchell (2010a, 2010b) and information provided by Art Wilson (2008, personal communication 2011), a local historian, is provided below.

Under the Civil Aeronautics Act of 1938, the Civil Aeronautics Administration was charged with developing civilian airfields throughout California that could be used for defense. BAAB had humble beginnings in 1940 as a private, unpaved airstrip, originally known as Intermediate Flying Field Site 21. In addition, Site 21 was intended for emergency landings for flights between Los Angeles and Phoenix. The following year (1941) the Works Progress Administration provided funds to upgrade the airfield to two paved runways as part of the National Defense Program, with Riverside County sponsoring the project and maintaining the airfield.

In February 1942, General Patton was tasked to identify a location suitable for training troops in desert warfare as preparation for deployment to North Africa. The selected location became the DTC.

Construction was planned for DTC airfields at Thermal, Desert Center, Rice, and Shaver's Summit (now Chiriaco Summit). Because construction for the Site 21 airfield outside Blythe was already underway, it was incorporated into General Patton's DTC operation and used immediately for air support until the four new airfields became operational.

On April 7, 1942, approval was given for Site 21 to become BAAB, and improvements were begun in preparation for the arrival of the 46th Bombardment Group, whose initial mission was to provide medium bomber crews in support of Patton's rigorous desert warfare training. This group was joined by the 3rd Observation Squadron to perform observation missions in support of the army ground forces on maneuvers at the DTC. For five months, General Patton oversaw the operations of the DTC, including BAAB. In September 1942, General Henry "Hap" Arnold and Lt. Col. Richard Lee took over command of the base from General Patton; by the end of that year the base population was 800 officers and 5,400 enlisted men (Wilson 2008).

Construction continued on the base throughout 1942; by December a deep water well, a small hanger, an engineering building, the base theater, four warehouses and 60 barracks had been completed, and four runways with aprons had been paved and were in use. However, by the end of 1942, DTC airfields were operational at Thermal, Rice and Desert Center and support from BAAB was no longer needed. At that point, BAAB was relieved of its DTC air support role and changed to heavy bomber training under the 2nd Air Force. The 34th Bombardment Group was assigned to BAAB; its mission was training in B-17 Flying Fortress and B-24 Liberator aircraft (Wilson 2008). In total, BAAB's direct association with the DTC lasted eight months, from April 1942 to the end of the same year, and its association with General Patton lasted only five months.

In 1943, the base hospital, an officer's club, and the pool were opened for use. Also, a mess hall, a base chapel, a barber shop, and additional hangars were completed. Numerous bombardment groups trained at the base for the next two years. Included in the troops assigned to the base for short periods were the Women's Army Auxiliary Corps and the 99th Fighter Squadron, also known as the Tuskegee Airmen (Wilson 2008).

By March 1944, the training mission at BAAB began to gear down. Most of the troops had completed training and were deployed to new assignments; no new crews were being assigned to BAAB for training. The DTC/C-AMA was closed in 1944; BAAB became an alternative landing site for March Field in Riverside. BAAB remained staffed for providing emergency landing for airplanes unable to land at their designated home fields due to weather. By October 1945, BAAB was downgraded to an airfield, being closed and surplus government property the following year. It continued to be used for various training purposes until 1948 when the government transferred the property to the County of Riverside, which currently operates a portion of the property as the Blythe City Airport. Farming on the airfield property during the 1970s and 1980s destroyed most of the original buildings and features (Wilson 2008).

City of Blythe

Thomas Blythe, an Englishman, arrived in the area in 1882 in search of gold and real estate development possibilities. Having been successful in real estate investments in San Francisco, Blythe came to the lower Colorado River area and established water rights along the Colorado River. His efforts in irrigation and cultivation of the land were successful (Blythe Chamber of Commerce 2011). Further development of the desert lands into fertile agricultural fields continued. Most noteworthy was the formation of the Palo Verde Land and Water Company by Frank Murphy, Ed Williams and W.A. Hobson.

The City of Blythe was incorporated in 1916. In that same year, the California Southern Railroad built a railroad to the community. Even with the railroad and despite the development of irrigation, growth was limited because of the threat of flooding from the Colorado River. An especially devastating flood occurred in 1922. Development of Hoover Dam and other structures in the 1930s stabilized the flow of the Colorado River, leading to an improved economy and population growth.

Historic Background and Records Search

Records searches were conducted at the Eastern Information Center, housed at the University of California, Riverside on April 7, 2011 and May 31, 2012. California Historical Resources Information System records were reviewed to determine the location of previously recorded archaeological and historic architectural resources and the locations of prior cultural resource surveys within one mile of the area of potential effects (APE). The APE is defined for this Project as the land within the boundaries of the proposed solar facility site and land within a 300-foot corridor along each of the gen-tie alternatives. In this section, APE is used interchangeably with "Project area." Also consulted were the NRHP, National Park Service (NPS) Focus CRHR, California Historic Landmarks (CHL) lists, and California Points of Historic Interest. In addition, the online BLM General Land Office patent information was consulted. Also consulted were Art Wilson, a local historian, the General George S. Patton Memorial Museum and the Palo Verde Historical Museum and Society.

The records searches conducted at the Eastern Information Center indicated that 34 cultural resource studies were previously conducted within one mile of the solar facility site and the collective area covered by a one mile buffer on each side of the three gen-tie route alternatives). Fourteen of the previous surveys occurred entirely or partly within the APE, but only nine percent (360 acres) of the APE had been surveyed.

A total of 250 cultural resources were previously recorded within one mile of the Project area (see Appendices C1 and C2, respectively, for information about cultural resources identified in the records searches). Twenty cultural resources were previously recorded within the Project APE.

Of the 250 resources identified during the record searches, 163 are archaeological sites, 75 are isolated finds, four are historic built resources (transmission lines), and eight have missing information. Of the archaeological sites, 60 had prehistoric components, 82 had historic components, and 21 had both prehistoric and historic components. Of the isolated finds, 45 had prehistoric artifacts, 24 had historic artifacts, four had both prehistoric and historic artifacts, and two inventory forms lacked descriptions of the artifacts. The prehistoric sites are predominantly lithic and ceramic scatters. The historic sites are primarily refuse deposits, many related to World War II training in the area, but also include survey markers, fence lines, and roads.

Field Inventory

An intensive BLM Class III archaeological and historic built environment survey was conducted of the area that could potentially experience direct impacts from construction and operation of the proposed Project and Alternatives. The survey covered the APE, defined as the solar array site boundary and a 150-foot area on each side of the centerline of the proposed and alternative gen-tie routes. The APE included privately owned lands and public lands managed by the BLM. During the surveys, archaeologists walked parallel transects, using 15-meter (50-foot) intervals, to locate archaeological and architectural resources within the APE. The ground surface was visually examined for evidence of prehistoric or historic archaeological materials and historical structures. Ground visibility was excellent. Visible ground surfaces were examined, including fence lines, drainage channels, and other exposures. No subsurface surveys (e.g., shovel test pits) were conducted. A sub-meter GPS was used to document the location of each cultural resource.

The archaeological field survey was conducted in five sessions between April and June, 2011, and between June and July, 2012. Isolated finds were recorded at the time of discovery by collecting GPS data, photographs, and measurements of the artifact. The archaeological sites were point-located when discovered and later recorded during a later session. Overview photographs of survey areas and comprehensive field notes were also taken. In addition, a site visit of selected areas of the solar generation site was conducted by County Archaeologist Leslie Mouriquand and Riverside County Historic Preservation Officer Keith Herron on November 22, 2011.

The records search results, existing and new archaeological sites and isolated finds within the solar facility site and gen-tie line corridor alternatives, and other details of the surveys are described in detail in Appendices C1 and C2, respectively. There are a total of 55 resources within the APE. There are seven prehistoric archaeological sites, 12 historic archaeological sites, one multi-component site with prehistoric and historic artifacts, two historic architectural resources (transmission lines), one proposed historic district that includes archaeological remains plus a single standing building, and 32 isolated finds (nine are prehistoric, 21 are historic, and two have both prehistoric and historic artifacts). The survey results for existing and new cultural resources with eligibility recommendations within the APE are summarized in Table 3.2.5-1 and discussed below.

Solar Generation Site: The field survey resulted in the identification of five newly recorded archaeological sites and 23 isolated finds. Of the five archaeological sites, one is prehistoric (P-33-020001) and four are historic (P-33-019996; P-33-019997; P-33-019999; P-33-020000). Of the isolated finds, 16 are historic and seven are prehistoric (five contain ceramic sherds and two contain flakes). During the field survey, four previously documented historic resources were revisited and their site records updated. The previously documented historic sites consist of one refuse scatter (P-33-009186); two architectural resources (P-33-012532; P-33-014083); and the BAAB Historic District (P-33-018837).

Proposed Gen-tie Route: Two isolated finds were identified, one of which is prehistoric (P-33-021136) and the other historic (P-33-021137). During the field survey, one previously documented cultural resource (P-33-019770) was revisited but not re-recorded because it was recorded in 2011 and conditions had not changed.

Northern Alternative Gen-tie Route: One newly recorded historic archaeological site (P-33-021133), one historic isolated find (P-33-021135), and one prehistoric isolated find (P-33-021134) were identified. Two previously documented cultural resources (P-33-017319, a historic refuse scatter; and P-33-019612, a historic isolated find) were revisited but not re-recorded because they were recorded in 2008 and 2011, respectively; and the site conditions had not changed.

Southern Alternative Gen-tie Route: One newly recorded historic archaeological site (P-33-021132); two newly recorded prehistoric archaeological sites (P-33021130, and P-33-021131); and one prehistoric isolated find (P-33-021134) were identified. Twelve previously recorded resources were within this alternative alignment: four historic archaeological sites (P-33-014150, P-33-019682, P-33-019703, and P-33-019736); four prehistoric archaeological sites (P-33-019733, P-33-019737, P-33-019739, and P-33-019760); one multi-component site with prehistoric and historic artifacts (P-33-019714); and three isolated finds (two historic: P-33-019704, P-33-019712; and one prehistoric: P-33-020317). These previously recorded sites were revisited but not re-recorded because they were recorded as recently as 2011 and site conditions have not changed.

TABLE 3.2.5-1 CULTURAL RESOURCES WITHIN THE APE[1]

PRIMARY NUMBER	TRINOMIAL	DESCRIPTION	LAND OWNERSHIP	AGE	NRHP / CRHR ELIGIBILITY DETERMINATION
Within Solar Facility Site APE					
P-33-009186	--	Refuse scatter – 10x30 meters – WW II dump containing food cans, miscellaneous metal pieces, and other debris.	Private	Historic	Not Eligible
P-33-012532	--	Transmission line – 100 feet x 2.5 miles (within the APE). 161 kV transmission line with wooden pole, H-frame structures.	Private	Historic	Not Eligible
P-33-014083	--	Transmission line – 125 feet x 1.9 miles (within the APE). 161 kV transmission line with wooden pole, H-frame structures.	Private	Historic	Not Eligible

PRIMARY NUMBER	TRINOMIAL	DESCRIPTION	LAND OWNERSHIP	AGE	NRHP / CRHR ELIGIBILITY DETERMINATION
P-33-018837	--	Blythe Army Air Base (BAAB) Historic District. Remains of the former military are base in the vicinity of the Blythe Municipal Airport. A portion of the BAAB (approx. 383 acres) extends into the Project APE, including one standing utility building; remains of demolished warehouses, barracks, and hospital; other infrastructure (fire hydrants, manholes); and three clusters of refuse.	Private	Historic	Elements within APE – Not Eligible
P-33-019996	CA-RIV-10165	Refuse scatter – 66x42 meters – Sparse scatter of bottles, jars, cans, and miscellaneous metal debris.	Private	Historic	Not Eligible
P-33-019997	CA-RIV-10166	Refuse scatter – 50x10 meters – Two concentrations of debris, primarily cans and glass.	Private	Historic	Not Eligible
